

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.

+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.

+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.

Introductory Lecture

ON

SOME OF THE PROBLEMS OF PATHOLOGY.

Delivered at Guy's Hospital, May 7th, 1887,

BY JAMES F. GOODHART, M.D., F.R.C.P.,

PHYSICIAN TO THE HOSPITAL, AND LECTURER ON PATHOLOGY AT THE MEDICAL SCHOOL.

GENTLEMEN,—Pathology, as something more than morbid anatomy, is an attempt to interpret morbid changes—an attempt to unravel not so much the conditions themselves as how they come about, the process which produces them, and the successive steps by which the result is reached. It deals, therefore, with morbid function as well as with structural change, and thus it becomes and is the complement to physiology—if you like so to call it, it is the physiology of decay. In illustration of this take the body of one who has died of old age. There may be nothing throughout it to show *why* it is dead. The organs are simply too small; it cannot even be said that they are too small when it is remembered that the work required of them was so little. Yet here is death. We call it senile atrophy in the certificate, to bring it within range of municipal conception—to give it, in other words, a morbid anatomy. I want, however, to impress upon you that such a case has no morbid anatomy. The viscera are small because little was asked of them, but that little they did well. On the other hand, senility is not wanting in a pathology. "Physiology played out" is the only name I can find for what has nothing to show of its nature, save the fact, the dread reality of death. We may take yet another example with advantage to the full illustration of our meaning. Let it be the grey hair, or if you like it the autumn leaf—for disease is not limited to one world of life. What of morbid anatomy have we in these? Only a change of tint. Nothing, indeed, to show why the end has come. Yet each of these, the silvery lock, the sere and yellow leaf, has its pathology, but it is not one that can be detected by the most minute inspection; it can only be discerned by the study of such changes in general, and of their obvious relation to physiological circumstance. From such as these it is that we arrive at the suggestion that rhythm is an important element of consideration. We are all set—our several parts are all set—to a fore-ordained time, determined for us by the sum of the conditions of bygone ages concentrated down into heredity. Our present environment adds for *us* only the accidental, although something towards the general determining power upon our offspring. And it is quite conceivable that if other disturbing causes did not interfere; if geological conditions, for instance, should so far slowly alter, as to have no appreciable influence on living organisms; if the struggle for existence could pause in its headlong career towards the competitive throat-cutting which threatens to reduce us to a refined Ishmaelism in the not far distant future—if, I say, such influences as these could be eliminated, then this time-setting might come to be the life closure, not of an exceptional individual only, but of all animal life; the average duration of existence, epoch by epoch, would be gradually curtailed, until time should be no longer. But were that all that could be said about rhythm and disease, save as a matter of interesting speculation, either subject might well be left alone. It is, however, not so; rhythm or periodicity plays a considerable part in many a pathological process, and plays it so prominently that perforce one must consider it. It is one of the mysteries of pain which very early in your career will insist upon being combated. Not even the ghosts of Christmastide, when disturbing the midnight watches of Ebenezer Scrooge, exhibited more inexorable punctuality than do some of the worst forms of neuralgia. Pyrexia is ofttimes rhythmic in the regularity of its rise and fall. Many an acute illness will have its diurnal hours of amelioration and relapse. Death itself may come as the climax of a rhythmic order such as this. No matter to what part of the economy we look—whether to the nervous system, with its convulsion, its insanity, its sensory disturbances of all kinds; or to the heart, with its multitudinous vagaries of action; to the liver, with its storms, lithæmic and glycosuric; to the kidney, with its tides high and low, alkaline, albuminous—all these, and no doubt others also, may readily be made to do service to the advocacy of the importance of the *rôle* of rhythm in pathology.

But I would not hold, as some perhaps might do, that pathology is exclusively devoted to the processes of decay. It concerns itself with the dissolving view of life, and therefore is largely occupied with methods of degeneration, but by no means entirely so; for surely if we study the behaviour of many of the new growths, be they hypertrophic, inflammatory, or heteroplastic in their constitution, there is evidence in many a case, not of decay, but of unnatural vigour; and it is this that proves destructive to the organism. A particular tissue or group of cells grows in excess, and other parts necessary to the due carrying on of life atrophy because of its greed, or follow its bad example, or are involved in the anarchy of disease—infiltrated we say in pathological language. But this is all physiological; it is a physiological process, an abounding vitality, that kills us—for who will say that growth and reproduction are not natural processes? The fecundity of a people is a measure of its prosperity; is it less so with the fecundity of the cell?

Have you ever followed out this line of thought or any one of its numberless by-paths? Have you ever, for instance, studied pathological processes by approaching them from the side of the individual cell—by synthesis rather than analysis? Take, for instance, if you can, the elementary cell, and place it in your mind's eye, side by side with one of the vegetable kingdom whose physiology is so much more open to inspection. What about warmth and moisture? Growth is unquestionably favoured by such an environment in the vegetable world; has it no parallel for us? Who will say "No," when a telegram such as this was received at the Guy's Nursing Home only last week: "Please send nurse immediately, skilled in poulticing"? Now what do poultices do? So far as I could make out from inquiry in the particular case, the required skill was the ignorance that should put them on hot enough; in fact, warranted to scald well! Poultices never should be painfully hot, gentlemen. If you want a blister, put on a blister, not a poultice. But this is by the way. In mentioning poultices, too, I am reminded forcibly that our knowledge of pathology is advancing, or perhaps I ought to say changing, rapidly. Forgive me if in the light of modern surgery I speak of what should seem to antiseptics as but obsolete barbarity. But, at any rate, poultices used to be applied—and no doubt successfully so—for the purpose of encouraging suppuration, and this encouragement was in great measure due to the application of warmth and moisture, and to the promotion thereby of cell growth or proliferation. We to some extent know that this is so, for in the lowest forms of animal life a carefully graduated application of warmth can be shown to increase the activity of cell proliferation. I doubt not that you can supply illustrations from your own experience of morbid processes which illustrate this, but I may mention acute inflammatory conditions of the respiratory tract and tropical abscess of the liver as two such. In the case of acute bronchitis, for example, the last thing you would do would be to put the patient into a dry, cold room; on the contrary, you surround him with a warm, moist air, and by that means unquestionably you promote secretion, and secretion is the correlative and complement of cell growth. The case of tropical abscess is more open to dispute, but it is taught by many of the ablest of those who have practised in hot climates that acute hepatitis—and its consequence, abscess—is the fate of those chiefly who imbibe freely of alcohol. Now we know that in England alcoholism never leads to hepatic abscess. I do not wish you to suppose that the fact admits of no other interpretation, for abscess of the liver of all kinds, solitary as well as multiple, are considered by some to be the result of portal pyæmia secondary to dysenteric ulceration of the intestine; but it is a favourite idea of mine that the tropical abscess is an illustration of this forcing action upon the hepatic cells, the hot-house favouring the luxuriant cell growth of abscess, while the temperate or cold-house cultivates the hardy perpetuals that we know as cirrhosis.

And still asking your attention to the primordial cell, have you ever attempted to apply the law of variation, as it occurs in all plants and animals, to it? If its natural outcome be not tumour growth, it comes very close to it. As a matter of experience, we know that all of us are not equally liable to

Digitized by Google

develop these new growths. The tendency lies in particular strains, not as yet fully determined or understood. But my point is this: given the weakening of the restraining something, whatever that may be, which keeps the various parts of the complex organism is harmonious correlation, and by the simple laws of variation one could build up an explanation, a pathology therefore, of what still perplexes us and is likely so to do—the growth of tumours. As part of the same line of thought, too, think of the possible effect on the tissues of an excess of nutriment—a cause of monstrosities in plants, is it less so when we come to deal with the animal world? Supposing any part—take a gland cell from the breast for example—has a food supply for long in excess of its requirements, may we not have then, only supposing again some slight deficiency in the safety-valve, the first starting point of a tumour?

The question of the harmonious correlation of the various parts of the body, as necessary to the maintenance of health, is indeed a fundamental one, and numerous are the evils that may arise if the physiological balance be disturbed. One of the best illustrations perhaps of this is to be found in the curious overgrowths of fat and connective tissue that are occasionally seen in males in whom the sexual organs have failed to develop; another in the abnormal growth of hair which is sometimes associated with a similar arrest of development in females. I am myself disposed to think that the mental defect of the cretin with the associated overgrowths of fat that are present in various parts of the body are also to be explained in a like manner, notwithstanding that just now the balance of investigation seems to indicate that these things may be due to some deficiency of function on the part of the thyroid gland. But a somewhat similar change occurs in young children whose intellectual development is arrested by the growth of an encephalic tumour. All these may, I think, be in part explained by such defective correlation as I have supposed. The idea may be in part brought home to you by taking as an illustration the traffic of a great city. Supposing that the roadway of London-bridge or Regent-street is up, we all know very well the congestion that results in the tributary conduits, and if the derangement continues for any length of time the trade along the route suffers, and other thoroughfares more easy of access reap the benefit. The analogy is not perhaps of the closest, yet in it may be seen something which applies to many conditions of disease. In the case I have already quoted, I see the body furnished with what, for our present purposes, may, I think, be called a *constant* supply of pabulum. If the brain or the sexual organs, or any other part you like to mention, is working at low tides, or not at all, by some complete arrest of development, the common fund is replete with material that should have been removed, and other parts get the best of it, or worst of it, as the case may be, according as the other man's scraps are to them refuse or luxuries. Another fact of the same kind, and to my mind accepting the same explanation, is that when some large part of the body has been removed, chiefly the lower limb at the hip joint, there has been noticed a tendency in some cases to the growth of an excess of fat. Again, it is the practice with many surgeons, and unquestionably a sound one, not to do any severe operation without first having the patient quiet and in bed for some few days. Because it has been found that a preliminary treatment of this kind is more favourable to the prevention of any subsequent inflammatory processes in the wound, and therefore to the promotion of recovery. I should venture to interpret this practice after this fashion: Without the preliminary enforced rest the circulation is likely to be vigorous; the nutrient supplies abundant; the changes active. Inflammatory processes would under such conditions have from their point of view a good time of it, and probably run to excess. Whereas in the state induced by quiet and moderate nourishment the supplies are all kept well in hand, and any reactionary demonstration is deprived of its spirit by being starved of its food.

There are two other circumstances in surgery which occur to me in corroboration: one, that what are called primary amputations—that is, those done in full blood for injury—are much more dangerous than those done for disease; the other, that operations in old people often do remarkably well in respect of the local conditions. I have seen the edges of incisions for hernia in old people lie together and unite, as I have often thought, from sheer want of pluck, so to speak, to resent the injury. And if you think I am making much of very little in saying all this anent disturbances of correlation, ponder this passage from the "Autocrat of the Breakfast-table" and follow its pathological lead: "It is a good sign to have one's feet grow cold when he is writing. A great writer and speaker once told me that he often wrote with his feet in hot water; but for this all his blood would have run into his head, as the mercury sometimes withdraws into the ball of a thermometer."

Well, then, for my part I like sometimes to press this analogy between high life and low life still further, and to carry back one's idea of education and training until they converge on the rudimentary unit. May we not say that in the influence of one cell badly bred and badly trained upon the "habits of good society" (in cell life) we have another idea of the nature of that inexpressible something we call malignancy? Bad education allows of the formation of bad habits; and there are few more interesting lines of thought than that suggested by the diseases of faulty habit. Possibly I may enter more fully into this subject in another lecture. For the present purpose I will only say that a recognition of what we call "habit" is not out of place even in attempting to unravel the processes of cell life, and that, whatever be the organ or the tissue from which we take our cell, it is true—first, that stimulation leads to the exercise of function; and next, that the more frequent, short of exhaustion, the one, the more immediate becomes the response of the other, until at last a response is apparently elicited by stimuli that are quite insignificant as compared with those which called it at first into exercise.

Take two illustrations, most instructive in their differences—the nerve cell and the gland cell. The one, accustomed to action by means of discharge of nerve force, passes on in pathology through various stages of aberration into insanity. What of morbid anatomy have we there? The gland cell, on the contrary, uses up its stores of energy in the formation of fresh cells, and represents its storms by the number of these and by their form. But, as I have already said, each for each, the insanity and the secretion, or what represents it, are equivalent expressions. Surely in this lies in part an explanation of the proneness of certain tissues to grow out of bounds; of the exceeding rarity of tumours in some parts. New growths of true nerve substance (not of their cement or connective tissue) are very uncommon; and I think one might, *a priori*, from considerations of this kind have expected them so to be. For if it be true that the discharge of nerve force be the fundamental endowment of nerve cells, these must needs more readily manifest disturbance in the direction of their accustomed *habit* than in that of proliferation to which they are unaccustomed; and by the same argument the epithelial cell, knowing nothing of the tortuosities of lunacy, is liable to expend its abnormal energies in the folly of the growth of tumours. But, further, we know that what is a mere acquired habit in one generation may become by inheritance a fixed or constitutional action in another. The most direct evidence of this perhaps is supplied by some well-known experiments by Dr. Brown-Séquard upon guinea-pigs. He first made them epileptic and then paired them, and, as a result, produced an epileptic family, showing the same tendency to convulsions as their parents, although they themselves had been subjected to no lesion of any kind. It seems fair to assume, with an example of this kind before one, that there is no great improbability of the transmission of a habit when the conditions are apparently all simplified down to a most rudimentary one of the impress of a similarity of functional exercise by the parent cell on its progeny. But I take it as additional evidence that facts go to prove that in a long course of years a race of madmen or criminals may be produced. Insanity has no right to be considered in all cases as a sudden explosion, which, once happening, no one knows why, is likely to crop up again both in the individual and his offspring. Insanity is no doubt, in many cases, if we could but trace the phases of progress of individual minds, the expression of a slow process of neglect of training, just as much as any masterpiece of mental work is but the topstone of an elaborate and persistent purpose. And what more hopeful view could be taken? In the one case a man is the sport of a predestined fate; in the other he is to some extent the moulder of his own destiny. Madness, I say, is in many cases the result of the unchecked specialisation of nerve discharge along demoralising lines; a tumour is the climax in cellular pathology to a long indulgence on the part of cells in ill-assorted pairing, or what represents it in that low order of creation. The process starts in one cell,

Digitized by Google

mitted to the next, and so on, the primary variation g ever more marked. And when investigating any disease from this point of view, who can tell how nerations have passed by and left their mark? Yet ly, if it be accepted as a recognised fact that in the ction of the species there is a tendency to the formation of varieties, which by a process of natural n are liable to become permanent, we cannot refuse nowledge the existence of such a tendency in the y elements of the organism. If the whole varies, its ill vary, and then I apprehend there will probably such process amongst the cell element of our tissues may correspond to what Darwin described as the val of the fittest." The cell varies under existing ons because those local conditions have been favour-, one might well say, have compelled variation; and ult being that best adapted to the environment, sup- this to be constant, will tend to be perpetuated. It seem a strange paradox that such beggarly elements pose a malignant tumour should constitute an example survival of the fittest, yet such in a limited sense, confining ourselves strictly to a pathological aspect, ay be said to be. This may seem a fanciful idea and no practical value, but yet it may possibly help you, r by attraction or repulsion no matter, so to arrange wn thoughts as shall enable you to discern, each in own way, something of the nature of what is called ancy.

ing suggested a cognate subject, let me now deal it a little more in detail. It is an old and favourite with me that secretion and growth, in the case of may to some extent be correlated and convertible. It teresting feature, at any rate, of glandular pathology he development of tumour centres round the epoch of g into maturity, and that when the heyday of func- as passed. Furthermore, there would seem to be a cy on the part of glands that for one reason or another ever fulfilled their own longings to produce morbid ; and there is likely to be some correspondence n the rapidity of the growth and the activity of the es going on in the body or in the part at the time of elopment. Now, what is secretion? May we not e modified growth? It is yielding up of themselves part of the gland cells to the production of a highly ised material necessary to the economy, and it ly very suggestive that gland tissue, before it at this self-sacrificial stage of unconscious martyr- hould sport or revert to some less specialised pro- n. Accustomed to periodic affluxes of excess of t supplies and to equivalent discharges, when the ds cease to which these discharges answer, the un- d energy is appropriated to other ends, or rather ates the gland cells to other processes. And one may uppose that this will be still more the case when, n energy and potentiality for a still higher develop- they have never been taxed at all. It is thus, to my that we have the cancer of the mammary gland in ale never pregnant or after childbearing has ceased, ioma of the undescended testis, the soft and rapidly ers of childhood, the hard and withered cancers ery old.

another aspect of my subject—viz., the influence of in determining disease—and see how it leads round this same goal as that we have already arrived at. In me by—gone by, did I say? I had rather said to the judgment of age—the innate tendencies of the indi- the constitution," to adopt the popular term, seemed worth attention. The impulsiveness of youth localise everything, for by that means chiefly victory be won. But do not forget that the which gains the end, while averting the less conspicuous, is the greater feat of train- You may sometimes hear it said of your- "Dr. A. is very clever, but he is so old Mr. B.; he knows my constitution." is unlettered, perhaps, but it is sound just now I would press home not the the importance of the consideration diseases there is a local factor concerned in the building up of any ular affection. I will take a syphilis to begin with.

son gets out of this difficulty by suggesting that, originally an all-pervading disease, it ceases to be so after a time, but that relics remain in this part and in that, and that these local germs may prove troublesome years after the original malady has subsided. Recent observations, which go to prove syphilis to be a germ disease, have, I think, done something to render this hypothesis a probable one. Moreover, there is a somewhat similar sequence of changes in typhoid fever, where certain local inflammatory formations are liable to appear during convalescence. But there is another explanation which I prefer, and it is this: Once syphilised, alway so; at any rate, so long as late evidences of it show themselves. It is precisely on all fours in this respect with scarlatina and variola. In any one of them you may have the disease a second time, but if you do, *you* are the peculiarity, not the disorder. We do not know what happens, but we say that these diseases as a rule exhaust the soil, and all the tissues thenceforward are bred up to the altered standard. But the alteration is invisible with scarlatina and variola, and there is an end of the matter. But syphilis is peculiar—its type is the invisible portrait—breathe on it and out comes the donkey. If a man has had syphilis and he happens to be your enemy, and you, although a doctor, be sufficiently political to be adequately lost to everything but your own ends, advise him to take a six months' course of hard training and aquatics, and he will probably come back to you with an aneurysm of the aorta; or bid him live freely both in eating and drinking, and he will worry his liver into what is called gummatous cirrhosis. A judicious kick at football may land him in a periostitis of his tibia, and so on. Forgive the flippancy, but I want to drive home this thought, that syphilitic inflammations do not burst out haphazard, but that when we find the cellular membranous sore below the patella, the gumma in the testis, the aneurysm of the aorta, the thrombus in the brain, these things come to such parts as receive injury, or are overworked, or are stimulated to resentment by some persistent irritation such as alcohol is to the liver. A beautiful illustration of this occurred in a case that I admitted a year or so ago, in a man with a much enlarged liver. He died soon after his admission, and Dr. Pitt, on making the post-mortem examination, found a huge gumma in the liver, and in its centre an old hydatid. There could be no question that the hydatid had provoked the gumma. You cannot, it is true, always put your finger on the exciting cause. The "why" of a gumma in the brain is a very difficult question to answer to the satisfaction of one who will not go further than he can see. Nevertheless, I will not lose the opportunity of insisting that this local provocative is a most important item in the pathology of late syphilis, and this is corroborated by Sir James Paget's statement that late syphilis is infrequent amongst the upper classes. This means, I take it, that in the well-cared-for, the well-to-do, the free from worry, in those who lead less laborious lives, &c., the local factor is reduced to a minimum. Thus I would say that, when a man has had syphilis, pathology teaches that he should go softly. He has in a measure used up early the margin of the vital capacity of his tissues, that margin which endows man with his ever bubbling energy, which gives him the true pleasure of living. He must pay the penalty, and live henceforth a more confined existence; he must live by rule, and haply thereby he may still live a useful life. If not, he must take the risk; excess will shrivel his skin, will bleach his hair, will dull his brain, will further the processes of disintegration which the initial energy of his being has now no longer the power to stop, and by insidious paths the eye cannot trace will send him back to dust a wasted life.

But this is rather diverging from the main question now before us, so let us take the case of the aorta—indeed, of all the vessels; their pathology is the outcome of their position. I have often said before that there would be but little atheroma of the arch of the aorta if it ran in a casing of plaster-of-Paris. The diseases of arteries are due in the main to the wear and tear to which they are subjected, and if you study the anatomical arrangement of the vessels you will be able to say what are the points on their route most open to aneurysm. It is the main trunk of the aorta which suffers most, and the arch, which bears the brunt of the impact of the blood, most of all. But the occurrence of aneurysm on smaller vessels is not less instructive, for it occurs at the coeliac axis, in the popliteal space, in the groin, &c., all of them points where either the stream splits, or the move- subject the vessel more than elsewhere to.

Digitized by Google

chances of injury or friction. There are, besides, atheromatous vessels elsewhere far too instructive to be passed over: there are those of the brain. Once more let the Autocrat point you to a pathology: "The men of genius that I fancy most," says he, "have erectile heads like the cobra-di-capello. You remember what they tell of William Pinkney, the great pleader; how in his eloquent paroxysms the veins of his neck would swell, and his face flush and his eyes glitter, until he seemed on the verge of apoplexy. The hydraulic arrangements for supplying the brain with blood are only second in importance to its own organisation." And I would add, when we consider its own organisation in a more anatomical sense than the author alludes to, that it and they together explain the frequency of apoplexy. The advantages of the one entail the risks of the other. Take, again, the vessels in the lung. No one would require to be instructed in the cause of hæmoptysis when he can see for himself in the post-mortem room that it is nearly always due to the existence of a cavity in the lung and to a bulging of a vessel in its wall, which has lost its support and become diseased. And once more: atheroma of the pulmonary artery but seldom occurs, and when it does it is always in association with some pulmonary stasis which has necessitated undue distension, and therefore strain, of the affected vessels.

I dwelt last year upon the meaning of the spread of phthisis in the lungs—how largely it depended upon the disadvantages of locality. I shall by and by have to say something upon the importance of the same line of thought in considering the morbid anatomy of the stomach and intestines. I shall, however, only say now, and as carrying us back to our earlier contention, that there are numberless instances in these regions, of disease originating in parts that, altogether on *a priori* grounds, one could say are likely to become diseased. Further, there is a considerable amount of evidence to show that in some of these there is a life history of cell growth such as I have attempted to sketch—a passage apparently of simple healthy toned cells, by various stages, into malignant cells. Time fails ere I have supported this hypothesis by appealing to definite lesions. I had intended to take a form of disease of the tongue which may be called simple hypertrophy, and another, a chronic ulceration of the tongue, and from their common goal in cancer to fill in the gaps left by the defects of the pathological record in a scheme of malignancy such as this: that healthy physiological type is constantly owning departures in small degrees; that these variations, if the cause of departure continue, not only become persistent, but generation after generation (in cell life) much more pronounced, until at last a time comes when the family likeness is altogether lost. I cannot put it better than I did some years ago, in Dr. Maudsley's words, "that the criminal class constitutes a degenerate or morbid variety of mankind. They are, it has been said, as distinctly marked off from the honest and well-bred operatives as black-faced sheep are from other breeds, so that an experienced detective officer or prison official could pick them out from any promiscuous assembly at church or market. They herd together in our cities in a thieves' quarter, giving themselves up to intemperance, rioting, and debauchery, without regard to marriage ties or the bars of consanguinity, and propagating a criminal population of degenerate beings." Is not this the life history of a cancer? Aided by the light of such morbid sequences as I have mentioned, we can see first the gradual formation of an atypical race of cells, and next a succession, ever becoming more renegade, until at last the ties which bind them to the tissue are discarded altogether—they have denied (amongst cells) their social obligations, to live the short life and the merry one of the profligate.

I started by saying that pathology is the natural complement of physiology, and to that end have been endeavouring to depict by means of familiar analogy the life history of a single cell as it may be supposed to run, on one of the highways of pathology, from the cradle to the grave. But pathology is far reaching in its embrace, and a cellular pathology such as this, however attractive, is no more than a small part of the extent of the study. To be able to explain even such a limited part of it as we have to-day concerned ourselves with, you will require to know something of embryology and of comparative anatomy and pathology. There are tumours which, having regard both to their position and their structure, can only be explained by a knowledge of these. Another large branch of pathology, which in the present day is assuming the most bewildering proportions, depends upon a knowledge of the life history and behaviour in the tissues of parasites. And yet again there is the most fertile and inexhaustible field of physiological and pathological chemistry waiting for workers, and far too little heeded by the morbid anatomist.

But I must draw to a close. Let me say of the subject in general before I end that instruction is in the main conducted on one or other of two lines—the suggestive or the dogmatic. Pathology as I have put it before you to-day is the one; morbid anatomy fundamentally the other. But no rule is absolute, and both these assertions require important qualifications. It would be a sorry climax to this morning's labour, yours and mine, were you to go away with the idea that the one was interesting, no doubt, but highly speculative and unpractical; the other a string of dead facts with little to enliven them. This, unfortunately, is the thought of many who have paid no attention to the subject. And it is a criticism on morbid anatomy that you will often hear that it gives you no aid in treatment. Supposing that this were literally true in the sense that is meant, I would still not admit for an instant that its study were valueless, for study what you like, so long as you do study it, any investigation is instinct with instruction in all manner of ways that the ignorant man never dreams of. It is thus particularly with histology. There is certainly no very evident relationship between the study of histology and the treatment of disease, yet I shall make bold to say, as a matter of personal experience, that it will offer you hints and suggestions in this respect that one would not conceive to be possible until one had experienced them. It is, indeed, impossible that you should give thought to any morbid change and acquire knowledge concerning the actual conditions that exist, without acquiring also some ideas which concern themselves with its treatment. Be they but few, they must at any rate be more than that man possesses who has not a notion, or an entirely imaginative one, of the changes that have passed or are passing. The point would not be worth argument were it not that those are wont to make much of it who for every disease and every symptom vaunt their knowledge of a drug wherewith to scotch it. Let me, then, say to you, with all the earnestness of the most complete conviction, that while the neglect of the study of morbid anatomy and pathology tends dangerously towards the exhibition of temerity when there is need for caution, of hesitation when one should be bold, of quackery in place of the line of light and leading which it is ever our highest function to assert, the knowledge of it will make you not only exact, but skilful and ready, as good pilots amid the shifting quicksands of disease.

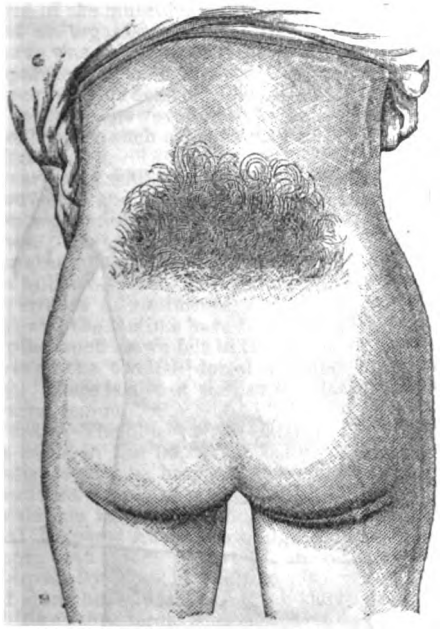
ABSTRACT OF A

Clinical Lecture

ON

SPINA BIFIDA OCCULTA, AND ITS RELATION TO ULCUS PERFORANS AND PES VARUS.

BY J. BLAND SUTTON, F.R.C.S.,
ASSISTANT-SURGEON TO THE MIDDLESEX HOSPITAL.



GENTLEMEN,—The term "spina bifida occulta" is applied to a defect in the arches of the vertebræ, such as occurs in the commoner forms of spina bifida, but no tumour or cyst appears externally. The deformity is, however, accompanied by some remarkable external conditions and complications, which are interesting from many points of view. For the term "spina bifida occulta" we are indebted to Virchow; the history of the matter runs somewhat as follows:—

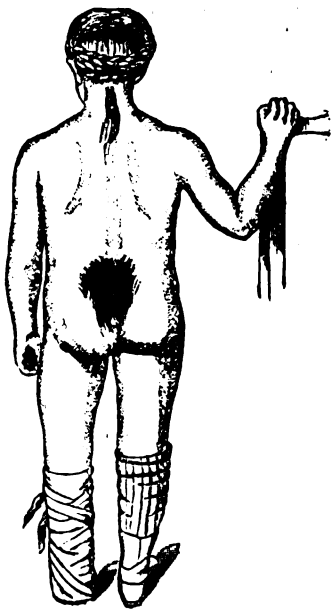
In the year 1875 Dr. Bernhard Ornstein of Athens communicated to the *Berliner Gesellschaft für Anthropologie* an account, with a photograph, of a Greek soldier whose loins presented an abundant crop of long hairs. The hairy growth occupied the middle line of the back, and extended thence on each side. The hairs were so long, that the man found it necessary periodically to cut them, in order to prevent interference with defecation.

Digitized by Google

A few months later, before the same Society, Virchow, referring to that very curious phenomenon, or law of duplicity of cases, stated that on the morning when he received the letter from Athens regarding Ornstein's case, there was a subject in the pathological institute which presented an unusual hairiness of the back. It was the body of a woman, aged twenty-four years, who died from peritonitis after typhoid fever. The position of the hairy spot, and its general shape and appearance, may be gathered from Fig. 1. The patch measured ten centimetres in diameter, and the hairs, which were blonde, measured from six to seven centimetres in length. The skin at this spot appeared normal. A closer examination of the part revealed the following important facts. The hairy patch corresponded to a depression which could be felt in the spine, and on removing the skin a spina bifida occulta was discovered. The spinous processes of the upper sacral vertebræ were replaced by membrane. The arches of the four lower lumbar vertebræ were incomplete, thus giving rise to a fissure, which was filled by a kind of fibro-cartilage. Virchow[1] further expresses the opinion that this collection of hairs differs from moles in ordinary, and ought to be regarded as the result of

FIG. 1.

A case of spina bifida occulta. (After Virchow.)



local irritation, due to disturbance during the development of the spinal column.

The next case was published in the *Deutsche Zeitschrift für Chirurgie* (Bd. xvii., p. 1), by Fischer of Strasburg. It occurred in a girl aged nine years and a half. This child, as will be seen from Fig. 2, presented in the loin a hairy patch of irregular shape. The hair was of a brown colour, and varied from five centimetres to fourteen centimetres in length. The skin from which the locks grew was normal in colour and thickness. The eye, however, detected an abnormal depression of the spine in this spot. Manipulation revealed the fact that the spinous processes of the second and third lumbar vertebræ were curved, and deviated from the middle line. The spinous process of the fifth could not be felt, and the finger detected a fossa in this situation. At the angle of the scapula there was a small dark-brown but hairless pigment spot, and a similar one existed to the right side of the spine a little above the hair-field. In the neck, between the third and fourth cervical vertebræ, was a lock of long hair (seventeen centimetres), the skin was normal, and the vertebræ in this situation did not present anything pathological. The girl also suffered from chronic ostitis of the metatarsal bones of the left foot, which was also in a more or less anæsthetic condition. To remedy this, Chopart's amputation was performed. The foot was examined and reported upon by Recklinghausen. The report is published at length

[1] Zeitschrift für Ethnologie, 1875; and Berlin Klin. Woch., 1884, p. 747.

in Fischer's paper. The most noteworthy change was found in the arteries. Their walls were hypertrophied, especially the muscular layer. There was endarteritis and an obliterating thrombus in the main trunk of the plantar artery. This last complication is of some importance in connexion with the remarkable case now to be mentioned.

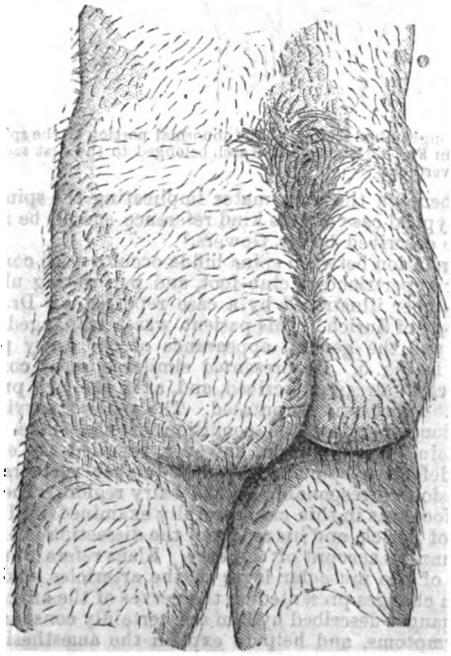


FIG. 2.

A girl with spina bifida occulta in the lumbar region, accompanied with hypertrichosis. There is also a lock of hair in the cervical region. There was also ostitis of the metatarsal bones of the left foot. (After Fischer.)

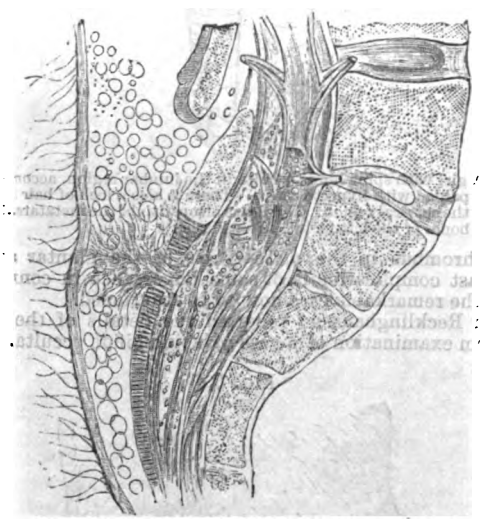
Von Recklinghausen[2] reported the details of the post-mortem examination of a case of spina bifida occulta. The

FIG. 3.

Abnormal hairiness of the loins, due to the irritation of a spina bifida occulta. (After Recklinghausen.)

report is accompanied by a careful description of all the parts concerned. There was marked lumbar hypertrichosis, as shown in Fig. 3; and, in addition, the patient, a man aged

[2] Virchow's Archiv, Bd. cvi., 1886; and Untersuchungen über die Spina Bifida. Berlin, 1886.



Digitized by Google

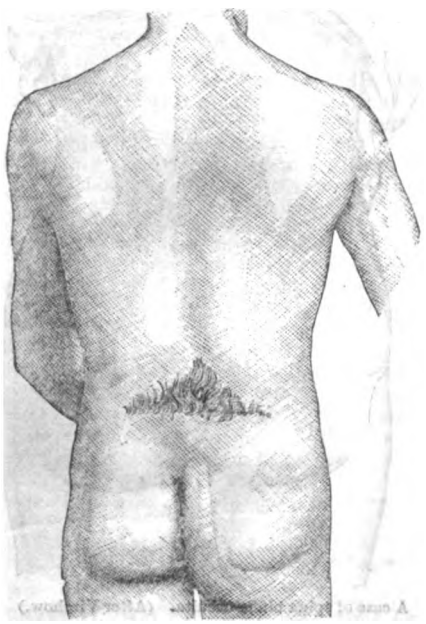
twenty-five years, suffered from club-foot and a neurotic ulcer (mal-perforans) of the left foot, accompanied with anæsthesia. For this trouble amputation was performed by Fischer, but the man only survived the operation a few days.

At the post-mortem examination it was found, on bisecting the spine, that the cord extended lower in the canal than usual. Instead of terminating at the second lumbar, it ended at the second *sacral* vertebra. Lying in the canal, between the fifth lumbar and first sacral vertebræ, was a lipoma. It was situated within the dura mater, but communicated by means of a rounded orifice with the general tissue of the lumbar region, as represented in Fig. 4. On microscopical examination this tumour was found to be composed of fat and striated muscle fibres. The individual fasciculi strongly resembled the arrangement found in the multifidus spinæ muscle. In this instance, as in the preceding case, Recklinghausen found no changes in the nerves of the foot on microscopical examination; but there was hypertrophy of the muscular layer of the arteries, visible in the cut sections of the tissues of the foot in the immediate neighbourhood of the ulceration; the intima was normal.

Perhaps one may here digress, and draw attention to the valuable light such a case as this throws upon those tumours, composed of fat and striated muscle fibre, which have been

FIG. 4.

Longitudinal section of the abnormal portion of the spine in Fig. 3. The defective arch belonged to the first sacral vertebra.



found beneath the dura mater implicating the spinal cord. For a typical case of this kind reference should be made to the one described by Dr. Gowers.[3]

The relation between spina bifida occulta with congenital lumbar hypertrichosis, club-foot, and perforating ulcer, has been further illustrated by a case reported by Dr. Conrad Brunner[4] of Zurich. This patient was a man, aged twenty years, and the general appearance of the hairy patch is shown in Fig. 5. He presented similar clinical conditions to the cases already described, and, as in the two preceding ones, the foot was amputated. The patient survived the operation, therefore the condition of the spine remains uncertain. Manipulation, however, revealed the existence of a defective spine to the first lumbar vertebra, and a depression corresponding to the hairy region. The amputated foot was in this case carefully examined by Professor Klebs of Zurich, and his report of the dissection is embodied in Brunner's account of the case. Klebs refers to a hyperplasia of the muscular layer of the arterioles, and details certain changes presented by the nerves of the affected foot. The changes described by him are certainly consonant with the symptoms, and help to explain the anæsthesia which was observed in the foot.

As far as my knowledge of the literature extends, the preceding are the four most important cases that have been recorded; the remainder were detected in fœtuses, and are described in Recklinghausen's memoir before quoted. My attention was first directed to this matter when engaged recently in studying spina bifida, but more especially on account of the subtle inferences of Virchow, when he uses these cases to explain the tuft of feathers on the head of the Polish fowl and the underlying cranial defect, as of the nature of a transmitted pathological condition, the tuft of feathers being analogous to the growth of hairs in the loins in spina bifida occulta. The conditions are alluded to and illustrated in THE LANCET of Feb. 26th, 1887. I have for some time been on the watch, and have examined many patients with the hope of detecting one of these cases. At last, through the kindness and courtesy of Mr. George Lawson, I have been enabled to study one of these interesting patients.

Three years ago Elizabeth ——, aged fifteen years, was admitted into the Middlesex Hospital under the care of Mr. George Lawson, suffering from an ulcer on the sole of the foot and caries of the metatarsal bones. At that time the patient stated that she had always suffered from cold feet, and regarded the ulcer as a chilblain, which had existed for several years. The foot was removed at the ankle joint by Mr. Lawson after Syme's method, and the girl made a good recovery. The case at the time struck me as being peculiar, and I subsequently made a careful dissection of the foot.

FIG. 5.

Lumbar hypertrichosis associated with spina bifida occulta. (After Brunner.)

Compared with its healthy companion it had a stunted appearance, and presented a minor degree of varus. The toes were short and stumpy, and at the ball of the foot was a circular ulcer with thick and callous edges. At its base a fistula was found which led to a carious metatarsal bone. All the tarsal and metatarsal bones were full of semi-fluid fat, their compact tissue being exceedingly thin. I heard no more of the girl until May, 1887, when she was brought into the operating theatre for reamputation of the stump. The base of the stump presented an ulcer of the size of a crown piece, and about a quarter of an inch in depth; the edges were callous and suggested to those who had charge of the case ulceration from pressure. Being fresh from the study of spina bifida, the whole history of the case was suggestive of spina bifida occulta, and in company with Mr. Browne, the house surgeon in charge of the case, I made a critical examination of the girl's spine. This is what we found: On the right side of the loin is a deeply pigmented wart. On counting the spinous processes of the vertebræ downwards, they all follow regularly until the lumbar region is reached; then they deviate to the right side. Instead of prominent spines, the finger feels a flattened but fairly firm tissue until the third or fourth lumbar arch is felt; at this spot an irregularly rounded depression covered with mem-

[4] Virchow's Archiv, Bd. cviii., S. 494.

Digitized by Google

brane is detected. Upon pressing this the girl evinces signs of pain and resents the manipulation. On asking the patient to bend forward, we found that the loin remained quite flat, and did not present the ridge, or prominent row, of spinous processes normally seen in this part of the back. Further, on glancing laterally across the loin the eye at once detected an abundant crop of fine downy hairs, radiating from the soft point in the vertebra as from a centre. These downy hairs are not conspicuous unless carefully looked for; they resemble the fine lanugo-like hair seen around the outer edge of a meningo-myelocele in an infant. From these facts it is clear that the ulcer of the foot, the varus, the condition of the metatarsals, and the ulceration of the stump must be attributed to the malformation of the spine; and that this girl has a spina bifida occulta which differs from the preceding cases only in the fact that the hairs are small, colourless, and inconspicuous, instead of being long and coloured. We must now consider the condition of the stump. The appearance of the ulcer on the apex of the stump has been already described, and need not further detain us. Portions of the anterior and posterior tibial nerves, arteries, and veins were removed as near as possible to their terminations, without spoiling the stump for museum purposes. The arteries displayed, as Recklinghausen has described, a marked increase in the size of the muscular layer. The posterior tibial veins exhibited an organised parietal thrombus. The posterior tibial nerve was the seat of extensive change. The fasciculi were separated by collections of fat, and in no part was healthy nerve tissue detected. The examination of the stump in this instance, however, can be only of secondary importance, because such changes may arise independently of any central lesion.

Six years ago, whilst preparing the spinal column of a child two years and a half old for teaching purposes, my attention was arrested by a curious deficiency of some of the arches. The specimen was preserved for future study. A re-examination of the specimen shows it to be an example of spina bifida occulta. The spinous process of the tenth dorsal vertebra is rudimentary, that of the eleventh is wanting, and the laminæ have failed to unite, leaving a gap in the spine, such as we felt in the spine of Elizabeth ——. The spine of the twelfth dorsal and first lumbar are rudimentary. There is also a similar but larger defect in the upper sacral region.

Conclusion.—The object of this lecture is to draw attention to these cases, in the hope that before long many more of these patients will be brought under observation. With a more abundant supply of material of this character we shall obtain valuable information regarding central disturbance and local lesions. Such knowledge as this is becoming daily more and more important, in relation to visceral nerves, especially those relating to vaso-motor fibres. The study of spina bifida occulta further shows that "mal perforans," like the term "locomotor ataxy," conveys no definite pathology, but serves as a convenient clinical expression for a set of associated symptoms.

REMARKS UPON A CASE OF CEREBRAL ABSCESS, FOLLOWING EMPYEMA, IN WHICH THE ATTEMPT TO TREAT BY OPERATION WAS UNSUCCESSFUL.

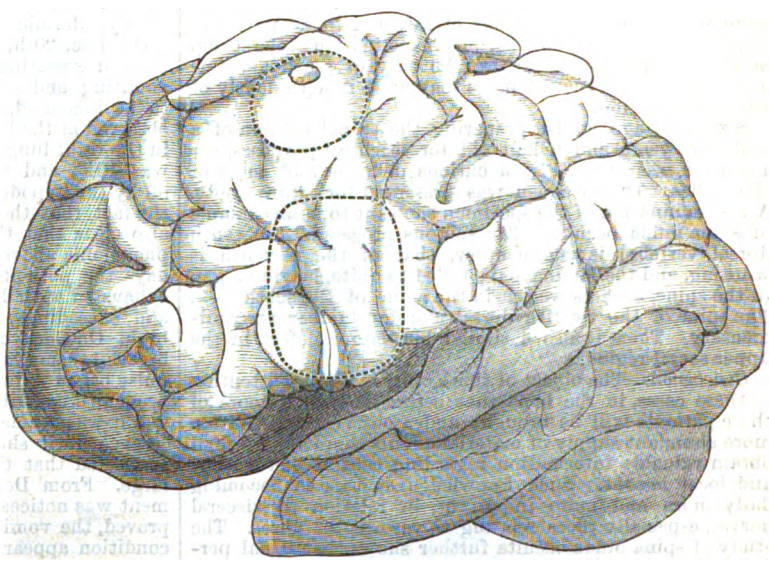
By DAVID DRUMMOND, M.A., M.D.,
PHYSICIAN TO THE NEWCASTLE-ON-TYNE INFIRMARY, ETC.

At a time when an unusual or novel, and especially a serious and momentous, method of treatment is on its trial, it is, I think, quite as important to place on record the unsuccessful as the successful efforts. Or I would go further and say that we owe it to the profession to make known the difficulties that may be found to beset a procedure not yet fully established, or, at least, not very often adopted. Of late the subject of brain surgery has been brought prominently forward by Hughlings Jackson, Hughes Bennett, Godlee, Victor Horsley, Gowers, Hulke, Macewen, Barker, Greenfield, and others, and the fact has been clearly demonstrated that sound surgical principles are just as applicable to the cerebrum as to any other organ. It is clear, however, that medicine and surgery must go hand in hand, as the site of the lesion must be fixed before it can be dealt with, and one of my objects in publishing the following case is to point out the difficulty and disappointment that may attend such an attempt.

M. T——, aged twenty-nine, a widow with two children, and by occupation a laundress, was admitted into the Newcastle Infirmary on Dec. 18th, 1886, complaining of pain in the left side of the chest and shortness of breath. She stated that her attack, which was ushered in by shivering, was of two weeks' duration. The only piece of information of any importance bearing on her family history was the fact that one sister had died of phthisis. Her own previous record showed typhus fever when a girl, lead-poisoning four years before her admission, when she was employed at a white-lead factory, and hard work with much exposure as a laundress for the past two years—i.e., since the death of her husband.

State on admission.—The patient was anæmic. The respirations were short and quick, 40 in the minute; the pulse was 120, soft and easily compressible; and the temperature was 100·4°. The tongue was coated. She complained of pain, of the ordinary pleuritic character, in the left axillary line, about the fifth and sixth ribs. The physical signs of effusion in the left pleural cavity were present—impaired movement, vocal resonance at base diminished, dulness absolute from angle of scapula downwards, distant sighing, tubular breathing, and so forth. The effusion, as shown by the hypodermic needle, was clear.

On Dec. 20th, two days after admission, a rigor with marked sweating occurred, the face became flushed, and vomiting and diarrhœa set in. The dulness was found to be increased, and well-marked Skodaic resonance was observed at the left apex, whilst coarse râles were audible in the right lung and upper part of left. The temperature was 104°, and the pulse 130. Next day pus was drawn off by the hypodermic needle from the left base, revealing the fact that the case was now one of empyema. It was also clear that the left lung was in a state of croupous pneumonia above the fluid at the back. For the next few days the patient's condition was most critical. She was exhausted with diarrhœa and vomiting, the pulse was 140 and exceedingly weak, whilst the temperature remained high. On Christmas Day it was feared she was sinking; the breath became excessively foul, she lost her voice, and the pulse began to fail. It was evident that pneumonia with bronchitis contributed largely to this unfavourable condition, and it was deemed unwise to attempt any operative interference until she rallied, especially as the physical signs suggested that the collection of pus at the base was not large. From Dec. 26th to Jan. 4th, 1887, distinct improvement was noticeable: the temperature sank, the pulse improved, the vomiting and diarrhœa ceased, and the general condition appeared to be much better. On the latter day, however, rigors and vomiting returned, the temperature rose to 103°, and the signs of a fresh pneumonia were detected. The symptoms again subsided, and by Jan. 10th her state was so far improved that it was decided to drain the pleural cavity. Consequently she was placed under chloroform, and an incision was made by Mr. Waldy in the eighth interspace, adjacent to the angle of the left scapula. Pus escaped and a drainage tube was inserted. The dressings employed were iodoform wool and carbolic gauze. The operation was done under the spray. Next day the discharge was fetid, and consequently the cavity was washed out with weak Condy. In a few days the pus became aseptic, when the injections were discontinued. The temperature gradually went down and the pulse and general condition improved. On Feb. 11th a rigor occurred, and once more the signs of pneumonia appeared, but this time in the left apex. The temperature rose to 104° and the pulse to 130. In spite of this the discharge continued sweet and the quantity remained small. In a week this attack subsided, and on Feb. 18th the drainage-tube was removed, as it was apparent that the little pus that escaped was from the tract in the chest wall. For ten days the progress of the case was most satisfactory, but on Feb. 28th there was a rigor followed by sweating, and the temperature, which had fallen to normal, went up to 103·5°. No physical signs of inflammation could be discovered in the chest, and for a time the cause of the disturbance was doubtful. On March 3rd, the temperature having again fallen, three fits occurred, but no accurate account of their nature could be procured. Then for three days nothing worth recording happened, but



Digitized by Google

on the 6th three more fits took place, and on the 8th there were two fits. The patient now complained of headache, which she said was most severe on the left side of the head, in the parietal region. On ophthalmoscopic examination both discs were seen to be blurred and the retinal veins distended—early optic neuritis. On the 9th two fits occurred at 8 o'clock in the morning. At 4.30 the convulsions returned and continued for some time. They were now watched for two hours by Mr. Waldy, who gave the following account of the attacks: 1st, twitching of the right eyelids; 2nd, conjugate deviation of the eyes to the right, followed immediately by the head; 3rd, twitching of the nostrils; 4th, drawing up of the right angle of the mouth (limbs flaccid); 5th, rigidity and spasm of the right arm; 6th, rigidity and spasm of the right leg; 7th, the left side of the face and the left limbs then became rigid and were affected with spasm; 8th, the whole body convulsed. Consciousness was lost during these fits, ten of which occurred one after another. The pupils were widely dilated and insensible to light. The tongue was not bitten. Occasionally urine and fæces were passed in a convulsion. After these ten fits there was an interval of two or three hours, and during this time there was conjugate deviation of the eyes and head to the left, and the right arm and leg were observed to be flaccid and paralysed, whilst the left limbs were rigid and resisted passive movements. Consciousness returned to a certain extent, but the patient was distinctly aphasic, and though she appeared to recognise what was said to her, was unable to reply to questions. After this one or two more slight convulsions occurred, and, as far as they went, were repetitions of the previous fits; indeed the march of the convulsions was reproduced in a most constant and regular way. Though the temperature had fallen and remained about 99° during the previous few days, it was feared that an abscess had formed in the brain, and, as the convulsions pointed to the left motor area, it was decided to trephine in this region.

Operation (performed by Mr. Waldy).—The head was shaved and washed with turpentine and carbolic lotion (1 in 20). A quarter of a grain of morphia was administered hypodermically, and chloroform was employed as the anæsthetic. The fissure of Rolando was then marked out, the upper limit of which was taken to be half an inch posterior to the centre of a line connecting the root of the nose with the occipital protuberance, whilst the lower limit was fixed at a point half an inch above the posterior extremity of a horizontal line drawn two inches and a quarter from the external angular process of the frontal bone. A semilunar incision was now made, and a flap dissected downwards, so as to expose the skull, corresponding with the lower half of the fissure. A circle of bone was then removed in the usual way over the lower end of the ascending frontal convolution, a second circle was removed an inch higher up, and the intervening bridge of bone was sawn out by Hey's saw. At the upper part of the aperture thus made the dura mater appeared to bulge rather prominently, and at this point a hypodermic needle was introduced into the brain, but only red serum was drawn off. A branch of the middle meningeal artery was now ligatured in two places and divided, and the dura mater was incised and reflected back so as to expose the arachnoid. This membrane bulged distinctly at the lower part of the wound, being pressed out by subarachnoid effusion; here, also, the hypodermic needle was introduced and serum drawn off as before. The piæ were evidently much congested, and this was most noticeable in the neighbourhood of the effusion. A third circle was now removed just in front of the lower part of the bony aperture, exposing the posterior part of the inferior frontal convolution; but, with the exception of the subarachnoid effusion, nothing abnormal was seen. In three different situations the needle of the hypodermic syringe was introduced, but no pus cavity was tapped. The arachnoid was incised, when a considerable quantity of serum escaped. The dura mater was now stitched with a continuous catgut suture, the lower part of the wound being left open for drainage. Two drainage tubes were introduced beneath the dura, one at each lower corner, and the wound was washed with a solution of perchloride of mercury (1 in 200). Carbolised dressings were employed, and the whole operation was done under the spray. The moderate amount of bleeding that occurred from the surface of the brain was easily controlled by the pressure of a sponge.

On March 10th, a day after the operation, the patient was conscious, was able to speak, and there was no paralysis. The temperature was 99°, and the pulse 120. A large quantity of red serum was found on the dressings. There was no tension of the wound.—11th: Temperature 98·8°; pulse 120; able to speak; no paralysis.—12th: Temperature 101°; pulse 140. Patient delirious. Wound dressed, and again a free discharge of serum; no tension; drainage tubes shortened.—13th: Temperature 102°; pulse 130. Delirious and noisy; wound nearly healed; no pus; discharge quite sweet; no tension; the posterior tube removed.—14th: Observation the same.—15th: Temperature 103°. Able to speak; walked about in her delirium, which was less violent; no paralysis; wound healed.—17th: Delirious and unconscious.—18th: Temperature 105°; pulse 140. Still delirious.—19th: Temperature 107° at 6.30 A.M. Death at 10 A.M.

Post-mortem examination.—Slight œdema of the lower extremities; body somewhat emaciated; rigor mortis present.

The wound above the left ear was healed, and on tearing open the flap a small patch of purulent lymph was found on the under surface. The opening thus exposed in the skull was two inches and three-quarters long, and an inch and a quarter wide at the widest—that is, the lowest—part. On raising the skull-cap and dura mater and exposing the brain, two or three small patches of yellow lymph were found on the surface of each hemisphere, but there was nothing like diffuse meningitis. The aperture in the skull made at the operation corresponded with the lower third of the ascending frontal convolution, the adjacent part of the ascending parietal, and the posterior fourth of the inferior frontal. At the lower part of the ascending frontal convolution the pia mater was a little thickened and adherent, but no pus was seen. The posterior part of the middle frontal, where it joins with the ascending frontal, stood out prominently, and appeared to be about three times the size of the normal convolution. The pia mater was adherent to the upper part of the swelling, and an attempt to remove it tore the cortex and allowed pus to escape. A section through this portion of the middle frontal convolution revealed an abscess the size of a large hazel-nut, containing thick greenish pus. This abscess cavity approached the surface at its upper part, where a thin layer of grey matter separated the pus from the pia mater, but from this point it passed downwards and inwards, and at the middle of the prominence was nearly three-quarters of an inch from the surface. Surrounding the abscess was

Digitized by Google

an area of soft œdematous brain matter. The lower half of the left pleural cavity was obliterated, but there was not the slightest trace of a pus cavity, and the pleura was not materially thickened. Some congestion of the lung was detected, but the right was in the same condition. The remaining organs were healthy. (See Engraving.)

A more satisfactory result in a case of empyema could not well be obtained, and a more disappointing termination to a case of abscess of the brain could scarcely be conceived, for, as a glance at the accompanying drawing (taken from the brain as it lay on the post-mortem table by Mr. C. Steenberg) will show, the upper limit of the aperture in the skull made by Mr. Waldy's trephine was very close to the level of the lower part of the abscess. I was led to expose and explore the lower part of the ascending frontal convolution and the posterior extremity of the inferior frontal on account of the early implication, in the course of the convulsions, of the muscles of the mouth and right arm and leg. I fear that I under-estimated the importance of the phenomena at the commencement of the fits—viz., the twitching of the eyelids and the deviation of the eyes and head to the right; and this I was led to do because of the frequency with which the spasm in ordinary non-organic epilepsy commences with deviation of the eyes and head to one side, a fact with which all are familiar. But the condition of the patient after the fits ceased also aided in determining the site of exploration. It will be recollected that the post-epileptic phenomena were conjugate deviation of the eyes and head towards the left side (side of lesion), aphasia (even after consciousness had in a great measure returned), and paralysis of the right limbs, especially the arm. Here, again, the conjugate deviation was neglected, as we are unable to attach any localising importance to it in ordinary hemiplegic attacks, and hence my impression that the lesion would be found in the neighbourhood of the arm, mouth, and speech (?) centres, or, in other words, in the lower half of the ascending frontal and the posterior part of the inferior frontal convolutions, or at least about the lower part of the fissure of Rolando. The error of this conclusion was made sufficiently obvious at the post-mortem, for, as will be seen, the abscess was really situated in the posterior part of the middle frontal convolution—the centre for lateral movements of the head and eyes (Ferrier). I need scarcely point out that in the case before us the attempt to diagnose the position of the lesion was made at a time when accuracy could in no wise be assured; for all acquainted with the subject of localisation of brain mischief are aware that, on the one hand, paralysis is infinitely more reliable than spasm, and, on the other, that indirect symptoms often complicate the question for a considerable time, and until they pass off it is impossible to attain a high degree of likeliness in our local diagnosis. And, again, it will, I think, be conceded that the conditions of the post-epileptic state, no matter how well marked, are not sufficiently reliable upon which to found a diagnosis. The abscess in this case must, I think, be regarded as embolic, and I am inclined to the view that the infarct occurred some time before the rigor of Jan. 18th. It is interesting to note that the fits ceased after the operation, and that all paralysis passed off and speech returned. It is obvious from this that tension played an important part in producing the convulsions. In future, when the existence of an abscess is suspected, I should be disposed to explore more extensively, for though it was quite possible for pus to find its way out through the opening made, the chances of it so doing are nevertheless too slender to be trusted to, and the risk, from a surgical point of view, would not appear to be much increased by extending the aperture.

Newcastle-on-Tyne.

MARINE BIOLOGY. — The third annual general meeting of the Marine Biological Association was held on the 24th ult. at Burlington House, the chair being taken by Professor Flower. The report for the past year stated that the attention of the Council had been chiefly devoted to the superintendence and fitting of the laboratory at Plymouth, and to making arrangements for the future work of the Association in connexion with that laboratory, which it is expected will be ready for partial occupation in the present summer. It has been decided to issue to the members of the Association, in the form of a journal, the annual reports of the Council and other information.

ON THE FUNCTIONS OF THE FOURTH PAIR OF NERVES.

By HENRY LEE,

CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

THE fourth pair of nerves are distributed exclusively to the superior oblique muscles. They communicate with the third pair of nerves, and with the sympathetic in the cavernous sinuses. At their origin they decussate.[1] These relations indicate that they may act in sympathy with each other, conjointly, or in combination with the third pair of nerves. In the great majority of animals the muscles which they supply run transversely across the eyes and are opposed by muscles running in the same direction supplied by the third pair of nerves. Animals which have their eyes placed forward in the head offer an apparent exception to the general rule, and in these the muscles mentioned pass backward and outward, and have therefore been called "oblique." As the fourth pair of nerves supply only the superior oblique muscles, the function of the nerves and the muscles which they supply must be the same. When the superior oblique acts in conjunction with the inferior oblique of the opposite side, the two eyes move in concert and the eyes are rolled upon their axes. If the two oblique muscles act together with some corresponding action of the inferior obliques, their function is to compress the eyes laterally. In man, if one superior oblique only acted, the eye would be turned downward and outward. If both acted unopposed, both eyes would be turned downward and outward. This would give a very ungainly expression, and could be of no possible use. The real office of the superior oblique muscle is illustrated in its disposition in the eyes of the vast majority of the lower animals. In them the two transverse muscles embrace the eye, and the only action that they can have in all animals, when acting with equal force, is to compress the eyeball. For, although in some animals, from their oblique direction they might be supposed to influence the directions of the eye, this could not be the case in others. In the swan, for instance, the so-called superior oblique muscle runs directly across the eye in its transverse diameter. From the observation of the action of this muscle in man, its use has been assigned by no ordinary authority to be that of "raising and dragging the eye in conjunction with the changes to which the other features are subjected in bodily pain, in agony of mind, and in all this class of passion."[2] But not to mention that there are whole classes of animals in whose features no such expressions are ever recognised, the disposition of this muscle in fish and birds entirely forbids the idea of any such office being assigned to it. It may therefore be concluded that the oblique muscles, taken together, have a twofold action: first, that of rolling the eye; and, secondly, that of compressing it so as to alter its focal length. This affords a means of adjusting the eye to the vision of near objects, and may be regarded as the most powerful mode of adjusting the visual axis of the eye, while the mechanism for the finer adjustment is within the eye itself. The two oblique muscles taken together, then, have a double function, and a double and separate supply of nervous power.

Dr. Hosack, in a paper published in the Philosophical Transactions in 1794 (part 11, p. 222), observed that external pressure was capable of altering the focal length of the eye, so as to adapt it to vision at different distances. "With a speculum," he says, "I made pressure upon my eye while directing attention to an object twenty yards distant, and saw it distinctly; but, endeavouring to look beyond it, everything appeared confused. I then increased the pressure considerably, in consequence of which I was unable to see objects distinctly at a much nearer than the natural focal distance. For example, I held a book before my eye at the distance of two inches. In the natural state of the eye I could neither distinguish lines nor letters, but on making pressure with the speculum I was enabled to distinguish both with ease." Dr. Porterfield[3] objects to this explanation—that in the jack the oblique muscles "are both situated on the under side of the eye, where they decussate each other in the form of a cross"; and he there-

[3] Porterfield on the Eye, vol. i., p. 421, *et seq.*

Digitized by Google

fore argues that the disposition of these muscles is not such as to allow them to compress the globe of the eye: "Had they been so disposed as to embrace the globe in the form of a ring, their contraction might then have squeezed the eye into an oblong form." Having repeatedly dissected the eye of the jack, the author is enabled to assert positively that the oblique muscles have the very disposition which Dr. Porterfield is here contemplating. His assertion respecting their decussation below the eye has evidently arisen from his mistaking the inferior rectus for one of the oblique muscles.

A case, indeed, has been quoted in text-books in which all the muscles supplied by the third pair of nerves were paralysed, and a good accommodation remained.[4] An inference is drawn from this case that the recti and obliqui muscles have really very little power in producing this accommodation. But in this case the fourth nerve was not paralysed; and inasmuch as the peculiar function of the fourth nerve is to regulate the degree of compression exercised on the eyeball by the superior oblique muscle, the case affords additional evidence of the real function of this nerve. In seals the fourth pair of nerves is well developed. The visual focal length would be different in them in the air and in the water for correct vision, and yet a seal can catch a fish as accurately out of the water as in it. The development of the fourth pair of nerves here corresponds with its power of adaptation of the eye to accurate vision under different circumstances. In the monkey, again, where accuracy of vision, in jumping from branch to branch, is so necessary, the fourth pair of nerves is well developed. In the cat, which measures its distance accurately before making its spring, the fourth pair of nerves is also well developed. But here, as in other animals which have a *tapetum lucidum*, the nerves and the muscles which they supply have another function. They not only regulate the antero-posterior diameter of the eye for the reception of light entering the eye, but also focus the light reflected from the *tapetum lucidum*.[5] The power of concentrating reflected light accurately upon an object must give the animal the same knowledge of distance as the focus obtained in ordinary vision. In the flaccid eye of a dead cat the rays of light reflected from the tapetum are nearly parallel. If the antero-posterior diameter of the eye were altered in a living cat, as by the action of the oblique muscle, the rays of reflected light after they had left the eye would converge as they do in the larger eyes of the sheep and the ox; the degree of the action of the oblique muscles in bringing the reflected rays to a focus would then afford an indication of the distance of the object looked at. The amount of convergence of the two optic axes in binocular vision plays, no doubt, a much more important part in the measurement of distance. But by far the larger majority of animals which have a tapetum use one eye only at a time. Where the two eyes are used together the degree of convergence is under the control of the external rectus, which, like the superior oblique, is supplied by a separate nerve.[6]

Those who have called a policeman's lantern a "bull's-eye" have never realised the analogy that exists between the lantern and the real eye. The glare from the anterior surface of the cornea may have originated the name. In the living eye the rays of light reflected from the tapetum may, within certain limits, be concentrated upon any given spot, and the light thus concentrated, as may be illustrated by a slightly concave mirror, is very much more intense than that produced by ordinary scattered rays. If a policeman's lantern were constructed with a slide so that the distance between the light and the reflector could be regulated, the analogy would be more perfect. The rays of light might then be brought to a focus instead of always being directed in paralleled lines.

In ordinary carriage lamps the light is thrown straight forward, which, no doubt, is an advantage to the driver; but for the horse itself the light is required where their natural reflectors throw it—namely, in front of their feet. In the transmission and reflection of light through the transparent parts of the eye some light is necessarily lost. If the whole of the light were reflected from a concave mirror three inches square, and concentrated in a focus of one inch, that inch would receive its natural proportion of ordinary light and nine times the amount of light falling upon each square inch of the mirror.

Savile-row.

[4] Power on the Eye, p. 592. [5] Med.-Chir. Transactions, vol. lxix.

[6] The advantage of judging of distances in binocular vision has probably some compensation in animals, which use only one eye at a time. The more perfect grasp of the eye by the transverse muscles must enable them to focus the rays of light more perfectly than in animals in which the muscles are oblique. The owl, unlike other birds, has its eyes placed forward. This disposition enables it to direct both eyes to the same object at the same time. It has therefore the advantage of binocular vision. In common with other animals which seek their prey at night, it has within a limited distance the power of judging of the position of objects by the angle at which the visual axes meet.

ON DR. BERGEON'S NEW METHOD OF TREATING CONSUMPTION.

BY ARTHUR HILL HASSALL, M.D. LOND.,
FOUNDER OF, AND CONSULTING PHYSICIAN TO, THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

WITH a view to greater precision and uniformity in carrying out the treatment of consumption by Bergeon's method, I have had some analyses made, the results of which I will now detail. The analyses were undertaken at my request by Mr. Edwy G. Clayton, F.I.C., F.C.S., assisted by Mr. F. T. Knott, and they had for their object the determination of the quantity of sulphuretted hydrogen contained in the mineral water or other sulphurous compounds used in the process, both before and after injection.

The analyses of the Eaux Bonnes water used by Dr. Bergeon furnished the following results:—

1. *On the gallon.*

a. One gallon of the water contained
0·60816 grain of H_2S
= 25·94 cubic centimetres
= 1·58 cubic inch.

b. After passing carbonic acid gas, one gallon contained
0·095 grain of H_2S
= 4·04327 cubic centimetres
= 0·25 cubic inch.

2. *On the bottle.*

a. One bottle (700 cubic centimetres) contained
0·00608 gramme of H_2S
= 0·093814 grain of H_2S
= 3·997 cubic centimetres
= 0·2436 cubic inch.

b. After passing carbonic acid gas, one bottle contained
0·000952 gramme of H_2S
= 0·014689 grain of H_2S
= 0·623 cubic centimetre
= 0·003836 cubic inch.

3. *On the half-bottle.*

a. Half a bottle contained
0·00304 gramme of H_2S
= 0·046907 grain of H_2S
= 1·9985 cubic centimetre
= 0·1218 cubic inch.

b. After passing carbonic acid gas, half a bottle contained
0·000476 gramme of H_2S
= 0·0073445 grain of H_2S
= 0·3115 cubic centimetre
= 0·001918 cubic inch.

These results show that the amount of sulphuretted hydrogen contained in the bottled water corresponded closely with that present in the water taken at the source, according to the best analyses. This amount is, however, extremely small, it being only 0·1218 of a cubic inch in the half-bottle of the water, the quantity usually employed by Dr. Bergeon for a single injection.

After 3 litres of carbonic acid gas had been slowly passed through it, the time occupied being twenty-three minutes, the amount of sulphuretted hydrogen in the half bottle was found to have been reduced to 0·001918 of a cubic inch. This result is so far satisfactory, since it shows that the greater part of the sulphuretted hydrogen was carried over by the carbonic acid. No combined sulphuretted hydrogen is contained in the Eaux Bonnes water, and this being so there is no necessity for the employment of an acid, mineral or organic, for the liberation of the gas.

The first published results of Bergeon's method of treatment were all founded upon the employment of the Eaux

Digitized by Google

Bonnes water. More recently, however, recourse has been had to other sources of the sulphuretted hydrogen. Thus, as we learn from Dr. Burney Yeo's recent lecture, Dr. Bardet has employed a definite solution of sulphide of sodium. This is made by dissolving 10 grammes of the salt in 100 cubic centimetres of distilled water. One cubic centimetre of this solution contains 10 cubic centimetres of sulphuretted hydrogen, which is set free by the action of tartaric acid. Of this solution 10 cubic centimetres in 200 grammes of water, = 3086 grains, are employed for each injection, so that if the whole of the gas were liberated, the quantity injected would amount to 100 cubic centimetres, equal to no less than 6·10 cubic inches. Here is an enormous difference in the amount of sulphuretted hydrogen introduced into the system: in one case less than a quarter of an inch, and in the other over 6 cubic inches.

Dr. Coghill has lately employed a saturated aqueous solution of sulphuretted hydrogen, using 1½ oz. to 2 oz. of this in 12 oz. of water; and this quantity, he states, has been well borne by every patient on whom it has been tried. Now 1½ oz. of such a solution should contain—if the water were really saturated at 15° Centigrade and 760 millimetres barometric pressure (these happening to be the temperature and pressure at the time the analyses were made)—3·117 cubic inches of the gas, and 2 oz. 4·156 inches.

Another substance which has been employed is bisulphide of carbon, but I have not seen any statement as to the quantity of this reagent that has been used. Its volatility, however, even at ordinary temperatures, is such that a comparatively small quantity of the liquid reagent (which boils at 46·6° Centigrade) yields with facility a large volume of carbon bisulphide vapour.

It is thus seen that there is a great difference in the amount of sulphuretted hydrogen injected, and yet the results of the treatment have been reported as equally favourable in all cases; the varying amount of the gas used not appearing to make any difference. According to the reports, the frequency of the pulse has been reduced, the temperature lowered, the night sweats relieved, the expectoration diminished, the nutrition greatly improved, the weight rapidly increased, and a great and surprising amelioration in every respect has ensued.

Lucerne.

A CASE OF
PERFORATING ULCERS OF BOTH FEET ASSOCIATED WITH DIABETES AND ATAXIC SYMPTOMS.

By T. DAVIES PRYCE, M.R.C.S.,
SENIOR RESIDENT SURGEON, NOTTINGHAM DISPENSARY.

A. D——, aged fifty-six, framework knitter and hawker, was admitted as a home patient on May 27th, 1886. He had enjoyed fair health up to eighteen months previous to his being treated at the dispensary, with the exception of an occasional winter cough. For eighteen months past he had passed large quantities of urine, and had suffered from great thirst. He was never of temperate habits, and was addicted to "drinking bouts." He was stated to have led a wild life. No history of gonorrhœa or syphilis could be elicited, but strong presumptive evidence of venereal taint was present in the form of two scars, one in each groin, and various syphilis-looking marks on both legs. Eight months previous to admission he complained of pain in his legs, and found that his feet felt dead. At Christmas, 1885, he caught cold, and suffered from an aggravation of the foot symptoms, together with abdominal pain and vomiting. He described at this time as walking on his heels. February, 1886—i.e., three months and a half before admission—the ulcers of the feet first appeared. When seen by me the patient was suffering from [illegible] symptoms of commencing diabetic coma. [illegible] feeble and occasionally intermittent. [illegible] upper limbs were evidently diseased. [illegible] to light. There was diminished [illegible] both feet and also of the lower [illegible] knee-jerk was totally abolished. [illegible] feet were of a livid hue, and [illegible] a fetid odour emanated from both feet. The ulcers commenced as corns. One ulcer of the size of a two-shilling piece was situated over the plantar aspect of the metatarso-phalangeal joint of the right great toe. Its outline was sinuous and ragged. The bones entering into the formation of the joint could be felt at the bottom of the sinus, the metatarsal bone being eroded. A sinus of the same character but of smaller size was situated over the plantar aspect of the head of the fifth metatarsal bone of the opposite foot. Carious bone could be detected. There was also the remains of a partially healed ulcer on the inner aspect of the left great toe. The patient's urine was acid, sp. gr. 1030, contained sugar and a trace of albumen, but no peptone. He died on June 1st (fourth day of treatment) of diabetic coma.

There was no history of gout, rheumatism, or injury in this case. The patient had, however, been exposed to all weathers, and in following his occupation of hawker had walked a great deal. The spinal cord and the nerves of the right lower limb were examined. The only naked-eye changes which could be detected were: (1) the posterior tibial nerve presented considerable enlargement in the lower third of the leg, and was here partially surrounded by inflammatory material, in which was also embedded the atheromatous posterior tibial artery; and (2) the plantar termination of the nerves were discoloured, and diminished in size.

The cord and peripheral nerves have been examined by Mr. Bowlby, of St. Bartholomew's Hospital, who has demonstrated the following changes. In the lumbar region of the cord there is marked atrophy of the cells of the grey matter, which are granular and have lost their processes. In the dorsal region the change is more advanced, most of the cells having completely disappeared. There was no cell exudation in either the white or the grey matter. In the peripheral nerves the changes are most marked in the posterior tibial trunk, where the white substance of Schwann is replaced by granular material which does not stain black with osmic acid. Some of the axis cylinders are normal, but many have atrophied and undergone a fatty change. The anterior tibial nerve shows a similar degeneration, but in a lesser degree, and in the sciatic the bulk of the fibres are normal. There appears to be a slight increase of the connective-tissue basis.

I wish also to mention that Dr. Byrom Bramwell, of Edinburgh, also describes similar changes in the peripheral nerves in this case, with the addition of well-marked vascular disease. He also found vascular changes in the spinal cord, but no ataxic lesion. It will be seen that the changes in the peripheral nerves differ from those recorded by Messrs. Savory and Butlin[1] in the greater amount of true nerve degeneration, and in the much smaller increase of the connective-tissue basis.

The comparatively frequent occurrence of perforating ulcer in locomotor ataxy[2] is well known, but it remains to be shown whether the ataxia in all these cases is due to a typical tabetic lesion of the cord, or, as is probable in the above case, to a peripheral neuritis or nerve degeneration. It is abundantly evident that in the case just recorded the actual cause of the perforating ulcers was a *peripheral nerve degeneration*. It will be seen that a good many of the causes which have been believed to produce perforating ulcer and peripheral neuritis were also present—i.e., cold, alcohol, diabetes, vascular disease, and continued pressure. It is probable that all these played a part in the causation of the disease, but I would venture to assign a considerable share to diabetes and vascular disease. Vascular changes have been found in a number of cases of perforating ulcer, and have been especially insisted upon by M. Pean and other observers. It also appears to me that diabetes may of itself be a cause of perforating ulcer, and this belief is induced by the following considerations: 1. That it is not uncommonly associated with locomotor ataxy, in connexion with which disease perforating ulcer occurs comparatively frequently. 2. That there exists a marked similarity between perforating ulcer on the one hand, and the destructive process of gangrene on the other, which latter is peculiarly liable to occur in diabetes. 3. It has been shown that diabetes does occasionally produce peripheral neuritis. 4. That another case of perforating ulcer has been recorded as occurring with

[1] Transactions of the Royal Medical and Chirurgical Society of London, vol. lxii., p. 373, 1879.

Digitized by Google

diabetes.[3] 5. That the glossy skin of Sir James Paget, which has been shown to depend on injury or disease of the pheripheral nerves, is sometimes seen in diabetes, and that there can be no doubt that this condition is of a somewhat similar pathological character to perforating ulcer. These considerations seem to show that it is possible—nay, more, even probable—that diabetes may sometimes play an active part in the causation of perforating ulcer.

Lastly, with regard to the operative treatment of this affection. It appears to me that the case which I have just related strongly supports Messrs. Savory and Butlin's opinion that the extreme measure (i.e., amputation of a portion or of the whole of the foot) is at best but a doubtful one; for it is evident from the diseased condition of the posterior and anterior tibial nerves that such a procedure would have led to no permanently good result in this case. If, however, amputation is decided upon, I believe it would be advisable not to adhere to hard-and-fast rules with regard to the site of the operation as laid down by various surgeons,[4] but rather to amputate through perfectly healthy tissues—namely, tissues external to or beyond the zone of anæsthesia so commonly present in perforating ulcer of the foot.

Nottingham.

A NOTE ON THE

TREATMENT OF PURULENT OPHTHALMIA.

By CHARLES HIGGENS, F.R.C.S.E.

SEVERE purulent ophthalmia is perhaps the most rapidly destructive disease to which the eye is subject; consequently its treatment has received a large amount of attention. It has always appeared to me that the disease could be rapidly cured if the discharge could be got rid of, or its character altered; it always seemed that it was the discharge which kept the disease going. Constantly washing away the discharge with some astringent and antiseptic lotion gave fairly good results; but the treatment was troublesome, and unless one saw to it oneself was rarely properly carried out. Some years ago Mr. Bader first suggested that persalts of mercury killed or destroyed the pus secreted by a mucous surface; he used to employ an ointment of red oxide of mercury, atropine, and vaseline applied to the conjunctiva, and with good results. The one objection to this treatment was the severe pain it caused, which seemed to me to quite counterbalance any advantage it might have over the washing away treatment. Since cocaine has been introduced, application can be made to the eye of substances which before its introduction caused so much pain that few patients could be found who would continue to use them. I have now treated some ten or twelve cases of severe purulent ophthalmia—some of distinctly gonorrhœal origin—by the following method, and the case reported from notes by my dresser (Mr. Andrews) is a fair specimen. 1. Wash away all discharge, and thoroughly cleanse the eyes with a 5 per cent. solution of boracic acid. 2. Apply thoroughly to the whole conjunctival surface, and fill the conjunctival sac with, an ointment composed of yellow oxide of mercury (16 gr.), boracic acid (20 gr.), hydrochlorate of cocaine (from 5 gr. to 10 gr.), and vaseline (1 oz.); and in some cases I also add 2 gr. of sulphate of atropine. The ointment may be applied with a camel-hair brush, a quill, a syringe with a good wide canal, or in any way that seems most suitable, so long as care is taken that no part of the conjunctival surface escapes it. 3. Cover the eyes with lint plentifully smeared with the ointment, and bandage them. Some pain is caused by the first application, which can be prevented by using a 2 per cent. solution of cocaine before making it; after the first application the effect of the cocaine in the ointment keeps the eye numb from one application to the next, unless the applications are made at very long intervals. The eyes should be examined in about two hours. If there is any discharge the whole process must be repeated; if there is none, the bandage may be reapplied and left for another two hours. As a rule, the ointment requires to be applied every four hours for the first two days, less frequently afterwards; *but the discharge must never be allowed to collect.*

Harry W——, aged eighteen, was admitted into the hospital on March 22nd, 1887. His history was that seven days before, March 15th, the left eye suddenly began to itch, and in the course of two days the eyelids became swollen and discharge commenced. Four days later the right eye became similarly affected; the discharge from both was very free. On admission pus was flowing freely from both eyes, there was much swelling of the eyelids, and intense congestion and swelling of the conjunctiva. There was some difficulty in examining the cornea; but the left was found to be perforated, and there was an ulcer on the right. The eyes were thoroughly cleansed, and the ointment, the prescription for which is given above, was applied (the application to be repeated every four hours), and the eyes were bandaged; quinine was ordered internally and the patient put to bed. The discharge was much diminished after the first application of the ointment. On March 27th, five days after commencing the treatment, there was very great improvement; the swelling of the eyelids had greatly subsided, the conjunctiva had flattened down and was much less congested, and the discharge, which had become less and less, had almost ceased. On April 1st there had been no discharge from the right eye, and very little from the left. The bandage was removed from the right eye. On April 9th, all swelling and discharge had entirely gone. There was slight corneal opacity below the pupil of the right eye. In the left eye there was an opaque flattened cicatrix—to which the iris was adherent—occupying the centre of the cornea; the eye had good perception of light.

Remarks.—The result of treatment in this case was most marked, the only cause for regret is that the patient did not apply sooner; had he done so, in all probability the damage to the left eye would have been prevented. He was not suffering from gonorrhœa, but the case looked like one of gonorrhœal infection.

Brook-street, W.

ON A CASE OF SUNSTROKE.

By A. CHEVALLIER PRESTON, M.R.C.S.

JOHN V——aged fifteen years, was brought to my house on Jan. 7th, 1887, by his mother. He had been cutting grass with a horse reaper, sitting on the machine driving, for the past two days, with no head shade but a cap, in the burning sun. He was gradually seized with pain in the chest and back, accompanied by convulsive movements of the arms and legs and contortions of the face. Has had no previous illness.

On examining him, I found him intelligent and able to tell me what I wanted to know, but his speech was muffled. His face was congested, and there was general redness of the skin of the whole body, with beads of perspiration on the forehead. His arms and legs were in a constant state of rhythmical convulsions. He could not protrude his tongue when asked to do so. Asked for drink. Pupils equal and slightly dilated. No unconsciousness. Pulse 100; temperature in axilla 99·4°; bowels constipated; passed urine freely. Unable to walk without assistance. Thinking the above symptoms were owing to the exposure to the sun in the intensely hot weather then prevalent, I ordered him to be kept in a darkened room, his head to be shaved, and an ice-bag applied to the head and back of neck, with a diet of milk and slops. I also prescribed a mixture containing ten grains of bromide of potassium and five grains of hydrate of chloral, to be taken every three hours, with five grains of calomel at bedtime.

Jan. 8th.—11 A.M.: On visiting him I found him still convulsed, with slight intermissions. No sleep had been obtained. The bowels had not acted. Unable to open jaw. No pain, but feels ill. Pulse 120, hard. Temperature in axilla 101°. Taking nourishment. Ordered ice-bag to be continued to the head, milk and ice by the mouth, and gave five grains of calomel again in powder; injected five grains of quinine hypodermically; the bromide and chloral to be continued.

9th.—3 P.M.: Has had half an hour's sleep, and says he is in no pain. Has taken two pints of iced milk in the twenty-four hours. Had a loose motion last evening, and passed abundance of high-coloured urine. Pulse 110, still hard;

temperature 100°; respiration 26, shallow. When asked to protrude his tongue, he did so, but it got fixed between the teeth, which were gradually closing upon it involuntarily, and I had difficulty in getting it back, as he bit it severely, causing it to bleed much. No power over jaws, but can move his tongue and swallow fluids with difficulty. No paralysis of sphincters or of general muscular system, but it seems to be confined to the head and face. Spasms tetanic. As he had had no sleep, I gave one-third of a grain of morphia hypodermically. To continue medicine.

10th.—11 A.M.: Slept two hours yesterday after morphia. Bowels not open. Pulse 104°; temperature 100; respiration 26, shallow. Conjunctivæ much injected; pupils normal. Fluids return through the nose when drinking. Quite sensible. Can open the jaws a little. Marked opisthotonos and strong convulsions of whole body every few minutes. Ordered chicken jelly to be added to his diet, and increased the dose of chloral to ten minims and gave it less frequently—every four hours.—8 P.M.: Slept at intervals through the day; drowsy. Taking food well. Paroxysms not so frequent, but quite as severe. Pulse increasing in rapidity, 142; respiration 30; temperature 101·1°. Micturates freely. Skin dry. Breathing quick, but free from crepitations or rhonchus. Can open his teeth to the extent of one inch. Quite conscious; says he is in no pain.

11th.—11 A.M.: Has passed a quieter night, but restless since daylight. No opisthotonos during my visit, but persistent trismus. Bowels not open. Pulse 120; temperature 101°; respiration 30. Taking nourishment through a tube. Complained of great pain over cervical vertebræ.—8 P.M.: Has slept at intervals during the day. No twitching during sleep. Taking food fairly well. Skin hot, congested, and dry. Pulse 132; respiration 30. Abdominal diaphragm and intercostals not working in rhythm. Bowels slightly moved. Says he feels better. A severe attack of opisthotonos occurred during my visit, otherwise the paroxysms have been less frequent, though three occurred to-day. Can open the jaws decidedly better, but cannot protrude the tongue. Cannot move his legs, but there is no loss of sensation.

12th.—11 A.M.: Has passed a restless night owing to thirst and the extreme heat of the weather. Fits less strong. Takes nourishment well through tube. Temperature 100·1°; pulse 110°; respiration 25. In no pain to-day. Can put out his tongue better, and can open the jaws wider. Tongue clean. No opisthotonos. Gave a soap enema, which brought away a normal motion.—8 P.M.: Has been restless through the very hot day (100° in shade), but slept an hour in the afternoon. Convulsions much quieter. No opisthotonos. Can open the jaw and protrude the tongue much better. Pulse 108; temperature 100·1°; respiration very jerky and irregular, 26. Asleep when I left. To continue the chloral and bromide every four hours; ordered the yelks of two eggs to be given in milk, and plenty of chicken jelly through the night.

13th.—Noon: Has had a better night and taken all the nourishment ordered. Slept four hours. Still complains of pain in his neck and back. Is having slight convulsive spasms of the whole body every few minutes, but is quite conscious during them. Pulse 110; temperature 101°; respiration 38.—9 P.M.: Very restless during the heavy thunderstorm which occurred this afternoon, and was with great difficulty kept in bed. Convulsions have now returned stronger than ever. Respiration 30 ("Cheyne-Stokes"); pulse 132; temperature 101·2°. Gave four minims of ergotine hypodermically, and added ten minims of the liquid extract of ergot and the chloral mixture every four hours.

14th.—Noon: Slept one hour and a half during the night, and took a fair quantity of milk and broth. Convulsions less severe, but more frequent. Temperature 103°; pulse 160; respiration "Cheyne-Stokes" in character. Mucous râles all over chest. No loss of consciousness, but evidently sinking. Ordered one drachm of rum in milk every two hours.—6 P.M.: Has been gradually getting weaker, but no loss of consciousness. Pulse increasing in rapidity, almost immeasurable. Says he is in no pain. Convulsive twitches all over the body incessantly. Jaw relaxing. Died, quite conscious to the last, at 10 P.M. No necropsy would be permitted.

Remarks.—I much regret that I could not obtain permission for a post-mortem examination. This case appeared to me to be primarily one of spinal meningitis following prolonged exposure to the sun, the lesion being situated in the upper part of the cervical portion of the spinal membranes. There was probably a secondary affection of the cord itself, profoundly involving the motor nuclei, and later on the medullary portion, exciting them to the state of irritability manifested during the progress of the case. The vagus remained unaffected so far as its cardiac fibres were concerned, I think, as evidenced by the little disturbance of the heart's action; but there was, I consider, an involvement of the respiratory centre accounting for the want of coördination of the intercostal muscles with the diaphragm. The persistence of the intellectual faculties and the absence of pain, during the greater part of the disease, points to the non-tendency I have observed in similar cases to the upward spread of the lesion, to the brain itself, as one would expect. The body temperature did not attain the height of many recorded cases of less severity, and the non-loss of control over the sphincters, is, I think, an unusual feature in so serious a lesion.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A SIMPLE METHOD OF PROCURING DEGLUTITION WHERE SUCH IS IMPEDED BY REASON OF EXTENSIVE ULCERATION OF THE EPIGLOTTIS.

By R. NORRIS WOLFENDEN, M.D. CANTAB.,
SENIOR PHYSICIAN TO THE THROAT HOSPITAL, GOLDEN SQUARE.

ONE of the most distressing symptoms accompanying laryngeal phthisis with ulceration of the epiglottis is the difficulty patients experience in swallowing. Especially is this the case in advanced conditions where the epiglottis is more or less completely destroyed. In such circumstances the swallowing of even a teaspoonful of water, or liquid of any kind, is all but impossible, from the violent cough that is excited in consequence of the passage of some of the fluid into the larynx and trachea. Such patients are generally tormented with a thirst which they cannot satisfy, and the painful efforts they make to get down a few drops of liquid, and the terrible spasms of coughing and pain thereby produced, are truly pitiable to observe. One of my patients in the last stage of laryngeal phthisis, and in whom the epiglottis had more than half disappeared from ulceration, lately taught me a "wrinkle" which others may find of service. He informed me that he had discovered a method of drinking even large quantities of fluid with ease, and (in as nearly as possible his own words) said, "I thought of how we used to drink when we were boys, out of a running brook, by lying down upon the bank and putting our mouths to the water, and I resolved to try the plan. I sent for a piece of indiarubber tubing, and found that by adopting the same position I could drink off the whole of a tumblerful of water with ease and comfort." I asked him to give me a demonstration of the feat, and lying stomach downwards upon the couch in my consulting-room, with the head and arms hanging free over the end, and with the feet higher than the rest of the body, he took a large tumblerful of water in both hands, and placing the open end of a piece of indiarubber tubing (about six inches in length and with a vulcanite mouthpiece) in the fluid, and the mouthpiece between the lips, drained off the contents without stopping, and with the greatest ease and comfort. Not the slightest pain or cough accompanied the act, showing that none of the fluid entered the larynx. The feat was the more remarkable to me, who had often seen him making great efforts to swallow fluids, but unsuccessfully, in the sitting position. In the ordinary position a teaspoonful of fluid was as much as he could manage to get down, and this was accomplished only at the cost of much pain and terrible paroxysms of coughing. The plan is simple enough, and is one which will procure relief for other patients afflicted with the same terrible laryngeal conditions; as I have never seen it applied before, I venture to mention it to those who have to treat similar conditions, and I am sure they will find it an excellent method of alleviating one of the most distressing sufferings of patients of this class.

PUNCTURED WOUND ENTERING THE SPINAL CANAL.

BY ROBERT W. WALSH, M.R.C.S., L.S.A.,
RESIDENT ASSISTANT, EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL, E.

THE following case, which lately came under my notice, may possibly be of interest.

H. B——, a boy aged twelve, was brought to the Children's Hospital, Shadwell, one evening, with the following history. Some hours before I saw him he had been playing with his sister, and the latter had accidentally wounded him in the back with a pair of scissors. The wound appeared so trifling that the patient was not brought immediately to the hospital, but continued to play about, and then had his tea as usual. Shortly after this meal he was seized with sickness, and vomited once or twice. His back was looked at by his father, and his shirt was found quite wet. He was then brought to the hospital, where I saw him. Before I could look at the wound the boy was seized with violent retching, and brought up some watery fluid. I had the boy undressed, and found his shirt and under-vest saturated with fluid of some sort. On examining the back, I saw a small punctured wound about a quarter of an inch long, and of such a character as would be expected from the nature of the instrument with which it was inflicted. Its situation was a little to the left of the spinal column, almost exactly in the mid-dorsal region. A probe introduced passed in the direction of the spinal canal, but was arrested by bony substance, which was apparently not bare; the instrument did not appear to enter the canal. The depth of the wound was just an inch. The boy's father would not leave him in the hospital, so I closed the wound with a small pledget of lint dipped in collodion, and sent the boy off, with instructions to come again if any bad symptoms appeared. He came next day, having been again sick and the wound having reopened. As admission was still refused by the father, I again examined the boy, and found matters almost exactly as before—the shirt and vest wet through, and the boy retching violently while in the room. In watching the wound, a small drop of clear watery fluid could be seen to collect at the lower angle of the puncture, and then roll slowly down the back. I united the edges of the wound with a fine silk suture, and sent the patient home as before. I saw him again in a week, when the wound was healed, and there had been no more sickness or other bad symptom. I have seen him once or twice since, and he remains perfectly well. It seems somewhat remarkable that in what was evidently a punctured wound entering the spinal canal, and remaining unclosed for over eighteen hours, there were no symptoms indicative of either spinal meningitis or irritation beyond the violent sickness; and it is also significant that this sickness continued as long as the wound remained unclosed, and ceased immediately closure was effected.

Shadwell.

CASE OF SUPPURATIVE HEPATITIS OCCURRING IN GENERAL PRACTICE.

BY CHAS. E. MONRO, L.R.C.P.ED., M.R.C.S.

C. C. S——, aged thirty-four years, formerly a sergeant in the Royal Artillery, went to India about the beginning of the year 1877, and was stationed at Ferozepore. Whilst there he contracted several attacks of malarial fever, and one of acute dysentery, lasting a fortnight; this was followed by chronic hepatitis, and an abscess was suspected. He was then a teetotaler, and had never suffered from any previous illness or syphilis. He recovered, was invalided home in May, 1880, and purchased his discharge, at the time feeling quite well. He then followed various occupations, but became very intemperate, and had one attack of delirium tremens. About eight months ago he first began to feel ill, with loss of appetite, wasting, progressive debility, and dyspeptic symptoms; he became sallow, and passed acholic stools, and latterly had diarrhœa with much mucus. There was a considerable degree of splenic tenderness, with slight splenic enlargement, also retching and vomiting. A tumour gradually formed in the right hypochondrium, extending to the epigastrium, with great pain. The patient could only lie in a position inclining to the right side, and with his knees drawn up. Rigors set in, and I diagnosed hepatic abscess. The temperature never exceeded at the time of my visit 101·5° F. At length the tumour obviously fluctuated.

On March 17th last, in consultation with Dr. Seymour Taylor, the abscess was aspirated, and fifty-one fluid ounces of pus removed. The patient rapidly recovered, and, from an almost moribund state, is now well and hearty, has gained much in weight, and has gone into the country for change of air; he is also able to walk four or five miles without feeling fatigued. The appearance of the abdomen is natural, the area of hepatic dulness a little extended. Urine: sp. gr. 1021; no albumen or casts; deposit of lithates. Thinking that it might possibly be a suppurating hydatid cyst, Dr. Seymour Taylor and I carefully examined the pus microscopically. There were no hooklets, but pus cells, broken-down hepatic tissue, crystals of cholesterine, and columnar epithelium. I saw the patient on June 23rd; he was then in good health.

Penge.

COMPLETE RETROVERSION OF THE UTERUS IN A VIRGIN.

BY WM. J. FRASER, B.A., M.B. DUB., &c.

THE following note may be worthy of record, and first I will give the girl's story or history, and then what I found on seeing her.

Mary Jane W——, aged twenty-three, of a loose build, was a general servant living at Taunton, and was in her usual good health, when on Thursday night, July 29th last, on going to bed she felt a sudden pain in the genital organs, with a total inability to pass urine. She continued in great pain all night, and vomited some watery stuff. About 5 A.M. her master asked a doctor to see her. She continued about the same, passing no urine, bowels costive, and in pain. On Sunday, Aug. 1st, a catheter was passed but drew off no urine. A swelling was then noticed in the abdomen, which increased, the pain being intense at times. Warm stupes relieved her. She afterwards passed a drop or so of urine, but she says she was "always wet." She was advised to go to the Taunton Infirmary, but her mother preferred bringing her home, which she did on Aug. 5th. When I saw her on her arrival, about 11 P.M., it being late and she exhausted by vomiting and the journey, I gave her a good dose of chloral, promising to see her again in the morning. At my visit on Aug. 6th, on examining the abdomen externally, a tumour was felt similar to about a five months' pregnancy, but more inclined to the right side, where it felt hard, though it was soft and movable on the left side, and if pressed on, she said, in answer to my question, that it made her feel as if she wanted to micturate. Per vaginam the examination revealed a chaotic mass; none of the familiar landmarks were felt. The posterior part was occupied by a round hardish mass tapering towards the pubic arch, under which was felt a round, cord-like substance, and on passing the finger further up an opening like the patulous os was felt. I now saw that I had to deal with a case of complete retroversion, causing retention and distension of the bladder and difficulty of defecation. I at once tried to pass a No. 9 gum-elastic catheter in the usual way, but totally failed; so placing her on her back, and with ocular aid finding the now retracted meatus, I came to the obstruction about an inch and a half above, which by gentle pressure I passed, thus being enabled to get into the bladder and to draw off four pints and a half of urine, the tumour disappearing and giving the patient immediate relief. Now, knowing the cause, I sent for a few pessaries, drawing off the urine twice a day; on August 10th I tried without chloroform to return the uterus, but failed. My senior partner, Dr. Gervis, being away for a few days, I waited till the 14th, when (he giving chloroform), after a good deal of difficulty, I succeeded in getting the now enlarged uterus into place, and kept it there by a Blackbee's pessary. Rest in bed was ordered, and a soothing mixture given. On the 18th the bladder had not regained its tone. The catheter was passed as before. There was no pain now, the bowels were open, and the girl felt better, but weak. In the evening she complained of pain caused by the pessary, which I removed, first passing the catheter. On the 17th, at my morning visit, I was told she had passed a little urine, and the catheter was not used. From this date she improved. She was kept in bed for a

Digitized by Google

for ten days, and the pessary was not again introduced. After this she was up and about, and seemed as though she had never undergone the above three weeks' experience.

"Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morbum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare."—MORGAGNI *De Sed. et Caus. Morb.*, Ep. iv. Proœmium.

LONDON HOSPITAL.

DISEASE OF THE ANKLE-JOINT; EXCISION OF THE ASTRAGALUS.—COMPOUND FRACTURE INTO THE ANKLE JOINT; OPERATION.—DISLOCATION OF THE ASTRAGALUS.

(Under the care of Mr. RIVINGTON.)

THE following cases are illustrative of the surgery of the ankle joint. In two it was necessary to remove the whole of the astragalus, and in another a large portion of that bone was taken away. It will be seen on perusal of the notes that excellent results followed the methods of treatment adopted. In the majority of instances it is possible to reduce the astragalus when displaced forwards by manipulation when the calf muscles are relaxed; failing this, after division of the tendo Achillis. But there are cases, of which Case 3 is an instance, where no amount of skilful manipulation can effect reduction, and it is necessary to excise the bone. It is recommended by some that this removal of the bone be postponed for some time after the receipt of the damage, as the operation is then safer.

CASE 1. *Disease of ankle joint; excision of astragalus; cure.*—Rosetta C——, six years of age, was admitted in March, 1885, with disease of the left ankle joint. The parts were inflamed and swollen; there was free discharge from open sinuses; the probe passed readily into the joint, and bare bone could be felt. The patient had been in hospital at Bristol, where the sinuses had been freely opened. The foot was at first placed on a splint. After some days' rest the patient's ankle was explored, and the disease of bone being apparently limited to the astragalus, that bone was readily removed. When the patient was discharged one or two sinuses remained open. In November, 1886, she came under care again on account of an abscess at the back of the heel. This was opened, and a considerable quantity of pus evacuated. At this time all sinuses had healed, and the abscess wound having closed, the patient was discharged cured on Nov. 26th. She was last seen in April, 1887, when she could run about, and little difference beyond a diminution in the depth of the foot from the malleoli to the edge of the sole could be detected. Flexion and extension could be performed at the ankle joint. This patient was shown to the visitors at the district branch of the Metropolitan Branch of the British Medical Association at the April meeting.

CASE 2. *Compound fracture of left tibia into the ankle joint; fracture of left fibula with dislocation of the foot outwards; fracture of right tibia and fibula; secondary amputation of left ankle joint; cure.*—J. A——, aged fifty, [illegible] was admitted on January 28th, 1882. He had been [illegible] scaffolding a distance of about eighteen feet, and part of the woodwork fell on his legs, producing the injuries above mentioned, for which he was admitted. The [illegible] fibula were fractured at the junction of the [illegible] middle thirds, the tibia being much comminuted, [illegible] smelling. The left internal malleolus was [illegible] transversely, the upper fragment being forced [illegible] by the eversion of the foot. The joint [illegible] malleolus could be plainly seen, a wound [illegible] through which the upper fragment [illegible] projected, communicating freely [illegible] posterior tibial artery was uninjured, [illegible] case soon after admission, and decided [illegible] antiseptically. A carbolic spray played on [illegible] the joint was well syringed out [illegible] water, and the ankle then dressed antiseptically. The limb was kept at rest by means of a back splint and an outside splint with a footpiece. The right tibia and fibula were put up as usual—viz., on a back splint with outside and inside splints. Good position was obtained in both limbs. The patient was then given a hypodermic injection; the right tibia and fibula were swung, whilst the left limb was kept steady by means of sand-bags. A good deal of constitutional disturbance, swelling of the left leg, and suppuration followed, necessitating incisions. On Feb. 10th the limb was very boggy from the ankle to the middle of the thigh. A sinus was found to have opened midway between the ankle and the knee in front. An opening was made above the knee and a quantity of pus was evacuated. On Feb. 13th the whole of the skin in front of the leg was found to be undermined, and there was free suppuration. The incisions had to be enlarged on the 16th, and drainage tubes were inserted. By the 27th the limb was more healthy and the swelling had disappeared. A fragment of bone, comprising the whole of the internal malleolus, was removed. Erysipelas appeared on the nose and face, but there was no rigor, and the temperature was 101° only. On the 28th a free incision had to be made on the outer side of the leg. On March 4th three fragments of necrosed bone were removed from the ankle. By March 16th the wounds at the upper part of the leg were granulating; a collection of pus was opened in front of the ankle. The splints were removed from the right leg; good union had occurred. On April 3rd antiseptics were discontinued, and the wound dressed with oiled lint. On May 2nd there was no union in the fracture of the left tibia. The wound looked healthy, and there was very little discharge. It was very difficult to keep the fracture in position. On the 15th the wound required dressing every other day, and had a most unpleasant odour. The temperature varied from normal to 100°. On June 7th the wound was enlarged, the end of the fibula was removed, the lower end of the tibia chiselled, and a thick section of the astragalus taken away. The bones were very soft. The parts were dressed with oiled lint and cotton-wool, and the limb was kept in splints. The process of healing was slow, and great difficulty was experienced in keeping the foot in position. On July 4th the foot was in better position. Some amount of union had taken place on the 31st; the inner opening was very small, and the outer one closing. The patient's condition had much improved. On August 8th the sinuses had not quite closed, and the leg and foot were œdematous. On Sept. 10th a silicate of potash bandage splint was applied, which on the 18th was slit up in front, eyelet-holes made, and laced. Patient wheeled out into the garden. On Oct. 9th there was fair union, with movable joint. The foot was placed in a M'Intyre splint; subsequently the silicate of potash bandage was employed. The patient did not go out of the hospital until he had been in about twelve months. He was then going about on crutches. He was last seen on April 26th, 1887, when he was shown to the district branch of the British Medical Association. He had had a serviceable foot for a long time, with some movement at the ankle. There was no wound or sinus, and he was able to bear weight and walk on the foot.

CASE 3. *Subastragaloid dislocation of the right foot outwards, with displacement of the astragalus; removal of the astragalus.*—William D——, aged forty, bricklayer, was admitted on October 6th, 1880. He had fallen from a height of about twelve feet on to his feet. On examination it was found that the foot was elongated from the ankle forwards and turned outwards, whilst the astragalus itself was twisted, the head being prominent near the inner malleolus and the body pushed backwards and outwards, so that the posterior edge of the astragalus could be felt behind the tibia. The leg was much bruised. Attempts at reduction, including division of the tendo Achillis, failing, and the patient not consenting to the removal of the astragalus as advised by Mr. Rivington, the foot was left till Oct. 26th, when it had become still further displaced. With the patient's permission the astragalus was then excised under the spray. The foot had previously been dressed antiseptically as a precautionary measure in order to guard against possible sloughing of the soft parts over the bone. The neck of the astragalus was found to be embraced by the tendons of the tibiales muscles, and the tissues over the head of the astragalus were black and sloughing. The tendo Achillis was united by suture on removal of the bone. The wounds were dressed with gauze till Nov. 20th, when antiseptic dressings were left off, the discharge smelling offensively. On the 22nd a sinus at the upper part of the

Digitized by Google

leg was laid freely open, and a large quantity of pus evacuated. On the 28th the leg was œdematous and the foot much swollen. In the wound at the ankle there were numerous sloughs, one being the tendon of the tibialis posticus. A fortnight later an abscess was opened over the outer ankle. In another week the wounds were granulating healthily and rapidly filling in. The temperature had always stood below 100° since the operation. The patient made a good recovery, with a useful foot.

NEWCASTLE-ON-TYNE INFIRMARY.

TWO CASES OF ELEPHANTIASIS OF THE LEG, IN ONE OF WHICH THE FEMORAL ARTERY WAS LIGATURED; REMARKS.

(Under the care of Mr. PAGE.)

FOR the report of the following cases we are indebted to Mr. Maynard, house-surgeon:—

CASE 1.—W. S——, aged twenty-one, single, glassmaker, born in Sunderland and never been out of the place all his life, was admitted on March 24th, 1887. His history contained little of note, except that he was born with the left thigh and leg larger than the right, and that, as he grew older, the calf enlarged more than the thigh. The skin was natural until he was fifteen years old, when it began to get rough and thickened. He has had a few "attacks of inflammation" in the leg—the first nine years ago. While at work he noticed the calf (from knee to foot only) red and inflamed after he had felt ill for about an hour (no vomiting or shivering). He went to bed and stayed there six weeks. The skin was dry during the attack, and never cracked or discharged at all. It was kept dredged with flour. He was delirious, and had attacks of dizziness. All his symptoms were worse at night. After this attack he felt quite well, and the leg diminished somewhat in size. He remained free until three years ago, when he had another "attack." This kept him in bed two months, and in its course three warty excrescences, the size of small walnuts, appeared behind the inner ankle, ran into one another, and spread up nearly to the knee. They cracked and discharged thin, yellowish-white, sticky matter, without itchiness. They ran the same at night as in the day, not more. The discharge has continued until lately, increasing whenever he "caught cold." After this attack the leg remained larger and harder than before, though he went about his work as usual. During the last three years he has had five or six similar attacks (the last three months ago), lasting from one to four weeks each, and leaving the leg larger each time. When a baby he was circumcised, his mother says.

On admission the condition was as follows:—All organs healthy. Penis small and buried in scrotum, which forms the prepuce, as it were, and a tight one too, the glans being completely hidden. Testes normal; pubic hair short and scanty, and does not grow towards umbilicus, as is usual in men. Left leg: The thigh looks like a continuation of the trunk, so large is it; the skin covering it is everywhere normal, without œdema, and there are no enlarged glands to be felt. The femoral artery can be felt deeply situated in Scarpa's triangle, and much larger in calibre than the right. The thigh feels firm and elastic, but not hide-bound, fluctuating laterally but not vertically. When he moves the limb (apparently an easy matter) the different thigh muscles feel very large. The bone cannot be plainly made out. At the knee the landmarks reappear, and can be felt (patella, &c.). Below the knee the leg enlarges greatly, and the skin alters. In the upper third it is like the thigh, but below that it becomes indurated, roughened, and presents numerous slightly-raised, flattened, red nodules—like blind boils—each, he says, he can distinctly trace to a blow. The lower portion of the leg presents a truly remarkable sight. It is immensely large, nodulated and gnarled on the surface like an old oak, the nodules lying close, and being of the size of shillings and half-crowns. The whole feels hard and tense, but indistinctly elastic. The surface of the patches is red, shining, and smooth; not inflamed. The skin between is dry and scaly. The skin over the last three inches of the leg resembles ichthyosis; much fissured, dry, and warty. There is a deep sulcus at the ankle, and then the dorsum of the foot rises up with a swelling similar to that of the leg, except that the skin is smooth everywhere but above the second toe, where there is a small warty excrescence like a small dried sea-anemone. The toes are spread out and flattened. The measurements on admission were as follows:—Right leg: middle of thigh, 19 in.; at patella, 10 in.; middle of calf, 12½ in.; lower, broadest part, 8¾ in. Left leg: middle of thigh, 26½ in.; patella, 24½ in.; middle of calf, 31 in.; lower, at broadest part 32½ in. No filaria were found, and the blood and urine were normal.

The patient was treated in bed with a Martin's bandage, and at the end of two weeks the calf was reduced in circumference by seven inches, the thigh only one inch, and the foot not at all. The tibia and femur were much enlarged, being nearly three times their natural thickness. During the treatment he had two attacks of erythema on the skin over the dorsum of the foot, accompanied by a slight rise of temperature, and the bandage had then to be stopped for a few days. On May 20th he got up, with the bandage on. On May 23rd the leg was much larger, though still soft. On June 1st he went home, and was told to use the bandage. Amputation in the thigh was discussed, but was put aside for the present.

CASE 2.—Lawrence M'C——, aged forty-six, single, seaman, a native of the West Indies (Nevis), where he lived until he was sixteen years old, was admitted on July 20th, 1886; his history was briefly this: General health always good; hard drinker; no syphilis. When sixteen years of age he first noticed swelling about the right ankle, which gradually spread up the leg, increasing slowly in size, but never gave him any inconvenience or pain until seven years ago, when he began to feel it heavy and a dull aching numbness about it, and which compelled him to leave the sea and do light work. Never had any attacks of inflammation in the leg, only a few boils and pimples on it. Until four years ago the skin resembled that of the other leg, but it turned darker in colour, and scabs began to form, discharging blood and matter. This discharge ceased when lying idle, and was worse in winter. His father died of phthisis; his mother and one sister had a kind of elephantiasis, though it was permanent, never varied in size like his, and gave them no pain. He is of African descent.

On admission the thigh was normal. Below the knee the leg was uniformly enlarged and hard; the skin was dark, dry, and scaly. Here and there were small excoriations discharging pus. The ankle was included in the swelling, and there was some swelling of the dorsum, slight in amount. He had a hydrocele of left tunica vaginalis testis, which was tapped twice, and contained ordinary hydrocele fluid. Blood and urine normal.

Rest in bed not producing much change, on October 1st Mr. Page ligatured the femoral artery in Scarpa's triangle. The artery was small in calibre, so much so as to make a double femoral anomaly probable. After the operation the leg gradually decreased in size, but never became as small as the left, nor the skin as supple, though the excoriations healed. The tibia could be felt to be much enlarged—half as thick again as, or more than, the opposite bone. At the end of the month he left with the wound not quite healed.

He was re-admitted on April 20th, 1887, with the leg almost as large as on his first admission and the skin much excoriated. He had been on the tramp, and fared badly. Had bronchitis and was low. With good feeding and rest the leg improved, and then, as the man declined any further operation (amputation through the thigh having been suggested), he went out.

Remarks by Mr. MAYNARD.—These cases induce comment mainly as regards their etiology and treatment. Filaria could have taken no share in producing Case 1, though in Case 2 it would be difficult to prove that their influence had never been at work. Hutchinson's idea—viz., that of constantly recurring cutaneous erysipelas,—attractive as it seems, would hardly explain it in the face of the great enlargement of the bones in both cases, and in Case 2 the absence of any inflammatory history. The general congestion in the limb caused by local inflammation could not be expected to produce such osseous hypertrophy. As regards treatment, rest with elastic pressure produced good results while it was persevered with, but only so long. Ligature of the femoral in Case 2 was certainly temporarily very encouraging, but afterwards disappointing. Indeed, when one remembers the great enlargement of the bones, the conclusion one must come to—at any rate in cases where it is present—is that no amount of rest or elastic pressure can cure, and nothing short of amputation will permanently relieve. In Case 1 this would have been a very formidable business.

EDINBURGH ROYAL INFIRMARY.

SIMPLE FRACTURE OF THE FEMUR WITH RUPTURE OF THE POPLITEAL ARTERY AND VEIN; AMPUTATION THROUGH THE THIGH.

(Under the care of Professor ANNANDALE.)

FOR the notes of the following case we are indebted to Mr. D. G. Marshall, house-surgeon.

J. S. T——, aged fifty, admitted at 5 P.M. on Feb. 18th, 1887, suffering from an injury to the right thigh. A few hours before admission the patient was working in a mine when a mass of coal and stone weighing several tons fell upon him. At the time of the accident he was lying on his left side, and the mass struck him on the outer side of the right thigh and leg. He struggled violently to release his legs for about a quarter of an hour, but was unable to do so. At the end of this time assistance arrived and he was released; temporary splints having been employed by a medical man, he was conveyed to Edinburgh (a distance of fifteen miles) by train.

On admission, the patient was suffering slightly from shock, but was perfectly conscious. On removing the temporary splints, he was found to be suffering from a simple transverse fracture of the femur about two inches above the condyles. There was a little shortening of the limb, with a slight deformity at the knee; this was easily reduced, and seemed to depend on a displacement of the tibia forwards. There was some swelling of the limb, both at the seat of fracture and in the calf; below the knee the limb was cold to touch, and no pulsation could be felt in either of the tibial arteries. No splints were applied, the injured part being simply swathed in cotton-wool and laid on pillows. During the evening the condition of shock wore off, and some degree of warmth returned to the leg as far down as the ankle, the foot still being cold. Temperature in the axilla 99·8°.

Feb. 19th.—Morning: The cold portion is limited to the foot and leg about two inches above the ankle joint. Temperature 99·6°. Evening: The leg is cold over the lower two-thirds. Temperature 99·8°. Patient feels comfortable, excepting that his foot has a "dead" feeling.

20th.—Condition unchanged, excepting that the foot has a slightly mottled appearance.

21st.—Lower two-thirds of the leg and the foot perfectly cold; the mottling of the skin very marked. The patient having been put under chloroform, Mr. Annandale made an incision on the inner side of the limb over the seat of fracture, when some dark-coloured blood escaped. On passing his finger into the wound he found the joint was implicated, and at once proceeded to amputate at the junction of the lower and middle two-thirds of the thigh. On examining the parts removed, the femur was found to be fractured in a transverse direction about two inches above the condyles; there was a large rent in the posterior part of the capsular ligament of the knee joint, and both the crucial ligaments were torn through. The popliteal artery and vein were torn completely across; the separated torn extremities of the artery were of a pointed shape and twisted in appearance. The muscles of the calf were infiltrated with blood.

During the evening after the operation the temperature was 99°; pulse 84. On the 23rd the temperature rose to 102·2°. There was slight tension in the flaps, and some stitches were removed. After this he made good progress. The stump healed rapidly, and he was sent to the convalescent home on the 31st of March.

Remarks by Professor ANNANDALE.—This case seems worthy of record; firstly, on the question of diagnosis and treatment. Rupture of the vessels is in few surgical works referred to as specially likely to accompany this fracture. The sharp edge of the lower fragment drawn backwards and downwards is brought in close proximity to the vessels, and supposing the symptoms of injury to the vessels to be not well marked, the severity of the case might be overlooked. Billroth, in his Clinical Notes, records such a case, treated with plaster-of-Paris bandages, followed by gangrene. His patient died after amputation of the thigh. The second point of the case is the very good example of arrest of hæmorrhage by natural means. The quantity of blood effused into the tissues was very small, and the ends of the arteries looked as though they had been twisted with forceps.

OPHTHALMOLOGICAL SOCIETY.

Anatomy of the Capsule of Tenon.—Discussion on Toxic Amblyopia.

A SPECIAL meeting of this Society was held on the 23rd ult., Mr. H. Power, F.R.C.S., Vice-President, in the chair.

Mr. LOCKWOOD exhibited a series of specimens, brought from the museum of St. Bartholomew's Hospital, bearing on the Anatomy of the Capsule of Tenon. They showed the continuity of the capsule and the sheath of the optic nerve behind, and its relations to the conjunctiva in front. The suspensory ligament of the eye and its attachments to the wall of the orbit were clearly seen from a number of points of view. The intra-capsular ligaments of the various muscles and their relation to the recti were demonstrated, and also the inward bend of the superior rectus. Lastly, attention was drawn to the tunica adventitia oculi and to the cheek ligaments of the recti. He thought the latter might be of considerable importance in relation to squint operations.—Mr. POWER spoke of the importance of an accurate knowledge of the precise attachment of muscles and of the precise effects of division of tendons. Everyone must have experienced unexpected and unexplained instances of failure in the treatment of cases of squint.

Mr. NETTLESHIP opened the discussion on Toxic Amblyopia. In reference to the question of alcohol, he said that he had met with no instance of amblyopia in drinkers who did not smoke, but he thought that in smokers alcohol might contribute in determining the onset and degree of the affection, and he instanced the case of a man who smoked from a quarter of an ounce to half an ounce of mild tobacco a day, and who had lately taken to drinking, whose vision, which had been failing for a month, was—R.E. $\frac{2}{3}$, L.E. $\frac{2}{4}$; and also another case of a man aged forty-nine suffering from alcoholic paralysis who was a large smoker, but had no central defect for colour; his vision improved very materially when he partly left off drinking and smoking. Cases seeming to show that alcohol had no effect were common—that is, where the leaving off tobacco was sufficient to effect cure or improvement, the alcohol being indulged in in undiminished quantity. Considerable pallor of the whole disc was common in severe cases, and might persist, though the vision improved. There were forms of central amblyopia in non-smokers. There was a hereditary form in which families of young adult males got amblyopia rather rapidly, some being smokers and some not. Apart from these, he had only seen two cases of central amblyopia not attributable to tobacco. One was in an old man of seventy-two, who had not used tobacco for twenty years, and whose sight had been failing for eight years; his discs were rather pale and the arteries diminished; he remained *in statu quo*. The other patient was a man of twenty-four, whose sight failed whilst he was extremely ill with syphilitic rupia; there were no ophthalmoscopic changes, but a scotoma exactly as in tobacco cases. He had not used any tobacco for eight months, and his sight had only begun to fail three months after he left it off. He had met with this form of amblyopia in a man who only smoked three-quarters of an ounce of shag a week. As to the length of time a person must have been a smoker, he instanced the case of a man who took to smoking at the age of twenty-nine and a half years, consuming an ounce of shag daily; he was also a heavy drinker. At the end of six months he took the pledge and kept it for six months, and between two and three weeks later his sight began to fail. In another instance a man, aged fifty-two, had characteristic central amblyopia after being a smoker for three years. He (Mr. Nettleship) had met with tobacco amblyopia in father and son once, and once the son of a patient was found to have locomotor ataxy and progressive atrophy of his discs. In two patients (sailors) there was a history of an attack of night-blindness whilst at sea some years previously. He had only met with one instance of a second attack in a patient who had been cured by giving up tobacco, and then took to it again four years later; at the end of another year his vision again failed. In the speaker's experience cases might recover with complete or partial disuse of tobacco. Sometimes cases did not progress beyond a certain point, although smoking was not discontinued.—Mr. MCHARDY referred to a case of a gentleman, aged fifty-

Digitized by Google

two, who had commencing cataracts, which had been supposed to be the cause of his failure of vision. When tobacco was given up he made marked improvement in twelve weeks, and in four months had good colour vision. He believed that some severe nervous or mental shock would always be found in these cases, if persistently inquired into, and instanced several cases supporting this view; he did not believe that the intermission of tobacco in those habituated to it had anything to do with the causation. All tobacco must be stopped, and he was decidedly in favour of giving strychnine; it must be given so as to produce its full effects, and then decided improvement would be noticed in a few days; by the end of ten or twelve weeks all the recovery possible would have taken place, and most cases did recover completely. He had observed that a considerable proportion of the patients had suffered from malaria. He had never seen it under thirty-two years of age; most of the patients were between forty and fifty.—Mr. EDGAR BROWNE spoke of the difficulty they had in Liverpool in tracing their cases, most of the patients being sailors. He had met with one instance of a relapse, and he thought that perhaps their rarity was only apparent, inasmuch as the patient would know what to do if he had a relapse, and so would not come for advice. As a rule the patients did leave off smoking for a time, and if they returned to it, a milder tobacco was used. He had seen no case of amblyopia due to alcohol alone, and he had seen no case in women—a strong point against the alcoholic theory, as women drank just as freely as men, but did not smoke. Of his forty-nine patients, seventeen were heavy drinkers, four teetotalers. Persisting pallor of the disc was the rule, notwithstanding improvement in sight. He had seen one case in which the blindness was permanent, but there was a history of a blow, and he thought there might have been some true atrophy in that case. The affection was common about thirty, but most common between forty and fifty. He believed that some impairment always preceded the onset, and in sailors there was always the great change in habits as a factor. The lowest quantity he had ever known to cause it was a daily allowance of two ounces of twist. He had tried nitrite of amyl, but only once with benefit; in that case, when the face was flushed, there was a temporary improvement of vision.—Dr. HILL GRIFFITHS gave the results of his experience. Of twenty-seven patients who completely recovered, eleven had entirely given up tobacco; the others had reduced the quantity used. Of twenty-four patients in whom partial recovery had taken place, eleven had entirely discontinued the tobacco, and nine had lessened the quantity taken; in one woman a relapse took place during the treatment, because she took to smoking again. Of eleven failures, five patients had entirely given up tobacco, and two had made no reduction. Of the three patients who had got worse, two had smoked as usual all along; the other had given it up. Therefore there was a tendency to recover even without complete disuse of the drug, as one-third of the patients had only reduced the amount taken. He had not met with atrophy of the disc. He had seen five cases independent of tobacco: the first patient was a woman much pulled down by repeated pregnancies, who did not smoke, and whose impairment of vision was exactly like that seen in purely functional cases; the second was also a woman, a heavy drinker, who did not smoke, and who made a rapid recovery; the third was also a drinker, who did not smoke; the fourth had been a smoker, and was a drunkard; he had amblyopia, but no central scotoma; the last patient, like the first, had contracted fields and resembled a functional case. He had seen fourteen instances in women, and had met with two cases in men under twenty-three. From five to six years' smoking was the shortest period in which he had known the disease to be produced. He had seen hæmorrhages in several cases, all in heavy drinkers.—Mr. ADAMS FROST had not met with a case of central amblyopia without tobacco. He had seen one case of non-central amblyopia in a lady who did not use tobacco, but it might have been consecutive to an attack of typhoid fever. Nine of his patients were total abstainers, and some were heavy drinkers. All improved, and recovery usually took place in from six weeks to three months. The youngest patient he had seen was twenty-five. He had no faith in strychnine, but found iodide of potassium very useful.—Mr. LAWFORD, with Mr. EDMUNDS, referred to a fatal case of alcoholic paralysis in a man aged fifty-six. On examination, changes were found in the optic nerves; these were central higher up and lower down; they were sector-like and at the outer side. They did not believe the changes ought to be attributed to the alcohol, but rather to the tobacco. Unfortunately no examination of the patient's sight had been made during his life.—Mr. J. HUTCHINSON, jun., mentioned one case of amblyopia apparently due to alcoholism in a heavy drinker aged forty-two, who made a rapid improvement. He had once seen the affection appear in one eye six months before the second began to fail. The patient smoked half an ounce of shag daily. The eye which had failed first was the first to improve. He also mentioned the case of a man, aged sixty-three, in whom the onset was gradual, and who had a large central scotoma, whose distant vision was bad, whilst his near vision was good. He improved. Strong tobacco was usually the cause, but he had one case where a daily allowance of an ounce of "May Blossom" had caused it, and one where cigars only had been used. He thought it fairly common to find a scotoma in the yellow field, and had once met with a scotoma for all four colours. In two cases there had been a scotoma for white; in one case the scotoma was wholly absent for a time.—Mr. JESSOP had found a history of tobacco-use in all the cases he had seen, and of strong tobacco in all but one. In most of them he thought there had been some sort of trouble. In alcoholic paralysis there was no central scotoma or limitation of the field of vision. He had seen the affection in two women, both smokers.—Mr. MORTON had only seen this amblyopia in tobacco cases. Three teetotalers recovered after giving up tobacco. In one case of persistent pallor of the disc that he had long under observation the vision remained stationary for several years. Once he had seen retinal hæmorrhages. He had not found shock play any part in the causation. Strychnine was useful in his experience. He had seen two cases in men under twenty-three. Shag was the tobacco that most frequently caused it.—Mr. GUNN said that the age was from thirty-five to fifty-five most frequently. The failure of sight was often sudden and rapid, and he thought it occurred more often in those engaged in open-air occupations. He had known half an ounce daily of coarse tobacco cause it. In all cases tobacco had been used, and he believed that both total abstainers and drunkards were more liable to it than moderate drinkers. Only one patient did not recover on leaving off tobacco; considerable improvement followed on lessening the quantity of tobacco used. One patient had been a smoker for fifty years. He had seen one case of late recovery with imperfect vision and persistent pallor. He had never met with a second attack. In a diabetic a very small quantity of tobacco would give rise to it.—Mr. CRITCHETT mentioned the case of a youth who from sixteen to eighteen years of age smoked half an ounce daily. The symptoms were very marked, but complete abstention from tobacco brought about his recovery in three months.—Dr. LITTLE referred to a case of amblyopia from bisulphide of carbon. The patient had been employed in the curing room of some rubber works for three months, when he found his sight failing, and three months later he had extreme failure of vision. The optic discs were pale and hazy; the vessels narrowed; the fields for white and blue contracted, those for red and green absent; smell and taste were numbed, and hearing was affected on one side. A year later, after abstention from his work, he had almost normal vision. In another case there was normal vision and no scotoma, but all the fields were contracted. He also recovered.—Mr. POWER thought that there was still much to be made out by inquiry. He thought that tobacco did not produce these poisonous effects until digestive disorders and anæmia were already established. Many conditions had to be thought of, and he mentioned a case where a searching inquiry brought to light an attack of typhoid fever, as well as a history of excessive drinking and syphilis. He thought that strychnine and iron were of very great advantage in these cases.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE ninth and last meeting of the second session of this society was held on June 22nd, Dr. Samuel Sloan, President, in the chair.

Dr. JOHN WILSON (Hillhead) communicated a paper, accompanied by diagrams, on the Best Mode of assisting at the Outlet the after-coming Head. The paper was read and

Digitized by Google

commented on by the SECRETARY (Dr. Turner).—Dr. PARK then read a paper on the Scientific Dilatation of the Os and Cervix Uteri and Intra-uterine Therapeutics. He advocated the use of the "artificial amnion" invented by Mr. Taylor of Birmingham as being superior to all other dilators in principle and detail. He laid special stress on the fact that the natural method of dilatation was closely followed, being effected really *ab intra*, and not *ab extra*. He also stated that it was more adapted for general use than Barnes' bags, as there was not so much necessity for preliminary dilatation by tents. One introduction through the os and cervix was sufficient, thus avoiding the irksomeness of instruments depending upon the principle of repeated introduction of sounds of larger and larger calibre. There was no solution of continuity of the lining mucous membrane involved, as was almost necessarily the case where dilators acting on the principle of leverage were employed. Passing to the question of intra-uterine therapeutics, he asked the Society if they did not think that the present-day neglect of and fear of intra-uterine medication was being carried too far. He pointed out that we are in the position now of having a great many more remedial agents at our command than we had even ten years ago, and instanced hazeline, resorcinol, cocaine, glycerine, iodoform dissolved in euc. extract, iodol, &c., as remedies which, alone or variously combined, might be used with perfect safety with Braune's syringe.—Dr. W. L. REID doubted whether the use of even antiseptic sponge tents was safe. He had seen two cases of septicæmia clearly traced to their use. He thought the smaller-sized Barnes' bag quite equal to Taylor's instrument. Twenty years ago many cases had been related of injury due to uterine injections, and he thought Dr. Park scarcely seemed to appreciate wherein the true danger lay—viz., in the accumulation of secretion in the uterus, and the contraction of the latter on its contents, with a closed os. He thought not much nitric acid could reach the fundus when administered on a naked probe and not through a cannula. He narrated the means taken by him to reach the interior of a womb the subject of sarcoma, and where the vagina was narrow by reason of senile atrophy. He first dilated the latter by the use of a large Barnes' bag, and was thus able readily to reach the os and dilate it by means of his own screw dilator.—Dr. SLOAN objected to the statement that mechanical dilators were not adapted for general use, and thought sponge tents dangerous.

Reviews and Notices of Books.

Diseases of Women. By Dr. F. WINCKEL. Translated by J. H. WILLIAMSON, M.D. With an Introduction by THROPHILUS PARVIN, M.D. Edinburgh: Young J. Pentland.

THIS book is described as a manual for students and physicians, and in many respects is very good. It is divided into seven sections, each section treating of the anomalies and diseases of some portion of the genital organs. These are the anomalies and diseases of the external sexual organs; of the vagina; of the uterus; of the Fallopian tubes; of the ovaries; of the uterine ligaments, peritoneum, and pelvic connective tissue; and of the breasts. Each section is divided into chapters, in which are discussed the various deformities and diseases to which the subject of the section is liable. This arrangement of the matter of the book is from a scientific point of view perhaps perfect, but from a clinical aspect it has its disadvantages. The physician, already acquainted with the diseases of women, will feel these disadvantages less than the student who is beginning his study. The first two hundred pages are occupied with the anomalies and diseases of the external sexual organs, and many subjects are discussed in this portion of the volume which are not usually referred to in English text-books. This part of the work is very well done. The third section consists of nearly three hundred pages, and deals with the anomalies and diseases of the uterus. The malformations of this organ are well described in the first chapter of the section. The second treats of the changes in the form and position of the uterus. Naturally, it begins with a discussion of the normal shape and position of the organ, and the author arrives at the conclusion that "it is a movable organ, every breath, every word and action, every variation in the fulness of the rectum and bladder influencing its position. It can, therefore, become abnormal only when the normal mobility of the organ is checked, lessened, or abolished in any given direction—i.e., when the organ is held in a fixed position." It necessarily follows from this definition of the normal position of the uterus, that all displacements of it are only signs of some other disease and not the disease itself. Displacements are classified as follows: (1) Elevation, descent, and prolapsus of the uterus; (2) ante, retro, dextro, and sinistro position; (3) anteversion and flexion, retroversion and flexion, dextroversion and flexion, sinistroversion and flexion; (4) torsion; (5) inversion; (6) herniæ. It is evident to all pathologists, "uterine" and others, that many of the above displacements are simply the results of disease in the immediate neighbourhood of the uterus, and have in themselves no pathological significance. A pretty full account is given of descent and prolapse of the uterus and its treatment. When we come to the chapters on versions and flexions we meet with a curious state of things. "Anteflexion is the normal condition of the virgin and nulliparous uterus, as anteversion is in the parous woman." And these become pathological only when they are permanent. Pathological anteversion and anteflexion usually result from diseased processes external to the uterus, such as peri- and para-metritis. The symptoms are said to depend upon the inflammatory condition coexisting with the flexion. Anteflexion causes no obstruction to menstruation or to impregnation. Yet the author recommends active treatment of various kinds, including stem pessaries.

In discussing retroflexion and version the author does not fall into such inconsistencies. Throughout he treats each as a disease calling for treatment. He discusses the causes of it and the anatomical changes in the uterine walls, and finds the latter to be elongation and thinning of the anterior wall of the uterus, but never thinning of the posterior wall at the angle of flexion. We meet with some extraordinary statements in this chapter. "The hyperæmia, erosions, and ulcerations cause great sensitiveness of the uterine walls, so that many patients will notice every movement of the uterus. Very intelligent patients have attributed the sensation to the movements of a child or some animal, as a tapeworm." What are the sensations due to the movements of a tapeworm? According to Winckel, retroflexion causes anæmia, migraine, hysteria, insanity, and suicide. "In every case therefore," he says, "of general nervousness, hysteria, or chlorosis, a thorough examination of the pelvic organs must be made, and, as Schultze has said, the same course should be taken with patients who are sent to asylums for nervous or mental diseases." If symptoms of displacement have already appeared, young girls should be made to understand the necessity of genital exploration. Perimetric adhesions are to be torn through by manipulation, and pessaries of various kinds should be used; but our author draws the line at laparotomy and Alexander's operation. With regard to the latter, he says "the results hitherto published are by no means favourable, not even encouraging." We know no work in which more incorrect views are inculcated with regard to displacements—views the fallacious character of which has been placed beyond doubt by the works of Herman and Videler, works to which Winckel makes no reference.

In the treatment of inversion Dr. Winckel recommends manual attempts at reposition; and should these fail, the use of the colpeurynter and laparotomy as a final resort when all other means have proved unsuccessful. He disapproves of continuous elastic pressure on the fundus by means of a

Digitized by Google

cup and stem, and says: "He who has laboured for years with such a case has recognised the pressure which the inverted uterus will withstand, and will condemn as unreliable and dangerous all the sound-shaped instruments with knob, plate, or cup-like attachments, because they act upon too small a portion of the inverted body, and slip far too readily from its smooth surface." It is impossible to accept such a conclusion in face of the many old and chronic cases of several years' standing which have been successfully treated by this means.

The chapter on neoplasms of the uterus is worthy of careful study. Winckel regards öophorectomy for fibroids as still *sub judice*. He says: "The mortality is over 15 per cent., and the desired result fails in 20 per cent. of those cases not immediately fatal. The value of castration for unoperative (*sic*) uterine myomata therefore remains *sub judice*, and its value, when compared with myomotomy, cannot be definitely determined with our present limited experience."

The fourth section treats of the diseases of the Fallopian tubes, and the fifth of those of the ovaries. The little that is known of the diseases of the tubes is carefully summarised. The section on diseases of the ovaries is good. In this section the operation of spaying is discussed. The author thinks that the cases requiring this operation are rare, and that the operation frequently fails of the desired object. He considers every castration for the removal of ovaries which are not obviously diseased to be a blunder, and believes that cases in which spaying is frequently recommended recover without operative procedure. In this we heartily agree with him. "It is to be hoped," he writes, "that the time is not far distant when the extirpation of the healthy ovary for dysmenorrhœa, ovarian neuralgia, epilepsy, and mental diseases will be classed with clitoridectomy, once so frequently done, although the latter is far less injurious and harmless." The work is on the whole excellent, and will prove very valuable to the gynæcologist, though not so well suited for the beginner.

A Text-book of Pharmacology, Therapeutics, and Materia Medica. By T. LAUDER BRUNTON, M.D., &c. Third Edition. London: Macmillan and Co. 1887.

ALTHOUGH the interest of this new edition of Dr. Lauder Brunton's valuable work centres primarily in his long-promised vindication of his position with regard to homœopathy, it needs but a cursory inspection to prove that he has not thrown away his energies in his trenchant remarks in the preface. His explanation really occupies a comparatively small space; and as we have already dealt with it, any further reference is now unnecessary. In spite of judicious condensations and omissions, the amount of new material for which space was imperatively demanded has increased the size of the book by more than 100 pages since the first edition. In these additions Dr. Lauder Brunton utilises all the more recent facts concerning new remedies and new experimental methods of research; indeed, in applying his critical powers to his own work, he has discovered many opportunities of adding fresh touches to a book which was so well up to date in its last edition as to seem to call for little improvement. Not content with the record of the past, our author furnishes us with numerous prophetic glances into the future of materia medica and therapeutics; he believes that this lies in the wholesale substitution of artificially prepared compounds, of known composition and constant strength, for the far too numerous remedies at present derived directly from the vegetable kingdom—remedies whose constituents and properties are liable to extreme variations from accidental causes. While there is much to be said in favour of some such change, it may well be doubted whether it will bring much satisfaction to medical students—the names and chemical compositions of most new remedies of this type at present being sufficiently appalling, even if not actually misleading; many such drugs are now named according to the symptoms presumably calling for their employment; it can hardly be doubted that some, at least, of these names will eventually prove as evanescent as the term *officinalis* of the older botanical system. That this future, which will so largely revolutionise our studies, is not yet imminent we may gather from the number of new compounds proposed for employment being largely in excess of the number of new therapeutic successes which have been conclusively established. In the meantime, however, due recognition and appreciation must be accorded to Dr. Brunton's honest endeavour to build up a system of scientific therapeutics based upon the results of pharmacological research, and to substitute this for the dreary waste of power formerly expended over mere catalogues of botanical terms.

It is interesting to note that Dr. Brunton promises a small text-book on the connexion between chemical constitution and physiological action—a subject which, from the results of investigations with methyl and ethyl derivatives, appears likely to furnish important indications for therapeutic changes.

The Index of Diseases and Remedies still fails to produce perfect satisfaction, being avowedly little more than a "list of drugs which have been recommended by somebody or other at some time or other in the treatment of certain diseases," and thus it indicates rather what *has been* done than what *should be* done when dealing with any particular symptom or disease.

Several new diagrams have been added to elucidate the text, and on every page are to be found evidences of care in compilation and revision. As a valuable storehouse of pharmacological methods, bristling with suggestions for fresh researches, this book still worthily maintains the unique position assumed by the first edition.

A Treatise on Diseases of the Skin, with special reference to their Diagnosis and Treatment, including an Analysis of 11,000 consecutive Cases. By T. MCCALL ANDERSON, Professor of Clinical Medicine in the University of Glasgow. With plates and numerous other illustrations. London: Charles Griffin and Co. 1887.

PROFESSOR MCCALL ANDERSON has long been known as an authority on diseases of the skin, which he has had unusual opportunities of observing for upwards of a quarter of a century, and various monographs and papers which he has written from time to time on the subject have been much appreciated. The author decided—and, we think, not unwisely—to omit an account of the anatomy of the normal skin, which can be easily studied elsewhere. His main aim has been to make the work a reliable guide to diagnosis and treatment. There are numerous excellent formulæ on each page devoted to treatment, and under Diagnosis diseases liable to be confounded with one another are compared in parallel columns. The space devoted to the anatomy of the lesions is exceedingly limited, except where a discussion of the matter is of practical value. Eczema has a hundred and ten pages devoted to it, or more than one-sixth of the book, and seventy-three of these pages are given to treatment. With his main objects always in view, Professor Anderson's clear style and method are well displayed, and there is no doubt he has so far achieved a considerable success, and has produced a work likely to prove very acceptable to the busy practitioner. Personally, however, we cannot help feeling a certain disappointment, because, with a keen appreciation of Professor Anderson's special qualities and a knowledge of his opportunities and position as a teacher of clinical medicine, we sat down to the study of his work in the hope that we should find some masterly

...ons of disease, and both acute and practical dis-...s of some of the more interesting problems of the day ...field of skin diseases. It appears to us that, though ...t we get the result of his prolonged experience in dia-...and treatment, his multifarious engagements, the wide ...f his studies, and the limited nature of the task he ...nself, have prevented him from producing a work ...worthy of his reputation and capacity. The descrip-... of disease are mostly short, many by no means ...and hardly ever complete, though doubtless the ...s illustrative cases introduced in the text will ...eful. The chapter on erythema we do not like at ...e think it confused, and not abreast of our present ...ledge. Roseola annulata, or Erythema circinatum, is ... to be mostly a chronic affection occurring on the ... and back. Is Prof. Anderson not confounding it with ...chen circinatus of authors? We deprecate also his ...mendation of the retention of the term Lichen for ...r eczema. In another edition we hope the author ...ter fully into the description and treatment of that ... troublesome malady called Lichen urticatus. Prof. ...son has been ably assisted in the description of surgical ...ons by Dr. Hector Cameron, and by Dr. James Christie ... diseases of foreign climes. The views given in the ... on guinea-worm disease are not in accordance with ...test conclusions accepted by the late Dr. Cobbold and ... authorities. There are many important omissions and ...ents to which, if space permitted, we should like to ... attention; but in making these criticisms we do not ...ght of the great merits of the treatise in the somewhat ...d field the author has allowed himself to work in.

...re occurs in the treatise a serious printer's error, to ... Prof. Anderson directs attention in a letter which we publish in another column.

ABSTRACT OF THE

REPORT OF THE COMMITTEE OF INQUIRY INTO M. PASTEUR'S TREATMENT OF HYDROPHOBIA.

THE report of the committee nominated by the President ... Local Government Board in April, 1886, to inquire ... Pasteur's treatment of hydrophobia, was presented ... Parliament on Monday last.

...report commences by stating that it was found neces-...that some of the members of the committee should, ...er with Mr. Victor Horsley, the secretary, visit Paris ... obtain information from M. Pasteur himself, to ... his method of treatment, and investigate a con-...le number of cases of persons inoculated by ...and, further, that a careful series of experiments ... be made by Mr. Horsley on the effects of such ... on the lower animals. Mr. Horsley's experi-... tended to entirely confirm M. Pasteur's discovery ...thod by which animals may be protected from the ...fection of rabies. If a dog, rabbit, or other animal be ...bitten by a rabid dog and die of rabies, a substance can be ...obtained from its spinal cord which, being inoculated into ...a healthy dog or other animal, will produce rabies similar ...to that which would have followed directly from the bite of ...a rabid animal, or differing only in that the period of in-...cubation between the inoculation and the appearance of the ...characteristic symptoms of rabies may be altered. The ...rabies thus transmitted by inoculation may, by similar ...inoculations, be transmitted through a succession of rabbits ...with marked increase of intensity. But the virus in ...the spinal cord of rabbits that have died of inoculated ...rabies may be gradually attenuated by drying the cords, so ...that after a certain number of days' drying it may be injected ...into healthy rabbits or other animals without any danger of ...producing rabies; and by using on each successive day the ...virus dried during a period shorter than that used on the previous day an animal may be made almost certainly secure against rabies, whether from a bite or from any method of subcutaneous inoculation; and this protection is proved by the fact that if animals so protected and others not thus protected be bitten by the same rabid animal, none of the first set will die of rabies, and, with rare exceptions, all of the second set will succumb.

It may hence be deemed certain that M. Pasteur has discovered a method of protection from rabies comparable with that which vaccination affords against infection from small-pox. It would be difficult to over-estimate the importance of the discovery, whether for its practical utility or for its application in general pathology. It shows a new method of inoculation, or, as M. Pasteur sometimes calls it, of vaccination, the like of which it may become possible to employ for protection of both men and domestic animals against others of the most intense kinds of virus. The duration of the immunity conferred by inoculation is not yet determined; but during the two years that have passed since it was first proved there have been no indications of its being limited. The preventive treatment adopted by M. Pasteur is based on the foregoing experience; but the determination of the success of the method is far from easy, owing to—(1) the difficulty of determining whether the bites were really those of rabid animals; (2) the probability of hydrophobia in persons bitten by dogs that were certainly rabid depending very much on the number and character of the bites, whether they were on exposed parts or parts protected by clothing; and in all cases in the amount of bleeding; (3) in all cases the probability of infection may be affected by speedy cauterising or excision of the wounded parts, or by various washings, or other methods of treatment; (4) the unequal danger of bites of different species of animals, and even of different dogs. In some groups of cases the percentage of deaths among persons bitten by dogs believed to have been rabid has been estimated at only 5 per cent., in others at 60 per cent.; and the mortality from the bites of rabid wolves has been variously estimated at from 35 to 90 per cent.

By the courtesy of M. Pasteur the committee were enabled to personally investigate ninety cases treated by him, these being mostly those which had been earliest treated, in which the periods since inoculation were longest, and living within reach in Paris, Lyons, and St. Etienne. Among the ninety cases there were twenty-four in which the patients were bitten on naked parts by undoubtedly rabid dogs, and the wounds were not cauterised or treated in any way likely to have prevented the action of the virus; there were thirty-one in which there was no clear evidence that the dog was rabid; others in which the bite had been inflicted through clothes. It is estimated, from experience of the results of bites in other cases, that had they not been inoculated, not less than eight among these ninety persons would have died. Not one of them has shown since the inoculation any signs of hydrophobia.

Since, in order to quiet fears, M. Pasteur has been obliged to inoculate many in whom there was no satisfactory evidence that the bite was that of a rabid animal, it might be unjust to estimate the total value of his treatment in the whole of his cases as being more than the rate of mortality observed in them compared with the lowest rate observed in any large number of cases not inoculated. This lowest rate may be taken at 5 per cent.; and, as between October, 1885, and the end of December, 1886, M. Pasteur inoculated 2682 persons (including 127 from this country), the mortality should have been 130. But at the end of 1886 the number of deaths was 31, including 7 bitten by wolves, in whom the symptoms of hydrophobia appeared while they were under treatment; in fact, the actual percentage mortality was between 1 and 1·2, showing, on the lowest estimate, the saving of not less than 100 lives. Of 233 persons bitten by animals in which rabies was proved, only 4 died. Without inoculation at least 40 would have died. Among 186 bitten on the head or face by animals in which rabies was proved, only 9 died, instead of at least 40. Of 48 bitten by rabid wolves, only 9 died, instead of nearly 30. Between the end of last December and the end of March M. Pasteur inoculated 509 persons bitten by animals proved to have been rabid; only 2 have died, one of these, bitten by a wolf a month before inoculation, dying after only three days' treatment. The committee think it therefore certain that the inoculations practised by M. Pasteur have prevented the occurrence of hydrophobia in a large proportion of those who, if they had not been so inoculated, would have died of

Digitized by Google

that disease. And his discovery shows that it may become possible to arrest by inoculation, even after infection, other diseases besides hydrophobia. His researches have also added very largely to the knowledge of the pathology of hydrophobia, and supplied a sure means of determining whether an animal which has died under suspicion of rabies was really affected with that disease or not.

The question whether the method itself entails risk to health or life is then discussed, the distinction between the ordinary method and the "intensive" method being pointed out. By the first method there is no evidence or probability of any danger to health at all; but after the intensive method, which is only practised in the most urgent cases, deaths have occurred which might possibly be attributed to the inoculations rather than to the original infection. Yet in the worst cases the intensive method is relatively more efficacious than the ordinary method, nor is the rate of mortality greater after the former method than after the latter. Certain cases, one of which is detailed, have, however, excited suspicion from the mode of death. The case related is that of a man bitten by a rabid cat at the Brown Institution, treated by M. Pasteur the next day by the intensive method, continued during twenty-four days, and dying about a month later with symptoms of acute ascending paralysis. The man was very intemperate, and had been exposed to chill while crossing the Channel on his return home. Mr. Horsley proved that his death was due to the virus of rabies, by using a portion of his spinal cord for the inoculation of rabbits and dogs, who died with characteristic signs of paralytic rabies such as usually occurs in rabbits. Yet it is by no means certain that the fatal issue in this and in other cases treated by the intensive method was not due to the original infection. M. Pasteur has, however, greatly modified this plan of treatment, which he employs in none but the most urgent cases.

The final paragraphs of the report, which embody practical suggestions, may be given *in extenso*:—

The consideration of the whole subject has naturally raised the question whether rabies and hydrophobia can be prevented in this country. If the protection by inoculation should prove permanent, the disease might be suppressed by thus inoculating all dogs; but it is not probable that such inoculation would be voluntarily adopted by all owners of dogs, or could be enforced on them. Police regulations would suffice if they could be rigidly enforced. But to make them effective it would be necessary (1) that they should order the destruction, under certain conditions, of all dogs having no owners and wandering in either town or country; (2) that the keeping of useless dogs should be discouraged by taxation or other means; (3) that the bringing of dogs from countries in which rabies is prevalent should be forbidden or subject to quarantine; (4) that in districts or countries in which rabies is prevalent the use of muzzles should be compulsory, and dogs out of doors, if not muzzled or led, should be taken by the police as "suspected." An exception might be made for sheep dogs and others while actually engaged in the purposes for which they are kept. There are examples sufficient to prove that by these or similar regulations rabies, and consequently hydrophobia, would be in this country "stamped out," or reduced to an amount very far less than has hitherto been known. If it be not thus reduced, it may be deemed certain that a large number of persons will, every year, require treatment by the method of M. Pasteur. The average annual number of deaths from hydrophobia during the ten years ending 1885 was, in all England, 43; in London alone, 8·5. If, as in the estimates used for judging the utility of that method of treatment, these numbers are taken as representing only 5 per cent. of the persons bitten, the preventive treatment will be required for 860 persons in all England; for 170 in London alone. For it will not be possible to say which among the whole number bitten are not in danger of hydrophobia, and the methods of prevention by cautery, excision, or other treatment, cannot be depended upon.

The report is furnished with an appendix containing (A) an abstract report of Mr. Horsley's experiments; (B) a report on persons in France examined by members of the committee, with a list of English persons treated at the Pasteur Institute from Jan. 1886 to Jan. 1887; and (C) on M. Pasteur's methods of preventive inoculation. The report is signed by James Paget (chairman), T. Lauder Brunton, George Fleming, Joseph Lister, Richard Quain, Henry E. Roscoe, J. Burdon Sanderson, and Victor Horsley (secretary).

THE HOSPITAL SUNDAY FUND.

THE following are the principal contributions which have been received by the Secretary of the Hospital Sunday Fund since the publication of our last list:—Camden Church, Camberwell, and Sunday-schools, £103; Christ Church, Gipsy-hill, £79; St. Bartholomew's, Sydenham, £92; Holy Trinity, Roehampton, £52; Holy Trinity, Lee, £59; St. Paul's, Knightsbridge, £451; All Saints', Camberwell, £60; St. Stephen's, South Dulwich, £147; St. Paul's, Onslow-square, £322; St. Mary's, Kilburn, £78; St. Michael's, Stockwell, £51; St. Michael's, Blackheath-park, £64; St. Paul's, South Hampstead, £104; Emmanuel Church, Maida-vale, £71; Christ Church, Hampstead, £164; St. James's, Holloway, £107; St. Augustine's, Highbury, £65; Christ Church, Chislehurst, £61; Chapel Royal, Savoy, £50; Church of the Annunciation, Chislehurst, £61; St. Margaret's, Westminster, £202; Bloomsbury Baptist Chapel and Mission, £54; All Saints', Ennismore-gardens (corrected), £362; St. Mark's, Hamilton-terrace, £295; Christ Church, Highbury, £113; St. Paul's Presbyterian Church, Westbourne-grove, £63; Hampstead Parish Church, £70; St. Stephen's, Ealing, £129; Christ Church, Marylebone, £52; St. Peter's, Dulwich Common, and St. Dunstan's, £51; St. James's, Kidbrook, £141; St. John's Presbyterian Church, Forest-hill, £87; Clapham Parish Church, £58; St. James's, Piccadilly, £132; Holy Trinity, Sydenham, £120; Brixton-hill Wesleyan Chapel and Schools, £79; St. Marylebone Presbyterian Church, £58; St. James's, Paddington, £189; Trinity Church, Marylebone, £84; Lewisham High-road Congregational Church, £57; St. Mary's, Boltons, £68; St. Gabriel's, Pimlico, £109; St. Mary's and St. John's Churches, Putney, £87; St. Luke's, Redcliffe-square, £51; St. George's, Tufnell-park, £68; Brunswick Chapel, Upper Berkeley-street, £101; Mrs. C. Buxton, £100; Holy Trinity, Tulse-hill, £53; St. Columba, Pont-street, £100; Allhallows, Upper Thames-street, £50; Christ Church, Hornsey, £84; Christ Church, North Brixton, £53; St. Saviour's, Paddington, £74; Greek Church, £84; Allhallows, London-Wall, £50; Kensington Congregational Chapel, £72; St. Paul's, Upper Norwood, £57; St. Mary Magdalene, Paddington, £63; St. George's, Bickley, £74; Regent-square Presbyterian Church (Dr. Dykes), £137; Clapham Congregational Church, £80; St. Jude's, East Brixton, £63; Streatham Parish Church, £68; St. Mary's, Balham, £73; St. Margaret's, Lee, £82; St. John's, Notting-hill, £98; Brompton Church, £421; St. Thomas's, Portman-square, £117; All Saints', Clapham-park, £55; "Delta" (a further), £200; John Smith, Esq. (a further), £50; Earl of Rosebery, £50; St. Mary's, Bryanston-square, £107; Holy Trinity, Upper Chelsea, £196; St. Paul's, New Beckenham, £116; St. Peter's, Bayswater, £124; St. Mary Aldermary, &c., £83; Holy Trinity, Paddington, £216; Union Chapel, Islington, £151; St. George's, Hanover-square, £154; All Saints', St. John's-wood, £68; St. Paul's, Camden-square, £71; St. Michael and All Angels, Paddington, £192; Anonymous, £100; Church of the Ascension, Balham, £53; St. Thomas's, Westbourne-grove, £74; All Souls', Langham-place, £89; Immanuel Church, Streatham-common, £80; Christ Church, Mayfair, £83; St. Barnabas, Pimlico, £64.

The total amount received by the Secretary of the Fund up to the time of our going to press is about £28,500.

CAMBRIDGE MEDICAL GRADUATES' CLUB. — The annual dinner of the Cambridge Medical Graduates' Club was held at the Hotel Victoria, Northumberland-avenue, on Wednesday, June 29th, Mr. Timothy Holmes occupied the chair. The club on the occasion entertained as its guests the President of the General Medical Council, the President of the Royal College of Surgeons of England, and the Directors-General of the Army and Navy Medical Departments. The members and their guests present at the dinner numbered fifty-three; later in the evening most of those present adjourned to the conversazione of the Royal College of Physicians. The Cambridge Club is in a very prosperous condition, and now numbers over 200 members.

THE LANCET.

LONDON: SATURDAY, JULY 2, 1887.

THE report of the Hydrophobia Committee has appeared at last, and, it must be confessed, its character supplies a sufficient reason for the delay that has occurred in its production. To consider the evidence that has been accumulated at the Pasteur Institute, and to form an opinion as to the alleged results, could not, indeed, have needed so long a time as a whole year; but to verify those results by independent investigation, to test the practical value of the inoculations as a means of preventing hydrophobia, must, it is evident, require a considerable time; and the Committee is to be congratulated on having attained a definite conclusion in the time they have taken.

The definite character of the conclusion reached will probably render the report a surprise to most members of the profession who have compared the divergent opinions that have been so freely expressed by men not ill qualified to judge, and have duly realised the difficulty of the investigation and the many sources of fallacy arising from the character of the facts themselves. It is certainly satisfactory that men so well able to weigh the evidence and to observe the facts, after having had the fullest opportunity of investigating the results obtained at the Pasteur Institute, should have come with one accord to an opinion so precise. Without doubt, their verdict is the most important yet pronounced upon the subject, and must go far to decide the question of the prophylactic value of the inoculations of PASTEUR.

The process itself was studied in Paris by three members of the Committee — Sir HENRY ROSCOE, Dr. BURDON SANDERSON, and Dr. LAUDER BRUNTON. A series of experiments were instituted after the return of these members by Professor VICTOR HORSLEY, while the other members of the Committee, Sir JAMES PAGET, Sir JOSEPH LISTER, Dr. QUAIN, and Dr. FLEMING, formed an opinion on the facts submitted to them. Those facts are fully stated in an appendix to the report, so that it will be possible for all persons who are interested in the subject to weigh the evidence and the conclusions. It can hardly be doubted that those who are competent to form an opinion will agree in the main with that expressed by the members of the Committee.

It must not be assumed that all parts of the report are of equal value. We have alluded to the sources of fallacy that lurk in the statistics of PASTEUR; the members of the Committee have taken due account of them, and have endeavoured as far as possible to avoid them. To eliminate them altogether is impossible, and the conclusions reached cannot have more than a very high degree of probability. But it is otherwise with the experiments instituted by the Committee: these are apparently free from all sources of error. They are not numerous, it is true, but their results are unequivocal, and seem to leave no room for doubt that the inoculation with the weakened virus of rabies confers an immunity from the disease. The inoculation with emulsion of the spinal cord of rabid rabbits preserved a series of dogs from rabies, although the most certain conceivable method of inoculation was employed—a bite from an animal in the acute stage of the disorder. In no case did the animal contract rabies, whereas of other unprotected animals bitten at the same time the majority contracted the disease. The experiments thus seem to leave no doubt of the efficiency of inoculation in rendering harmless a subsequent infection. They prove that the malady, as produced by the attenuated virus, is trifling, and they thus confirm two of the most important statements of PASTEUR. On the question whether inoculations, made after a bite has been inflicted by a rabid animal, confer the same immunity — a question of paramount importance — the original researches throw no direct light. But the confirmation of the conclusions of PASTEUR, in so far as they have been reinvestigated, is not without its significance, for it naturally increases the readiness to accept also those conclusions that have not been the subject of independent study. The statistics of PASTEUR have been subjected to a careful examination by the Committee, and the conclusion from the analysis is entirely in favour of PASTEUR'S method. A considerable number of cases were personally investigated, so far as investigation was possible after the lapse of a considerable time. The facts of these cases, the means employed to prevent infection—washing, cauterisation, &c.,—and the evidence as to the condition of the dog which bit the patients, are described in the appendix to the report. The conclusion drawn from these facts is that in many of the cases the dog was unquestionably rabid, and that a certain proportion of the sufferers would have died from hydrophobia if they had not been treated, and who, being treated, have not suffered from the disease. The conclusion that the method has saved a considerable number of lives, and that it is at present, and probably will be for long, the only mode of saving from death those who have been bitten by a rabid dog, affords strong support to PASTEUR'S conclusions, and, we need hardly say, must have most important practical results.

Nor is this all. By the opponents of PASTEUR it has been alleged that the dangers of his inoculation are scarcely less than those of the bites of rabid animals. It has been stated that many deaths have occurred in consequence of the treatment, and that some of the patients have actually been affected with paralytic rabies in consequence of the inoculations. On this point also the verdict is in favour of PASTEUR. It is, perhaps, doubtful whether this verdict rests on so firm a foundation as does that of the protective power of the treatment. The report confines itself to one of the cases of death after the treatment, the case of the man GOFFI, who was bitten at the Brown Institute and died in St. Thomas's Hospital. On this case the report throws a new and startling light. It will be remembered that the cause of death was spinal paralysis, and its connexion with rabies was denied. Mr. HORSLEY proves that the disease was paralytic rabies; the results of inoculations make the fact unquestionable. The treatment was certainly unsuccessful, and it is suggested that almost continuous intoxication may have prevented its success. Was the malady due to the original infection or to the "preventive treatment?" The Committee suggest the former

Digitized by Google

as the probable cause, that paralytic rabies may be more common than is supposed, and that the disease known as acute ascending paralysis, or LANDRY'S paralysis, may be, often at least, paralytic rabies. If this conclusion be correct, it is strange that paralytic rabies should not be observed more frequently as the distinct sequel to the known bite of a rabid animal. It seems more probable that, if the death of GOFFI was the result of the bites he received, the form of the malady was determined by the influence of the inoculations. But the conclusion of the Committee seems to be that, although the strong virus formerly employed may have entailed some evil consequences, the method now employed is free from serious danger.

We have said that the report of the Committee can hardly fail to have important practical results. The Government has ordered the inquiry in response to a public demand, and, the verdict being so clear and strong, the establishment of a Pasteur Institution in this country seems now to be their clear duty. Whatever other effect the report may have, it will certainly compel increasing numbers of persons who have been bitten by dogs, rabid or not rabid, to seek what is said to be a certain safeguard against a terrible possibility. That they should have to go to a foreign country for the treatment, which the Government Committee consider some at least of the bitten persons will require, will be intolerable. The inevitable result of the report must surely be the establishment of a Pasteur Institute in this country, and after such an answer as the Government has received to its inquiries the task can scarcely be left to private benevolence.

THE movements in favour of granting degrees to London medical students are steadily being pressed forward, and some very important decisions in reference to them have recently been arrived at. The Colleges of Physicians and Surgeons have adopted the resolution of their delegates, declaring the inexpediency at present of holding any conference with the Councils of University and King's Colleges for the purpose of procuring powers to grant degrees in Arts and Sciences, and their decision to proceed conjointly, and independently of other bodies, with their endeavour to obtain the right to confer degrees in Medicine and Surgery. The delegates of the Royal Colleges have also submitted for approval drafts of a petition and Charter, and these, having also been passed by the Fellows of the College of Physicians and the Council of the College of Surgeons, will at once be laid before the QUEEN in Council. By the Charter, which is published in another column, power is sought to form a governing body of forty-eight persons—twenty-four from each College—to be called the Senate of Physicians and Surgeons, to whom shall be entrusted the framing of the necessary regulations and the authority to see that such regulations are complied with. The Council of the College of Surgeons is composed of twenty-four members, and these will, as elected, become the representatives of that College on the Senate, whilst twenty-four Fellows of the College of Physicians are to be chosen, three of them to go out of office annually, but to be eligible for re-election. We cannot but think that this eligibility for re-election is a mistake, for it will allow only a minimum of change, and the Senate will practically become a permanent body, devoid of a sufficient number of young members to enable it to readily adapt itself to changes in teaching and examination. An error similar to that committed by the founders of the University of London should have been avoided. The President of the Senate will hold office for two years, and will be in succession the President of the College of Physicians and of Surgeons respectively, whilst two Vice-Presidents will be elected annually from among the members of the Senate. Twelve members are necessary to form a quorum and the vote of the majority present is to be decisive. The degrees in Medicine and Surgery are to be conferred on any person who, "by passing the examinations formerly held by both of the Colleges separately, or by passing the examination held by the Examining Board of the two Colleges, or by passing any other examinations to be held by the two Colleges jointly or separately, has already acquired, or may hereafter acquire, the qualifications for registration under the Medical Act, and who shall have also complied with such further regulations (if any), or undergone such further examination (if any), as the Senate may from time to time see fit to impose or require." The past Licentiates of the College of Physicians and Members of the College of Surgeons will by this clause be placed on exactly the same footing as those who qualify in the future, and this just and far-reaching provision will secure a wide amount of sympathy among the members of the profession in favour of the movement. The questions of an additional examination or examinations and of a title are left open for future discussion, and are therefore omitted from the Charter.

The refusal to confer with University and King's Colleges has compelled those bodies to take separate action, and they will have the full support of the Association for promoting a Teaching University in London. The Councils of these Colleges have now agreed on asking for a joint Charter to found a new university in London on the lines of the Victoria University in Manchester, with power to confer degrees in Arts, Science, and Medicine. Every student must have pursued a course of study in a college in the university, and, for medical study, the other medical schools of London are to be included. A Teaching University, such as exists in Scotland and in the north of England, would then be available for London students. The discussion as to the advisability of applying for such a Charter led to the resignation from the Council of University College of those members who were most closely identified with the University of London, but these vacancies have now been filled up. Mr. ERICHSEN takes the place of the Earl of KIMBERLEY, and Sir R. N. FOWLER that of Sir JULIAN GOLDSMID; while Sir U. J. KAY-SHUTTLEWORTH, Dr. RUSSELL REYNOLDS, Messrs. BENSON, DIGBY, and ROMANES have become members of the Council. The application for a Charter will be at once made, so that the advisers of the QUEEN in Council will have the two requests before them at the same time. The division among the old members of the Council of University College evidently points to an active opposition by the supporters of the existing university to the formation of a new Teaching University, and this movement is in most danger from this quarter. The universities, as a body, the other professional corporations, and the provincial medical schools

Digitized by Google

will all oppose the granting of a Charter which shall give the power of conferring degrees in Medicine and Surgery to the Royal Colleges of Physicians and Surgeons. As this opposition is based on various grounds, some of which are just and tenable, whilst others are merely selfish, we must again advise the appointment of a Royal Commission before whom the arguments for and against this shall be fairly urged and weighed, and this should be appointed at an early date.

THE *Spectator* has recently published a kindly article on the uses of medical etiquette and the amenities which regulate the profession, based on the recent judgment of Lords COLERIDGE and DENMAN, that the medical attendance purely by an unqualified assistant cannot be legally charged for. Our contemporary points out that English law very characteristically provides, not that men shall not take the advice of the unqualified, nor, as in other States, that the unqualified shall be prohibited from giving it, but only that such advice shall have no legal value. He thinks that this disadvantage or disability is fairly efficient. Ignorant and unqualified practitioners are a foil which sets off rational and scientific medicine. Their very ignorance may occasionally make a slight success for them easier than for an educated man, as Sir JAMES PAGET charitably thinks is the case with the bone-setters in exceptional cases. Such an admission is the very cream of charity, and must not be abused by being treated as an admission that generally ignorance is an advantage. The achievements of ignorance in the bone-setting line, taken as a whole, are a fraud, and sometimes a tragedy. It is gratifying to read in our contemporary such a vindication of the customs of professional modesty and etiquette, which do not permit medical men to forget that they are gentlemen, and which prohibit advertising, the disparagement of brother medical men, and all vulgar methods of attracting attention or seeking patients. In these days when some newspapers that ought to know better are ready to cater for those who forget such rules, and to receive money for their advertisements, it is pleasant to have to thank a contemporary for putting a just estimate on medical etiquette, which in the long run benefits the public quite as much as the profession. The *Spectator* dwells on the unseemly and injurious consequences that would result if the strict rules of professional ethics were relaxed, and medical men were permitted to imitate quacks in their boasting and advertising methods. "Given," it says, "keen competition and no moral restraints on a man's power to push himself by advertisement, and we should of necessity have the disgusting spectacle of men bidding against each other in order to relieve human suffering and to save life." This disgusting spectacle is, alas! occasionally seen, in spite of the rules of Colleges and the great unwritten law of the profession against such practices. The offenders chiefly from too great numbers in the profession occasionally appear painfully in practices at which they would have blushed. We do not think a qualified medical man distributes a circular through his neighbourhood without a feeling of the compulsion of want. However painful to say that such practices [illegible] shock in the ordinary professional mind, and to bring censure and discredit on those who resort to them. Even the Colleges occasionally still exercise their power and discharge their duty in punishing those who do so. It would be a great support to them if our lay contemporaries would imitate the *Spectator*, and expound to the public the value of a code of rules which excludes the arts of trade and the methods of business. We have no wish to restrict the liberty of patients. Patients have a right to consult whom they please, and to change their medical advisers if they see fit to do so, but they will make a woful use of their liberty if they forget the essential difference between a profession and a trade, or expect from their medical man the airs and arts of a tradesman, and change one who despises such arts for one who uses them. Medicine is not a profession that can be so used with advantage: but the very opposite. The best members of the profession best know that medicine has its limits; it cannot achieve the impossible or cure the incurable. Where pretence and boasting and disparagement of others begin, science ends. Men who are suffering from grave diseases, and are not all at once relieved, are apt to give ear to those who will promise immediate cures. They cannot be severely blamed if they do. But it is otherwise with the medical man who takes advantage of those who are willing to believe the impossible. The man who takes advantage of suffering to delude it and to profit by it is amongst the meanest of men, and it will be a bad day for the profession and a worse one for the public if the Colleges and the Medical Council ever cease to regard such men as guilty of conduct disgraceful in a professional respect.

The very progress of medicine, and its tendency to subdivision into specialties, render the preservation of its code of morals more important than ever. The public is helplessly at the mercy of its medical advisers, who have to report on facts of which the patients can often know nothing. The refinements of diagnosis, and the growing sensitiveness of the race under highly artificial conditions of existence, make honesty and perfect moral simplicity in the doctor qualities of prime value. Such qualities were prized in the time of HIPPOCRATES, whose great rules of professional life require medical men to practise their art with modesty, and to treat the sick with consideration and their brethren with respect. *A fortiori*, they are needed now.

THERE are but few aspects of the remarkable progress which has characterised the fifty years' reign of our Sovereign upon which we can look back with greater satisfaction than that which is identified with the influence of preventive medicine on the health of the public. Whether regarded from the scientific or the administrative point of view, the benefits which have accrued to the population of this country must be held to have been immense, and they are indicated alike in the lessening of mortality, in the increase of health and comfort, and in the diminution of the misery which so invariably follows on the prevalence of preventable disease. When the QUEEN first came to the throne there was no general system of registration of death and its causes; small-pox, typhus and other continued fevers, scarlet fever, cholera, and other epidemic diseases, were all but uncontrolled; except for the

Digitized by Google

partial acceptance of the protection against small-pox which had followed on the great discovery of JENNER, there was no organised method of dealing with infectious disease, and even intelligent people were inclined to look to the heavens above and to the earth beneath, and to talk of meteoric and telluric influences, in seeking an explanation of epidemics. All this is now changed; we know that the diseases in question are essentially preventable, and a host of ardent workers are labouring in their various departments to control those elements of disease which heretofore wrought unrestrained mischief among the people. Step by step the country has been educated to appreciate the advantages of health; and as the lesson has been learnt, whether as the result of the labours of past or present teachers, or of prevalences of disease such as the cholera epidemics which occurred between 1849 and 1866, the laws of health have been embodied in statutes, a central health authority has been established, and every district throughout the country has been provided with an officer who is locally regarded as fitted to impart to others the information he possesses in that branch of medicine which deals with the prevention of disease.

Nowhere has the change been more marked than in regard to town life. Our cholera epidemics fastened upon the crowded courts and alleys where water, drainage, and all sanitary surroundings were foul; typhus settled itself firmly in those portions of our cities where there was dense overcrowding of houses on area and of people in houses, and where unventilated, dark, and unhealthy cellar dwellings abounded. As soon as these facts were appreciated, the remedy was applied on a scale which is wellnigh astounding; for, grumble as we may at the need for more rapid progress, it should not be forgotten that during the past ten years alone some sixty millions sterling have been raised for purposes essentially sanitary in their character. Unwholesome dwellings have been swept away by the thousand, filth-sodden towns have been sewered and have been provided with water from sources no longer open to suspicion of pollution, and house drainage has been improved on the widest scale. It is difficult to set out precisely what has been the effect of all these measures. But, taking continued "fever" as a type of that class of disease which is eminently controllable by such measures, we find that, whereas in the five years 1851-55 the death-rate per million living from that group of affections was 995, it has almost continuously fallen, until it is now but little over 290. Here alone the saving of life has been immense.

The promotion of vaccination by a State organisation has also had a remarkable effect upon small-pox. When Her Majesty's reign began, people were still dying of small-pox at the rate of nearly 60 per 100,000 per annum; now, and this in spite of ill-advised and ignorant attempts to prevent the general acceptance of vaccination as a preventive of that disease, small-pox only kills a tenth part of those who formerly fell victims to it. With measures of compulsory notification of infectious diseases, the provision of hospitals for the isolation of the sick, and regulations as to attendance at State-aided schools, great efforts are being made to control diseases, such as measles, scarlatina, and diphtheria, which still cause lamentable mortality amongst our infantile population. And as regards imported diseases, such as cholera, the nation, abandoning its trust in antiquated methods, such as quarantine, trusts more and more to the removal from our midst of those conditions which enable such infections to obtain a footing amongst us.

Much of the work which has led to these several administrative changes has been brought about by the medical department of the State under the guidance of its first and its present medical heads. But the labours of that department have by no means been confined to the perfecting of administrative measures. Scientific and skilled research has gone hand-in-hand with such work, and the results obtained have, as a matter of fact, formed the basis and ground of the administrative advice tendered. The prosecution of sanitary science in England has achieved some great successes. The discovery of the relation between soil-wetness and death from phthisis which was made over twenty years ago by Dr. BUCHANAN, the masterly work of Dr. BALLARD in searching out the connexion between milk and enteric fever in Islington in 1870, and the recent discovery by Mr. POWER and Dr. KLEIN of the connexion between scarlet fever in the human subject and the use of milk from specifically diseased cows, are instances of the sort of work which has made a permanent mark in the history of our sanitary progress. And a host of others have been sedulously labouring in allied directions; the study of micro-organisms and their connexion with infectious diseases having especially enlisted a number of workers, and having already done much to elucidate the question of the origin of infection.

We may, without undue boasting, confidently assert that nowhere has sanitary science made such progress as in this kingdom, and nowhere has a State been served by a body of workers more skilled or untiring. And yet on an occasion when the State had a remarkable opportunity publicly to recognise those who have served their country with merit and distinction, although it must afford universal gratification that a past master in the science of sanitation, Sir JOHN SIMON, has received the well-deserved honour of K.C.B., no member of our profession at present engaged in the active work of preventive medicine has received recognition by the bestowal of a titular honour.

THE College of Physicians is unable to determine whether leprosy is contagious or not. Those who believe that the exhaustive inquiry, in which the late Dr. GAVIN MILROY took so prominent and important a share, conducted by the College twenty years ago, had definitely settled the point, may be surprised at the above statement. The report of the Leprosy Committee then stated:—

"The all but unanimous conviction of the most experienced observers in different parts of the world is quite opposed to the belief that leprosy is contagious or communicable by proximity or contact with the diseased. The evidence derived from the experience of the attendants in leper asylums is especially conclusive upon this point. The few instances that have been reported in a contrary sense either rest on imperfect observation, or they are recorded with so little attention to the necessary details as not to affect the above conclusion. That leprosy is rarely, if ever, transmissible by sexual intercourse, when one of the parties has no tendency whatever to the disease, is the opinion of the great majority of the respondents who have had the largest opportunities of observation."

Digitized by Google

Such a definite and well-founded opinion could not fail to carry weight with it; and there is no question that it did good service in helping to further dispel the ancient belief in contagion, a belief which had already largely died out. Nevertheless the question was not closed. In scientific circles it was decidedly reopened when HANSEN discovered in 1874 the bacillus lepræ—a discovery which has been repeatedly confirmed, and which has established the position of the disease in the same category as tubercle, syphilis, and glanders as an infective disease. But even this discovery does not of itself point to the disease being contagious in the ordinary sense, no more than the discovery of the tubercle bacillus established the contagiousness of phthisis. What it does do is to suggest the dependence of leprosy upon a specific virus, and the liability under certain conditions of its transmission from the sick to the healthy. Nor has the idea of contagion died out amongst those who are brought into daily contact with the disease. The circumstances which have reopened the question at the College of Physicians show this. A communication was addressed to the College by the Colonial Office, pointing out that very many medical men practising in the colonies were unable to assent to the views declared by the Leprosy Committee of the College that the disease is not contagious, and the Colonial Secretary desired to know whether the College still adhered to that opinion, and particularly whether measures for the isolation of lepers were justified. This communication was referred to a committee, who presented a report, which showed that the members of the committee were not unanimous in upholding the previous declaration of the College, and the report had to be drawn up in terms which left the question in a more ambiguous state than ever, although it affirmed definitely enough the reasonableness as well as the propriety of the foundation of State-aided leper asylums on grounds of humanity, quite apart from any doctrine of contagion.

The resolution arrived at by the College at the close of a rather desultory discussion was a right one, and perhaps under the circumstances unavoidable. It could not but be felt, in the light of the committee's report, that the subject of the contagiousness of leprosy was one which had not yet been finally determined; and having in 1867 investigated the subject so fully, the College of Physicians would have failed in a public duty if it had declined to renew its investigations with the added experience of twenty years. At the same time such an inquiry, to be effective, would be costly and prolonged. In the interest of the Colonial Empire it is desirable that the Government should furnish the funds to render the investigation a thorough one. It was thought a proper course to refer the report back to the committee, in order that a statement of the present position of the subject might be appended, together with the opinion of the desirability of a further investigation by the College under the ægis of the State.

We have already published the names of candidates for election to the Council of the College of Surgeons in the room of the retirement of certain of its members, and the desirability of electing only such candidates as are known to be in sympathy with the views of the constituency. We must express our regret only of the three retiring members of Council will not again come forward, and this one not by any means the senior of the three. Mr. WOOD, who does not seek re-election, doubtless has good reasons for retiring, and we must respect these reasons as valid. Sir SPENCER WELLS, who is coming forward for re-election, has made his mark as a surgeon; he has been twice elected to the Council, and has served the office of president. Surely he has had his share of office, and might now reasonably seek rest from his labours. It will scarcely, we imagine, be urged, even by his best friends, that his special knowledge of the affairs of the College or his administrative capacity is such that the Council would be seriously crippled by his retirement. Mr. HUTCHINSON is also seeking re-election. Besides being a most distinguished and many-sided man, he is in the full vigour of middle age; with him re-election presumably means nothing less than the presidency. We wish Mr. HUTCHINSON every success in his candidature, and the near realisation of his most natural and laudable ambition, the presidential chair, though this may not be accomplished until next year, as we believe there is a probability of the present President, Mr. SAVORY, being re-elected. As regards the other vacancies, no more fitting candidates could be found than Mr. COUPER and Mr. WILLETT. They possess the necessary knowledge of students and young practitioners, and are in sympathy with their aspirations and requirements. Moreover, they are men known for their advanced and liberal views on College matters; they have already given much thought and attention to what we may call "College politics," and would thus go to the Council with that knowledge (so few new members possess) which would fit them at once to deal with the questions that will come before the Council. Both Mr. COUPER and Mr. WILLETT are believed to be in general accord with the views put forth and approved by large majorities at the general meetings, and with which Mr. R. B. CARTER, another of the candidates for office, is notoriously not in accord, unless the events and reflections of the last six months have brought about changes in opinion which he has not yet had the opportunity of making public. The absence of provincial candidates is perhaps not unnatural at the present juncture. There are already four provincial Fellows in office, and many of the London Fellows (who form the staple of the voters under the existing rules of personal voting) think this a sufficiently liberal representation. By next year compulsory personal voting will probably have been abolished. We can hardly doubt that the relative proportion of town and provincial councillors will undergo marked changes within a short time, and that the provincial Fellows will secure for themselves more adequate representation than at present. Let us concern ourselves, however, with actualities—the coming election,—and seek to get the best men for our present purposes. Instead of seniors approaching the end of their career, with flagging interests, the Council ought to consist either of men engaged in teaching or in other ways in touch with students and their requirements, or of men from among the actual workers and toilers of the profession, personally conversant with the defects and deficiencies of the present professional organisation, and presumably, therefore, most competent to apply the remedies that may be needful for its improvement.

Annotations.

"Ne quid nimis."

THE HENLEY REGATTA AND THE NEW BYE-LAWS.

WHEN last week we spoke of the bye-laws drawn up to prevent the contamination of the Thames water by the house boats and steam launches, we complained that ever since last February they have been waiting the sanction of the Queen in Council. This sanction, we were informed, might be given in three days, three weeks, or three months. It seems, however, that we have not called public attention in vain to this grievance, for no sooner had we announced our intention of dealing fully with the question than somehow or another the procrastination of the authorities was overcome and the Royal sanction obtained. The new bye-laws are published in last Saturday's *Gazette*. This experience is very similar to what occurred last year. The Thames Conservators were fully aware that the congregation of so many house boats at Henley endangered the water supply of London. They had, we believe, even drawn up a project for bye-laws to meet this grievance, but it was not till our report on the contamination of the Thames at the Henley regatta appeared that a serious effort was made to bring the matter forward. The project was taken out of its pigeon-hole and advertised. This, as we have already explained, elicited protests and necessitated some modifications, and under these circumstances the Royal assent could scarcely have been obtained before the month of March. This would have been time enough to alter the drainage of the house boats for the present regatta. Nothing, however, was done. No pressure, apparently, was brought to bear, and the affair remained dormant till once more we took the matter in hand. No sooner was this known than, with marvellous celerity, the Queen's assent was procured, and the new bye-laws were published—this, too, in Jubilee week. To say the least of it, the coincidence is very striking, and we may fairly congratulate ourselves on having manifestly contributed to bring about an important sanitary reform. Unfortunately, the publication of the bye-laws in the *Gazette* at so late a date can really only serve to disarm criticism. A new law cannot be enforced in a couple of days; but the fact that the boats are now for the most part collected at one spot will render it easier for the authorities to convey to all whom it may concern knowledge of what is expected in respect to the new sanitary regulations. This, we trust, will be done with the utmost promptitude and rigour. It is monstrous that the house boats of wealthy people who congregate at Henley merely in the pursuit of pleasure should be allowed to drain direct into the water which the greater portion of the inhabitants of the metropolis are obliged to drink.

HOSPITAL MANAGEMENT.

AN excellent institution in the east of London, which has for the past twenty years done so much good work—we mean the East London Hospital for Children,—has unfortunately been disturbed by an incident which, however regrettable in itself, will, we trust, be not without good result. At the last general meeting of governors, held about a month ago, Mr. R. W. Parker, who personally has worked without ceasing on behalf of the institution, drew attention to the fact that many of the lay members of the Committee were conspicuous for their absence at the business meetings. He was confirmed in this by other speakers, notably by the late chairman, Mr. Charrington, who intimated that he would not have resigned office had the attendance been more satisfactory. An addendum to the motion for the adoption of the report, calling on the Board of Management to take early steps to rectify this defect, was moved by Mr. Parker, and carried by the meeting. This is only what should be. If gentlemen take office on a hospital board, they should perform the duties entailed by that office; but we fear it is too often the case for members of such boards to be content to leave the direction in the hands of a few. This is much to be deplored, for not only does it appear to show a lack of interest in the working of the institution, but it throws a burden of responsibility upon the small number who have already devoted much time and energy to the affairs of the hospital. Lay governors have their duties as much as members of the medical staff, and we cannot wonder that anyone who has the welfare of his hospital at heart, and who sees it languish from the apathy of those who ought to be most active in its maintenance should seize the opportunity to remedy the grievance. Mr. Parker, however, was not contented with this, and had the courage, we had almost said the temerity, to renew the charge of absenteeism when the subject of the re-election of the treasurer, Mr. E. S. Norris, M.P., came up. In this he did not receive the same measure of support, and it is to be regretted that Mr. Norris was not present himself. That gentleman has, however, thought it fitting to indite a letter to a local paper which for discourtesy is as marked a sample of its kind as may be met with. To speak of the "attack" being made upon him by "a certain Mr. Parker," whom he has "no hesitation in denominating as the 'firebrand' of our Committee," is, to say the least, uncalled for. The profession is well acquainted with Mr. Parker, who has built up a reputation from the results of his untiring devotion to his duties at this very hospital, and he can well afford to pass the matter over in silence. As regards Mr. Norris, we do not say that his office of treasurer should necessitate his constant attendance at the meetings of the Committee, and as he has been long attached to the hospital it might be ungracious to dispense with his services because his other public duties call him elsewhere. But it was quite within Mr. Parker's right, and that of any member of the governing body, to impugn a state of things which he conceived to be detrimental to the progress and welfare of the hospital. There must be in the management of the institution questions of finance constantly arising, in which the advice and opinion of the treasurer are requisite, and it passes our comprehension to see how any gentleman can hold an office of that kind without keeping himself personally acquainted with the working of the institution of which he is so prominent a member; and when, on his own showing, his time is so much occupied elsewhere and his interests so divided, how can this knowledge be sustained?

EPIDEMIC SUICIDE.

EPIDEMICS of suicide are happily very rare in this country. We are not as a people, though proverbially grumblers, particularly discontented with our lives. In nationalities distinguished by the enforcement of military service as part of the duty of citizenship, life is so irksome that suicides are common. We venture to think that the conditions of living have more to do with suicide than beliefs or fatalism. It would, however, be a mistake to confound the mere prevalence of suicide in a district or class with epidemic suicide propérly so-called. It is possible that just as hysterical phenomena may extend by imitation from one person to another until the total number of individuals affected is very large, so the impulse to self-destruction may be propagated, although there is no sufficient cause for the prevalence of the act. This would be an epidemic of suicide. It would be interesting to ascertain whether genuine evidence in support of the hypothesis that self-slaughter is sometimes epidemic actually exists.

IS SEWER AIR NOXIOUS?

IF there is one thing more than another of which sanitarians have hitherto felt sure, it is that the air of sewers is dangerous and sometimes deadly to human life. The faint, sickly odour is familiar to all of us, and have not most of us had examples of disease which to all appearance was directly due to the escape of sewer air into houses? We recall one instance which may be taken as typical. In a large London house, admirably built, and supplied with New River water, typhoid made its appearance in the nursery floor at the top of the house, and one of the children died. On inspection it was found that the ventilating pipe of a closet passed into and not through the roof, that the syphon trap was apt to get dry, and that sewer air was actually passing into the room where the children slept. Probably the majority of our readers could record similar experiences. It is true that objections have been raised to the theory, of which the most formidable is the alleged fact that men who spend a large part of their waking hours in sewers do not seem to suffer from it. To this the current answers are that the men are presumably strong and healthy, and, what is far more important, they are not exposed to the influence at night, when vitality is lowest. But now we are confronted by new experiments, too important to be ignored, which raise more serious doubts. At the request of a Select Parliamentary Committee which in 1886 was appointed to inquire into the drainage of the House, Professor Carnelley and Dr. Haldane of University College, Dundee, have made careful experiments upon the air of sewers. Their results were communicated to the Royal Society at its meeting on June 16th last, and they are certainly surprising. Examining it by various methods, they were unable to discover that it was much worse than the atmosphere outside, and in some respects it compared favourably with the air of close rooms. Comparing the air of the sewer with the air outside it at the same time, they found that the sewer air contained about twice as much carbonic acid and about three times as much organic matter as the fresh air, but much fewer micro-organisms. In small and ill-ventilated houses they found more carbonic acid, more organic matter, and far more micro-organisms than in the sewer air they examined; so that if these experiments were to be taken as final and conclusive, the inhabitants of a small room would improve their sanitary position by living in the atmosphere of a sewer. But of course the experiments are not conclusive, and the authors have done wisely in founding no sanitary conclusions upon them. They will even be dangerous if they lead anyone to regard with indifference the presence of what we must continue to consider as an insidious enemy. In regard to organic matter and micro-organisms, it is the quality and not the quantity which is of importance. A small quantity of strychnine is more dangerous than a large quantity of sugar, a single rattlesnake than a cartload of blind-worms, and yet both chemicals may be described as "organic matter," and both reptiles as "moving organisms." Our knowledge is as yet quite insufficient to enable us to judge of the quality of the organic matter, [illegible] which is present in sewer air, and we have [illegible] to believe that it varies enormously. We have [illegible] of evidence in support of the current [illegible] not lightly discard it. But at the same [illegible] thankful for any experiments as carefully [illegible] have been, for they are sure, sooner or [illegible] to our real knowledge. Moreover, we must [illegible] experience has brought into promi- [illegible] agent in the spread of disease which [illegible] namely, milk. It is of course [illegible] rate, of the outbreaks which [illegible] air may have been due to [illegible] but it is at least improbable that all can have originated in this way. In the fearful explosion of cholera at Newcastle-on-Tyne exceptional mortality was observed among those who lived close to open sewers or worked over the gully-holes of drains.

DR. THIRIAR ON THE TREATMENT OF FRACTURES OF THE FEMUR.

DR. THIRIAR, in an instructive clinical lecture to the Brussels medical students on the treatment of fractures of the thigh, pointed out the advantages of the telescope apparatus proposed and described by Professor Derobaix some seven years ago. This consists firstly of a starch bandage reaching from above the knee to the foot, provided with a stirrup and a cord, which passes over a pulley, and has a weight attached to the end in order to keep up constant extension; and secondly, of a femoro-pelvic starch bandage, which is applied two or three days after the first bandage, the upper part of which it covers so that the one may slide within the other in telescope fashion. When dry, the femoral portion is slit up. It can thus be opened and the seat of the fracture inspected at pleasure, and if necessary manipulated by the hands, while an assistant makes any required degree of traction on the leg. Afterwards it can be tightened up by straps and buckles with which it is provided, and the limb is then absolutely protected against all lateral or see-saw movements, while the patient can be moved as much as is necessary for purposes of cleanliness without endangering the rigidity of the fractured limb. By this means Dr. Thiriar believes better results can be obtained than by any other apparatus; and he publishes a list of thirty cases, in all but two of which there was either no shortening or so little that it did not amount to a quarter of an inch. In one of the two unsuccessful cases the patient was excessively unruly, and in the other no amount of manipulation appeared to reduce the deformity when first seen.

COMPULSORY VACCINATION.

THE President of the Local Government Board was questioned in the House of Commons last week as to whether he was aware that a house-to-house inquiry in sixty-five towns of England had shown that a large majority of the householders were opposed to compulsory vaccination, and whether the answers of those canvassed report 428 cases of death and 1996 cases of injury as due to vaccination. Mr. Ritchie, in his reply, stated that he was aware that a number of questions had been circulated by the Anti-vaccination Society, but he did not know how many persons had declined to fill up the forms, and he did not attribute any particular value to the answers received. The worthlessness of an inquiry conducted in this manner is obvious, and Mr. Ritchie acted wisely in disregarding such statements. Everyone knows that it is the habit of ignorant people, whose minds are poisoned by the statements of anti-vaccinationists, to attribute to vaccination every ailment from which a child may suffer subsequent to the operation. Thus, but a few days ago, we had experience of an outbreak of chicken-pox in a household, the cause of which was accepted by the inmates to be the previous vaccination of a baby a few days before these illnesses occurred. A further question which was raised, as to the deaths of 271 children which were registered in England and Wales as due to cow-pox and other effects of vaccination, gave Mr. Ritchie the opportunity of explaining that the children vaccinated during the period in which the deaths took place amounted to 3,800,000, and that he was informed by the Registrar-General that almost invariably in these cases of death some secondary cause was mentioned, and by far the

Digitized by Google

most common of these secondary causes was erysipelas. Assuming for one moment that the certificates supplied to the Registrar-General correctly represented that vaccination and its effects caused death, it is comforting to know that erysipelas can be prevented by due care in the performance of the operation and in the subsequent management of the child. The recently issued instructions of the Local Government Board will assist in this direction, and every operator should caution parents as to the necessity for guarding their children against the risk of infection of erysipelas, either by exposure to other persons suffering from this disease, or by want of cleanliness. It is matter for speculation how many of the 3,800,000 children would have died from small-pox if they had remained unvaccinated—certainly many thousands, for small-pox used to spread over the country every four or five years and destroy a large proportion of children born since the preceding epidemic. This terrible loss of life has been prevented by vaccination, and it behoves every medical man to save an operation so potent for good from the discredit which is cast upon it so long as any deaths can be held to be due to its performance.

THE DETENTION IN WORKHOUSE HOSPITALS OF PAUPERS SUFFERING FROM SYPHILIS.

THE proverbial uncertainty of the law has recently been illustrated in a very striking manner. In 1867 the Act known as the Poor-law Amendment Act was passed (30 and 31 Vict., cap. 106), and among its other provisions were the very important powers conferred by Sec. 22:—"When there shall be in any workhouse a poor person suffering from mental disease or from bodily disease of an infectious or contagious character, and the medical officer of such workhouse shall upon examination report in writing that such person is not in a proper state to leave the workhouse without danger to himself or others, the guardians may direct the master to detain such person therein." In 1871, just four years later, the Royal Commissioners appointed to inquire into the Contagious Diseases Acts, 1866 and 1869, issued their report. Among the Commissioners were some experienced members of the Bar, including the chairman (the late Mr. Wm. Nathaniel Massey) and Mr. G. W. Hastings; the secretary, Mr. John Armstrong, was also a barrister-at-law. In the 53rd section of their report, page 16, the Act above quoted is thus alluded to:—"We are advised that the 30 and 31 Vict., c. 106, s. 22, which provides for the compulsory detention in workhouses of persons afflicted with contagious disease, includes syphilis, and we therefore recommend that, wherever there is a certified hospital within the union, any pauper afflicted with such contagious disease shall be removed to such hospital." Both the section of the Act and of the Commissioners' report appear plain enough, and although many persons held individual opinions that the Act referred only to such diseases as were indisputably infectious or contagious, such as scarlet fever, typhus, small-pox, &c., still the interpretation of the Act as just given was acted upon, and, until lately, no doubt existed as to the lawfulness of detaining paupers with syphilis. But the guardians of the Portsea Union having recently raised the question, a letter has been forwarded to them from the Local Government Board which effectually repeals this compulsory power, the law being thus defined:—"The Board direct me to state that in accordance with the promise which the President made to the deputation, a case has since been submitted to the law officers of the Crown for their opinion as to the powers of guardians under Section 22 of the 30 and 31 Vict., cap. 106, to detain in the workhouse persons suffering from syphilis. The law officers have given as their opinion that the provision in this section with reference to the detention in workhouses of persons suffering from bodily disease of an infectious or contagious character does not apply to persons in the workhouse suffering from syphilis in a contagious form, whether or not they are known prostitutes. According, therefore, to this opinion, guardians have no power under the statute before mentioned to direct the detention in the workhouse of the persons referred to." The effect, of course, will be that prostitutes will leave the workhouse uncured whenever they may feel disposed to do so. There would appear to be some sort of fatality at present in the various circumstances which are all conducing to the spread of syphilis. The closing of all the Government Lock Hospitals, the proposal to close the Westmoreland Lock Hospital of Dublin, the temporary closing of the Liverpool Lock Hospital, and now the abrogation of the compulsory powers recently enforced in workhouses,—all these tend to one result, for which it is to be hoped the public will be fully prepared—viz., the appearance of syphilis in an almost epidemic form. The medical profession have given warnings again and again, which have, however, passed unheeded. Probably some sensational article will sooner or later appear in some daily London paper similar to that which appeared seventeen years ago respecting the "Wrens of the Curragh," and with a similar startling effect. Or possibly some peer of the realm may deem the subject worthy of notice, and may call attention to the subject. Might it be possible this session to pass a short Act conferring the requisite power upon all boards of guardians?

HAY FEVER.

A PAPER on the subject of hay fever was read by Dr. John Roe at the recent ninth annual session of the American Laryngological Association (*Boston Medical and Surgical Journal*, June 9th). It was based on a study of forty-two cases—twenty-six males and sixteen females,—and of this number thirty-five had been practically cured. The plan of treatment was to cauterise the sensitive areas of the nasal passages, which in all cases were found diseased. It was pointed out that the condition of the larynx, pharynx, and bronchi must not be overlooked, and that not infrequently enlarged tonsils will keep up irritation in the turbinated bones. Thirty-one of the patients suffered from asthma. The conclusions arrived at were as follows:—1. All cases of hay fever have the initiative lesion in a diseased condition of the tissues of the nasal fossa. 2. All diseases of these tissues induce in the ganglionic centres connected with them an abnormal activity, which is reflected to other organs. 3. The sensitive areas in the nose are not found in any particular portion of the cavity, nor are there any zones which when irritated produce always the same manifestations. 4. The direction in which the irritation is reflected is always in the line of least resistance. Irritation in the same region may be reflected in one direction at one time and in another direction at another time. 5. The disease in the nose may produce disease in other portions of the respiratory tract, which may become independent centres of irritation. 6. The affection recognised as hay fever is due to local irritations brought in contact with the sensitive areas in the nose. 7. The affection is not *per se* neurotic, nor is the so-called neurotic condition of the person necessary to render him susceptible to local irritation applied to the air-passages. It is not necessarily associated with the nervous temperament. 8. The neurotic condition, which is often regarded as the cause of the hay fever, is often the result of the local irritation. 9. By careful and thorough treatment of the disease of the nasal tissue, combined with that of other portions of the respiratory passages below, which have become secondary sources of irritation, we need not fail to cure hay fever. In the

Digitized by Google

discussion on the paper Dr. Sajous observed that he had often produced temporary benefit by the cautery, but attributed that to the fact that the cauterisation was too superficial. Since he had deeply cauterised he had cured the disease. Dr. Mackenzie of Baltimore did not think there was disease of the nose in hay fever, which he regarded as a neurosis, not to be cured by local treatment. Drs. Hooper and Solis Cohen agreed in the main with Dr. Mackenzie's view, the latter pointing out that the patients, besides being neurotic, were also often overworked, and had resorted to stimulants.

THE COMMITTEE ON THE ARMY AND NAVY ESTIMATES.

IN the examination of Mr. Knox, the Accountant-General to the War Office, before the Committee of the House of Commons, so far as we can learn from the imperfect newspaper reports, Colonel Nolan put a number of questions relative to the expense of the medical service, apparently with a view to get from Mr. Knox an opinion that the present system is expensive, and that the work might be done more cheaply. But the Accountant-General, while admitting the fact of the heavy expense, gave a very decided opinion that it could not be got rid of. The means of reduction at which Colonel Nolan pointed were the withdrawal of the right to retire after twenty years' service, and also an increase of pay after that period to induce officers to remain. But Mr. Knox, while admitting that this would be cheaper, did not believe it could be carried into practice. "The officers would not take it.....The medical profession desired the arrangement, and as the medical officers might not have been obtained, it was necessary to pay the price for the article." If the gallant Colonel will take the trouble to refer to the past history of the Medical Department, he may learn that the conditions of service to which he proposes to revert were those under which it came to a dead lock from want of candidates. No one who takes an interest in our soldiers would desire ever again to see the Medical Department brought to the deplorable condition from which it was raised by the reforms introduced by Lord Herbert, or even to that of a still later period (1878), when it was in so unsatisfactory a state that the Secretary of State for War deemed it necessary to suspend the usual advertisements for candidates, and to appoint a committee to inquire into the causes of discontent and report what measures were necessary to render the service once more popular (vide THE LANCET, Feb. 15th, 1879). But it may not be amiss to point out that, from the improved condition of the medical service, there has been a marked reduction in the sickness and mortality of the troops, which, totally apart from considerations of duty or humanity towards the soldier, implies a reduction of expenditure in replacing those who die and are invalided, and in the number of recruits required for that purpose. The latter, of itself, is a matter of importance at a period when it is necessary to raise upwards of 40,000 men annually to keep up the effective strength of the army That the medical service might be performed more cheaply as regards money expenditure we admit, but it would be at a serious cost to the country in the way of increased sickness and mortality and decreased efficiency. The experience of the late Egyptian campaign shows the position of the responsible head of the Army Medical Service to be one of great difficulty. The public cannot have forgotten the fierce attacks by the newspapers on the Department, because it had not provided trestle beds, whisks, mosquito curtains, cooking apparatus, medicines, and all sorts of medical comforts for an army disembarking at an unknown port, fighting a battle in the desert, and "rushing" the capital within a period of about three weeks. And now the financial reformers attack it on the score of the great expense involved in providing even the moderate, but necessary, supplies which were so decried. Surely our troops, called upon, as they are, to serve in all climates and often under circumstances very prejudicial to health, are entitled to thoroughly good and efficient medical and surgical aid, and this must be paid for. What appears to us to call for thorough investigation is the long list of general officers, the great expense of the military staff, and the state of the non-effective list of the combatant branches of the service. The commissariat, the transport, the military staff, and the very headquarters at the War Office, with its cumbrous staff of highly paid clerks, might all afford abundant materials for a judicious reduction of expenditure.

NASAL VERTIGO.

THE thesis might be maintained that irritation of any sensory area may give rise to vertigo; but the difficulty of proving to demonstration that such a proposition holds good would be very great. Hitherto the occurrence of vertigo as the result of a lesion in the nasal passages has not been generally accepted, and we doubt whether there can be any very special or causal connexion between a vertigo and a nasal lesion. In a few cases a connexion may be traced, but it is very possible that the nervous phenomenon, vertigo, is chiefly caused by the nerve weakness, the nasal lesion playing perhaps only the part of the "last straw." Dr. Joal, the latest writer on nasal vertigo, believing in its positive existence, asserts that the vertigo is a genuine reflex; that it ought to be ranged side by side with gastric, laryngeal, uterine (*sic*) forms; and that irritation of the branches of the trigeminal supplying the mucous membrane of the walls and septum of the nose is its cause. He thinks that the mechanism is one of cerebral anæmia brought about by the transmission of the irritation through the spheno-palatine ganglion to the vaso-motor nerves. The vertigo is especially induced by slight nasal affections such as result from inhalation of irritating vapours, snuff, &c. Acute coryza, hypertrophic chronic catarrh, mucous polypi, and catarrh of the retro-pharynx are other causes. These reflex effects are most marked in arthritic subjects. The vertigo may be the only symptom, or it may be accompanied by visual troubles, hemicrania, nausea, vomiting, great excitement, hypochondria, intellectual weakness, &c. The statement is also made that the vertigo ceases with the cure of the nasal affection which has caused it.

ELECTRIC LIGHTING ON RAILWAYS.

THERE are certain blunders of omission or commission in policy which appear inexplicable. One of these is the omission to light railway carriages by electricity, and another the recourse to gas and other highly dangerous appliances of illumination. The peril of travelling reservoirs of gas has been painfully illustrated of late. It is strange that any company has had, and still has, the hardihood to subject its passengers to the very grave peril which besets the use of gas in this way. More wonderful still is the neglect to use the motor force available for the self-generation and storing of electricity. Surely there would be no great difficulty in so adapting the necessary apparatus as to make the moving wheels of the carriage do the work of an engine. It is needless to emphasise this suggestion. There is, of course, nothing new in the idea, but it seems to be one of those very obvious matters which are seemingly too plain to be perceived, or in some way fail to impress that particular part of the mental constitution which we call the common-sense instinct. The task of providing trains which travel at night with special accumulators cannot be overwhelming. Those trains that travel by day, and only require lights for tunnels could, we imagine, be utilised to charge the accumulators required by night trains.

DEATH BY ELECTRICITY.

M. D'ARSONVAL has been conducting some experiments for the purpose of preventing fatal accidents from the use of electricity. He has come to the conclusion that electrical currents are not dangerous until a power of 500 volts is reached, and he has devised an ingenious plan by which the extra current which occurs at the moment the current is broken, and which is the chief source of danger, may be annulled or neutralised. A V-shaped tube, made of an insulating material, is filled with mercury and is interposed in the main current. In order to close the main current a tap is turned and the machine is unprimed without giving an extra current spark. Or a glass tube is filled with mercury and dipped into a reservoir containing mercury. This tube is provided with a ground stopper, which not only suppresses the extra current, but interposes any resistance in the current. The invention seems to be original and ingenious, but unless considerable care be taken, even with its assistance, danger is still imminent. Another observation made by D'Arsonval is that extra currents from the dynamic electricity and alternating currents do not produce serious organic disruption of the living tissues like discharges of statical electricity. This, however, is not a new observation. The special disruptive and fatal effect of the statical discharge has long been known in this country, and was most fully brought out in Dr. Richardson's experiments on death by electric shock conducted in the Royal Polytechnic Institution in 1869. In those researches sheep and other animals were killed by the statical discharge, and the cause of death was shown to be due to the sudden expansion of gaseous parts of the blood and tissues, by which organic lesions of the most extensive kind were induced. In one of this series of experiments the skull of a dead animal was fractured by the statical discharge, and arborescent markings of external veins, distortion of large veins, rupture of the heart, ecchymosis, rupture of the stomach, and decomposition of the blood itself, from the same kind of discharge, were phenomena traced to disruption from gaseous expansion. At the same time the statical discharge does not always kill. It may simply stun, or cause a temporary anæsthesia, or produce a state resembling catalepsy, followed by recovery.

COAL MINES REGULATION.

THE recent debate in the House of Commons on the Coal Mines Regulation Bill, if it has not effected any great changes in the system of colliery management at present existing, has not, at any rate, been wholly fruitless of benefit to the employed. The amendment which provides that boys shall no longer be employed underground at an earlier age than twelve years marks a distinct improvement on the former arrangement, which fixed the limit at ten. Health and education will equally gain by the new restriction, and it cannot be urged with any real force that the boys will lose anything in point of technical experience by being kept out of the mines at an age when their mental and bodily powers have hardly begun to develop. The working time (fifty-four hours per week) is still, for such young boys, longer than we could wish, but serious difficulties at present prevent its reduction. As regards girls, who begin their duties at the pit's mouth at the same age as the boys, it has been proposed to fix the earliest limit at fourteen years. Certainly at that age and afterwards they would be fitter for their duties than before it; but as their work is less arduous than that of the boys, and no complaint is made on their account, it would seem that the uniform regulation referred to imposes no hardship upon them. Measures relating to the prevention of accidents were discussed at considerable length, and important suggestions were made respecting the disuse of gunpowder in blasting operations, and the education of miners in the art of "timbering," or supporting the walls and roofs of passages, in order to prevent falls of coal, to which many fatal accidents are due. Technical education is coming to be recognised as one of the crying wants of our time, and the suggestions we have referred to, and the facts upon which they are based, are enough to show that the miner is one of those who stand greatly in need of its advantages.

CONVERSAZIONE AT THE ROYAL COLLEGE OF PHYSICIANS.

ON the 29th ult. a conversazione was held at the Royal College of Physicians, the gathering, representative of every branch of the medical and surgical professions, being a large one. The guests were received by Sir William Jenner, Bart., K.C.B., the president; Dr. Habershon, the vice-president; Sir Dyce Duckworth, the treasurer; Sir Henry Pitman, the registrar; and the censors, Dr. Handfield Jones, Dr. Dickinson, Dr. Bristowe, and Dr. Andrew. The staircases and various apartments were tastefully decorated with flowers and palms, and the band of the Coldstream Guards was in attendance. Some interesting scientific preparations were on exhibition during the evening: notably a collection of bacterial cultivations and microscopic specimens by Mr. Edgar Crookshank; a new form of sphygmograph, invented by Professor Ludwig, by Dr. Lauder Brunton; and a diffraction spectroscope with concave grating of six-feet focus, ruled by Professor Rowland, by Dr. W. H. Stone. There were also a number of paintings and other works of art exhibited.

DRUGS, APOTHECARIES, PHYSICIANS, AND ROYAL PATIENTS.

WHILE ready to recognise that Sir William Gull in his recent deliverance on the independence of physicians and their Royal patients of drugs and apothecaries must not be taken too literally, we cannot forbear giving our readers the following delightful quotation from Mr. John Evelyn, to show how the lives that make history are affected and even saved by suitable medicines, in the introduction of which good apothecaries may have a creditable share:—

"1694.—29th Nov. I visited the Marquiss of Normanby . . . . . and had much discourse concerning the *Quinquina* which the Physicians would not give to the King, at a time when in a dangerous ague it was the only thing that could cure him (out of envy because it had been brought into vogue by Mr. Tudor an apothecary), till Dr. Short, to whom the King sent to know his opinion of it privately, he being reputed a Papist (but who was in truth a very honest good Christian), sent word to the King that it was the only thing which could save his life, and then the King injoined his physicians to give it to him, which they did, and he recover'd. Being asked by this Lord why they would not prescribe it, Dr. Lower said it would spoil their practice, or some such expression, and at last confessed it was a remedy fit only for Kings."

DISCOVERY OF DIAMIDE.

A VERY interesting discovery has just come to us from Germany. The author, Theodor Curtius, investigating diazo-acetate of ethyl, found that by the action of potash a yellow crystalline compound was obtained, which in its turn was changed by sulphuric acid into white crystals, which proved to be the sulphate of the long-sought base diamide N_2H_4. The important compounds called amides and amines contain, as is well known, the radical NH_2, formerly known as amidogen, which is the true analogue of hydroxyl, OH, and cyanogen, CN. This radical has at last been isolated, but, as in the case of the other normal radicals, the formula must

Digitized by Google

be doubled, and the free compound is N_2H_4 or $NH_2.NH_2$. The base is easily obtained from its sulphate by the action of alkalies, and is a very interesting substance, about which we shall soon know more. It is a gas soluble in water and fuming with hydrochloric acid. Its solution is a base, and turns red litmus to blue, and yet it is in smell and in other respects different from ammonia. It is a powerful reducing agent, readily reducing Fehling's solution and nitrate of silver. Its salts are suddenly decomposed by heat, and yield nitrogen when treated with nitrous acid, which last reaction shows their true amidic nature. The further study of this most interesting substance will be awaited eagerly by all chemists.

JUBILEE ADDRESSES TO HER MAJESTY.

AT a Court held at Windsor Castle on the 27th ult., addresses were received by Her Majesty from deputations from the following, amongst other societies and corporations:—Royal College of Physicians of London (Sir William Jenner, President, and Sir Henry Pitman, Registrar); Royal College of Physicians of Edinburgh (Dr. George Balfour, Vice-President, and Mr. R. P. Ritchie, Treasurer); King and Queen's College of Physicians in Ireland (Dr. James Little, President, and Dr. J. W. Moore, Registrar); Royal College of Surgeons of Edinburgh (Dr. Argyll-Robertson, President, Surgeon-Oculist to the Queen in Scotland, and Dr. John Smith, Vice-President); Royal College of Surgeons in Ireland (Dr. Anthony Corley, President, and Mr. Henry Fitz Gibbon, Vice-President); and the British Medical Association (Dr. W. Withers Moore, President, and Sir Walter Foster, M.P., President of the Council). In the above list, it will be observed, the Royal College of Surgeons of England is not included. This may be accounted for by the fact that the address of the College was presented through the usual channel of the Home Secretary, the authorities being unaware that they might have had the same personal presentation to Her Majesty as the other corporations.

PROFESSOR HASSE ON UNIVERSITY REFORM.

IN a recently published paper on Desirable Reforms in German Universities, Professor Hasse of Breslau proposes that all professorial chairs should be vacated as the occupants reach the age of sixty-five; that the salary should, however, continue to be paid with little or no reduction; the ex-professor to be at liberty to give lectures still, but to be deprived of his seat and vote in the Faculty, and to be ineligible for any examinerships. Amongst other reforms desired by the Breslau Professor of Anatomy is a regulation preventing students from taking their Doctor's degrees before they have passed the State examination, as he knows instances in which men with such a *quasi* qualification have engaged in practice.

BOAT OWNERS AND BOATING ACCIDENTS.

A FEW days ago a young man while rowing on the Thames accidentally lost his life by drowning. He was evidently quite unable to row, and the unfortunate occurrence appears to have been directly due to his want of skill in this particular. While proceeding up the river in an outrigged boat against the tide, he suddenly stopped rowing with one hand, and he was thrown into the water. At the coroner's inquest upon this case several of the jury expressed their disapproval of the conduct of boat proprietors in letting out their craft without inquiry to inexperienced persons. We certainly agree with those members of the jury, that it is most unadvisable for anyone ignorant of the management of boats to make an essay in rowing under the conditions which proved so fatally unsuitable in this case, and also that it would be well for boat owners to ascertain, if possible, whether those who hire their boats can be trusted to navigate them. At the same time, the chief responsibility for an accident of this kind must rest with the too venturesome rower, and it would therefore be too much to expect that a proprietor should be bound by law to inquire into the boating qualifications of the public who resort to him. His duty is to provide a good boat, with any special information as to its management which may be called for, but the occupant alone can be held accountable for his temerity in using it when he should not.

THE MIDDLESEX HOSPITAL.

THIS hospital was closed on the 1st inst., and will remain closed for about two months, in order to allow of its being thoroughly repaired and the kitchen and laundry departments reconstructed. Surgical out-patients will, however, continue to be seen by the assistant-surgeons until the 15th inst., whilst the cancer wards and the midwifery department will still remain open. In connexion with the cancer department, it may be noted that a ward has now been entirely set apart for male cancer patients, with a day-room adjacent to it, the cost of such alteration being defrayed by a sum of money placed in the hands of Dr. Greenhow, consulting physician to the hospital, for this purpose. The new buildings in connexion with the hospital and medical school are also progressing actively, the nursing institution being nearly completed, and the new and handsome residential college for students being almost as far advanced. Mr. Leopold Hudson has been appointed warden of the college, which will be quite ready for occupation by the opening of the winter session.

AUSTRIAN HEALTH RESORTS.

The Times of June 22nd began publishing a series of articles "from a correspondent" on Austrian health resorts, which cannot fail to be of much interest to many who are contemplating an autumnal holiday to some continental inland watering-place. The gouty, the rheumatic, the dyspeptic, and the overwrought find in such a change relief and invigoration, which strictly medicinal treatment at home often fails to accomplish. It is not sufficient for such persons that their change should have a directly medical object, and be confined to drinking this or that natural mineral water, though this may form a very important element for the relief of their discomfort. But the air, scenery, elevation above sea level, as well as amusements and novel experiences of life, with facilities of travelling, are matters needing careful preliminary consideration, both by the doctor and the patient. The medical adviser has much difficulty in selecting the kind of place that is likely to be beneficial as well as agreeable to his patient. A large number of persons who go to continental watering-places need the one as much as the other. Numbers of persons can be equally well treated medicinally at any one of three or four places, though in some instances, no doubt, a particular place is best suited to a particular case; and this is a matter which medical opinion can best settle. But in other instances, where the appurtenances of medicinal treatment have to be considered, the patient may fairly have a voice in the selection, and he could scarcely do better than read the articles referred to in order to fit himself to exercise a right judgment in this respect; nor are the articles without their value to medical men. At the same time, it is important for the English public to bear in mind that there are in the British Isles health resorts that afford all the advantages enjoyed by continental spas, without the disadvantages, chiefly of an insanitary kind, which characterise very many of them.

THE VETERINARY PROFESSION.

IN another column we publish a letter from a well-known veterinary surgeon (Mr. James Lambert), who has misinterpreted an annotation we published in our issue of last week on the veterinary and medical professions. Our annotation was written in opposition to certain statements reflecting on veterinarians. We can but refer him to the article itself, and we think that no useful object would be served in discussing the statements that he has made. But we must protest against his conclusion that the medical profession is not desirous of working with the veterinary in the study of disease; the intimate relation which exists between human and animal affections is, apart from other reasons, sufficient ground for a close alliance, and we observe with satisfaction that the Agricultural Department have called to their aid a medical pathologist. We have already expressed our opinion that a skilled veterinarian should be attached to the Medical Department of the Local Government Board, for it is by such co-operation that the best results will be obtained.

MEMORIAL PORTRAIT OF SIR WILLIAM JENNER, BART., K.C.B., M.D.

THE Executive Committee wish it to be known that the list will not remain open much longer. Intending subscribers are therefore requested to send their contributions to one of the treasurers (Dr. Charles J. Hare and G. D. Pollock, Esq.) without delay. A list of the subscribers, but not the sums contributed, will be published.

BOULTER'S LOCK.

SURELY it is time that a more serious attempt was made by the Thames Conservancy to prevent a scene such as that witnessed so often at Boulter's Lock on Sunday evenings. It is a disgrace to the river, as those who have been present can testify. Above the lock are crowded scores of boats, the occupants of which are anxious to get through, possibly in order to catch a train at Maidenhead. There is no order, each tries to get in when the doors are opened, and tries with might and main to get first, whilst those behind hang on those in front and completely stop progress. Steam launches push forward, and the planks of the smaller boats give way; the excited and angry owners shout and use strong language, ladies scream as they hear and see the sides of their boat staved in, and occasionally a man is thrown into the water. The lock-keeper does what he can, but that is little. The confusion is rendered worse by the shouts, jeers, and laughter of the crowd on the banks and sides of the lock. Hours are spent in this almost hopeless struggle, and we fear that before long, unless some remedy is found, there will be loss of life, as well as destruction of property. Are we to wait for the verdict of a coroner's court on some helpless pleasure-seeker before an attempt is made to prevent what must be regarded as little less than a scandal?

WHITECHAPEL DISTRICT.

THE District Board and the Board of Guardians of Whitechapel have memorialised the Metropolitan Board of Works to proceed without delay in dealing with the Bell-lane area, the conditions of which they regarded as a physical and moral danger and a great scandal to the whole metropolis, their spokesman, the Rev. Mr. Billing, stating that they were quite ready to suffer any loss which might be entailed by the removal of the houses and the consequent temporary loss of rates. The memorial was referred to a committee, and it may be hoped that the much-needed improvement will not long be delayed. The cost of the proceedings, which are taken under the Artisans and Labourers' Dwellings Improvement Acts, fall upon a general metropolitan rate, and the well-to-do districts of London bear their burden of the expense. There is a general desire that the present year should be marked by the social advancement of the people, and it is to be hoped that the Metropolitan Board will not hesitate to exercise the large powers that they possess for this purpose.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced: — Dr. Karl Damian Ritter von Schroff, formerly Professor of Pharmacology and Pharmacognosis in Vienna, at the age of eighty-four, at Gratz, the residence of his son Dr. Karl Ritter von Schroff, who is Professor of Materia Medica in that University. The deceased *savant* was the founder of scientific methods of studying and teaching pharmacology in Vienna, where he established the Pharmacological Institute, in which building so many important and valuable researches on drugs and on their action on the animal economy have been carried out by himself and his pupils. He held his professorship for twenty-four years, till, indeed, he was seventy years of age, since which time he had been living in Gratz with his son.— Dr. Joh. Pasternazki, *docent* of Mental Diseases and physician in charge of the department for Mental Diseases in the Ujasdowsches Military Hospital in Warsaw.

HOLYHEAD SANITARY ADMINISTRATION.

THE question asked in Parliament as to the sanitary condition of the Holyhead Rural Sanitary district, and as to the appointments of the officer of health and the inspector of nuisances, indicates that inefficiency on the part of the authority has been discovered, and, in all probability, this inefficiency is most marked in respect to the position which the authority have assigned to their officers. Why the report has not been published we cannot say; but we do know that Mr. Harvey, the reporter, is an expert in sanitary work, that he is a painstaking official, and that any advice he has given is likely to be sound. As regards the medical officer of health, we note, from the published list, that he holds office for Holyhead rural, Holyhead urban, Anglesey rural, and Beaumaris urban districts at a salary which can only have been assigned on the understanding that he was not expected to do much. Perhaps the refusal of the central authority to sanction the appointment of the inspector of nuisances is based on similar considerations of fee. If so, we hope the authority for this widely scattered district will not get their own way by bringing an imaginary grievance before Parliament.

VACATION CLASSES AT VIENNA AND BERLIN.

THE programme of medical courses of instruction at Vienna during the months of August and September has been issued. The number of such classes is now very large, and of their convenience for foreigners there can be no question. Most of them are complete within a month, meetings being held daily. Amongst them may be noted those on morbid anatomy (Dr. Adolf Zemann); pathological histology (Dr. Kolisko); bacteriology (Prof. Weichselbaum and Prof. von Frisch); medical diagnosis (Drs. von Frisch and E. Neusser, Drs. Bamberger and Lorenz, Drs. von Langer and Heitler, and Dr. Drozda); diseases of the organs of circulation (Dr. Bettelheim); diagnosis of brain and spinal cord diseases (Dr. Benedikt); and the pathology and treatment of nervous diseases (Prof. Rosenthal). There are also courses on forensic medicine, urinology, practical and operative surgery, ophthalmology (no fewer than seven different

Digitized by Google

courses), gynæcology, laryngoscopy, otology, dermatology (Prof. Kaposi and Dr. Riehl), syphilis, &c. An even more complete series of post-graduate classes of a like kind will be held in Berlin, from the 26th of September to the end of October, of which the announcement will be found in the *Berliner Kliniker Wochenschrift* for June 27th, p. 483.

A MUNIFICENT GIFT: THE PROVIDENT DISPENSARY MOVEMENT.

AT the annual meeting of the Metropolitan Provident Medical Association, Sir Julian Goldsmid, M.P., presiding, it was reported that no new branches had been opened, but that the old ones had been successfully maintained. About half of the branches are self-supporting. The payments to medical men had amounted in 1886 to £1500, and for drugs to over £400. It is not said amongst how many medical men the £1500 were divided. The sum contributed by the members was £3000; that contributed by the committee to meet deficiencies was £214, or 7 per cent. It has been determined to recommend to local committees to make a charge of 1*d.* for the dispensing of every prescription. Mr. Bousfield announced that a Jewish gentleman, not resident in England, had given to the Association a donation of £3000 towards the establishment of provident dispensaries in memory of his son. We believe that the liberal gentleman in question is Baron Hirsch of Vienna, whose example is worthy of imitation.

THE REPEATED SERVICE IN WESTMINSTER.

WHATEVER criticisms may be made on the general features of the Jubilee celebration—and there is room for some,—it is very gratifying to notice that a sum not far short of £2500 was received from the Wednesday service, and very quickly divided amongst the medical charities of London—a third going to the Hospital Sunday Fund, a third to the Westminster Hospital, and a third to the Western Dispensary and the Hospital Saturday Fund jointly. Dean Bradley, in his letter to *The Times*, thanks all who have co-operated in the "service." We would add our thanks to the Dean himself for his share in such a use of the Abbey as has contributed a splendid contribution to a cause as meritorious as it is needy.

AN HONOUR DECLINED.

IT is indicated in the *Glasgow Herald* that Professor Gairdner has been offered, but has very courteously declined the honour of knighthood. We make no secret of our deep dissatisfaction, extensively shared by the profession, with the dispensation of Jubilee honours. Apart from the reasonable expectations of our own profession, the dispensation is exceedingly disappointing and unworthy of the occasion. We are glad, however, that Professor Gairdner has not been forgotten, for in him there meets all that is best in Scotch medicine.

SCARLET FEVER CONVALESCENTS.

[illegible] annual meeting of Miss Mary Wardell's Convalescent [illegible] those recovering from scarlet fever was held a few [illegible] under the presidency of Sir Risdon Bennett. [illegible] last year 158 patients have made use of the [illegible] children of all classes of the community. [illegible] payment, the terms for ordinary patients, [illegible] a week; for children, 10*s.* The Home is [illegible] on the top of Brockley Hill, near Stan[illegible] real want in cases to which all ordi[illegible] denied. In an age of great prac[illegible] few pieces of work more prac[illegible] Wardell's. There is still a debt on [illegible] is wanted to supply certain [illegible] for domestic purposes.

THE CROWN PRINCE OF GERMANY.

DR. MORELL MACKENZIE removed another portion of the growth in the larynx of His Imperial Highness on Wednesday last, and we are glad to know that he is satisfied with the progress of the case. The portion removed has been forwarded to Professor Virchow for examination.

INTERMEDIATE M.B. EXAMINATION.

THE Medical Faculty of King's College at their last meeting resolved to send a letter to the Senate of the University of London, pointing out the grave inconveniences which have been caused to lecturers engaged in summer courses by changing the date for the commencement of this examination from the fourth to the second Monday in July.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Professor Hertwig of Jena, has been nominated for the second Professorship of Anatomy.

Cracow.—Professor Adamkiewicz has been given the charge of the newly-established Institute for Experimental Pathology.

Naples.—Professor Vincentis, of Palermo, has been appointed Professor of Ophthalmology.

WE have to record the death, in his eighty-sixth year, of the Hon. Grant Ellcock Thomas, M.D., late, and for upwards of twenty years, President of Her Majesty's Council in the Island of Barbadoes, which took place at his residence in Barbadoes on the 10th ult. Not only in the island, where he had long been resident, but throughout the West Indies generally, no one was better known or more universally respected than Dr. Thomas. Upon his retiring from the office of President of the Council some ten years ago, he was offered a knighthood, an honour which, while gratefully appreciating the intention, he respectfully asked to be allowed to forego, mainly owing to his advanced years.

AT a conference of the Glasgow Medical Charities' Committee with the Medical Committee of the Charity Organisation Society on the 23rd ult., it was, after some discussion, resolved to hold a conference with the members of the boards of management of the medical charities of the city and of the parochial boards, for the purpose of discussing any points connected with the abuse of medical charity which may require elucidation, and for appointing a final and representative committee to take the most advisable steps in the way of instituting a definite and practicable system of restricting gratuitous aid to the needy and deserving poor.

HOFRATH DR. HOFFMANN having retired from the post of Director of the General Hospital, Vienna, Professor Böhm has been appointed to this most important office, the said hospital being, we believe, the largest hospital in the world.

THE editorship of the *Fortschritte der Medicin*, vacant by the death of Professor Carl Friedländer, who himself established this important and valuable journal, has been taken over by Professors Carl Weigert and Heinrich Unverricht.

PROFESSOR HUMPHRY has been appointed delegate from the University of Cambridge to attend the International Congress of Hygiene, to be held at Vienna in September.

DR. W. B. HADDEN has been elected assistant-physician to the Hospital for Sick Children, Great Ormond-street.

Digitized by Google

PROFESSOR BILLROTH'S strength has been sufficiently restored to enable him to remove to his country house, St. Gilgen.

DR. JULIUS MICKLE has been nominated to deliver the Gulstonian Lectures at the Royal College of Physicians next year, and Dr. Dickinson the Lumleian Lectures.

ROYAL COLLEGE OF PHYSICIANS.

AN extraordinary Comitia of the Royal College of Physicians was held on June 27th, the President, Sir W. Jenner, Bart., in the chair.

The President announced that the Registrar and himself had attended at Windsor that afternoon by command for the purpose of presenting to Her Majesty the Queen the address of congratulation lately drawn up by the College.

Dr. Robert Saundby was admitted to the Fellowship of the College.

A report was received from the Committee of Delegates on the appropriation of the vacant ground on the Embankment, and after considerable discussion, mainly in reference to the size of the proposed lecture theatre, the report was adopted after amendment by the omission of paragraphs relating to that subject. The gist of the amended report will be found in the abstract of the proceedings of the Royal College of Surgeons, which appears in another column.

The College next proceeded to consider the report of the Committee of Delegates appointed by the two Colleges to consider the desirability and practicability of granting degrees in medicine and surgery to persons who have passed the conjoint examinations of the two Colleges. The subjects dealt with by the committee were:—1. The communication from the Councils of King's College and University College, London, inviting the two Royal Colleges to confer with committees of those Councils in order to combine, if possible, the objects of all four Colleges, and to make a united application to the Crown for power to grant degrees in arts, science, and medicine. 2. The mode in which application should be made to the Crown by the Royal College of Physicians of London and the Royal College of Surgeons of England for power to confer degrees in medicine and surgery. With respect to the first subject, the committee recommended, and the resolution was adopted by the College by a large majority, "That it is desirable that the two Colleges proceed, conjointly and independently of other bodies, with their endeavour to obtain the right to confer degrees in medicine and surgery, and that therefore it is at present inexpedient to hold a conference with the University and King's Colleges for the purpose of procuring further powers to grant degrees in arts and sciences." The second question embraced the text of a draft petition to the Crown for a Charter and power to grant degrees, and also a draft Charter constituting twenty-four Fellows of the College of Physicians, together with twenty-four members of Council of the College of Surgeons, a corporate body, to be entitled the Senate of Physicians and Surgeons, which "shall have power to confer on any person who, by passing the examinations formerly held by both of the said two Colleges separately, or by passing the examination held by the examining board of the said two Colleges, or by passing any other examinations to be held by the two Colleges jointly or separately, has already acquired, or may hereafter acquire, the qualifications for registration under the Medical Act, and who shall have also complied with any further regulations (if any) or undergone such further examination (if any) as the Senate may from time to time see fit to impose or require as a qualification for a degree, both or such one as the Senate may think proper of the following degrees—namely, the degree of Bachelor of Medicine and Bachelor in Surgery, and the degree of Doctor of Medicine." This portion of the report was also adopted, and referred back to the delegates to carry into effect.

A report was received from the Leprosy Committee in the form of a reply to a memorandum from the Colonial Office, in which the opinion of the College of Physicians was sought as to the contagiousness of leprosy and the advisability of segregating lepers. The report advised the formation of proper leper asylums for humane treatment of the victims of this disease, and considered this a proper matter for State interference; but as no definite opinion was expressed in the report upon the question whether the College adhered to the statement of its committee of 1867, to the effect that the disease was not contagious, it was, after much discussion, referred back to the committee, with an instruction to embody in it a suggestion to Government to undertake anew the investigation of the disease, in order, if possible, to determine this question.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an extraordinary meeting of the Council of the Royal College of Surgeons held on Monday, June 27th, the Minutes of the Ordinary Council of the 9th inst. were read and confirmed.

A letter was read from the Secretary of State for the Home Department reporting the presentation to the Queen of the address of congratulation from the Council to Her Majesty on the completion of the fiftieth year of her reign.

The third report of the Committee on the Extension of the College Premises, which was approved and adopted at the previous meeting, was confirmed. It contained the following recommendations:—1. That the library be enlarged by pulling down the house No. 39, Lincoln's-inn-fields, at present occupied as a residence by the conservator, and that the space thus gained be added to the library, in the manner suggested by the architect, at an approximate cost of £2500. 2. That the house No. 38, Lincoln's-inn-fields, now occupied as chambers on annual tenancies, which is in a most unsatisfactory condition, be also pulled down and be converted into a residence for the conservator. 3. That a pathological curator, the whole of whose time shall be at the disposal of the College, and who shall not be in practice, be appointed, at a salary of £500 a year; and that such assistance, involving a probable additional expenditure of £300 per annum, be employed in the pathological department of the Museum, as the Museum Committee may from time to time recommend to the Council.

A fourth report from the same committee was approved, adopted, and entered on the Minutes. In this report it was decided to advertise the office of pathological curator, with a view to filling up the post in November; the Museum Committee to frame the rules governing the duties of the office.

Mr. W. Morrant Baker was elected a member of the Court of Examiners in Surgery to fill the vacancy caused by the resignation of Mr. Lund.

On the motion of Mr. Heath, seconded by Mr. T. Smith, and carried, it was agreed that, for the present, this Council do not spend more than £50,000 of the Erasmus Wilson bequest.

The report of the Colleges' Land Committee, consisting of delegates of the two Colleges, on the question as to the desirability of utilising the vacant ground adjoining the Examination Hall for "scientific purposes," under the control and management of the two Colleges, and that the "scientific purposes" be in the first place the investigation and exposition of such branches of science connected with medicine and surgery as the two Colleges may from time to time determine, was approved, adopted and entered on the Minutes. It was briefly as follows:—1. That a central theatre for lectures and demonstrations should constitute a part of the proposed additional buildings. 2. That the central theatre should be built so as to contain seats for an audience of about 250 persons. 3. That the plan submitted by the architect be, in its general arrangements, adopted, it being understood that the theatre shall be constructed to contain about 350 persons, and that the side wings be proportionally enlarged. 4. That a subcommittee be appointed to investigate and report upon the best arrangements at present existing in scientific institutions in the construction of a lecture theatre and laboratories. 5. That the appointment of the subcommittee be left in the hands of the two presidents of the Colleges, and that the subcommittee be requested to report within four months of this date to the committee.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

Copy Draft Petition for Charter and Power to grant Degrees.

TO THE QUEEN'S MOST EXCELLENT MAJESTY IN COUNCIL.

THE humble petition of the Royal College of Physicians of London and of the Royal College of Surgeons of England humbly sheweth as follows:—

1. Your petitioners, the Royal College of Physicians of London, are a corporation who, under an Act of Parliament, made and passed in the fourteenth and fifteenth years of the reign of his Majesty King Henry the Eighth, intituled the Privileges and Authorities of Physicians in London, and confirming certain letters patent, bearing date at Westminster, the 23rd day of September, in the tenth year of the reign of his said Majesty, were incorporated, established, and empowered by their then name of the President and College, or Commonalty of the Faculty of Physic in London, but are now known by the name of the Royal College of Physicians of London, and pursuant to bye-laws of the Corporation are governed by the president and Fellows of the College.

2. Your petitioners, the Royal College of Surgeons of England, are a Corporation incorporated or re-established and empowered under letters patent, bearing date at Westminster the 22nd day of March in the fortieth year of the reign of King George the Third; and further empowered by letters patent bearing date at Westminster the 13th day of February, in the third year of the reign of King George the Fourth, and by letters patent bearing date at Westminster the 14th day of September, in the seventh year of your Majesty's reign, whereby their present name was conferred on the corporation; and also, by further letters patent bearing date at Westminster the 18th day of March, in the fifteenth year of your Majesty's reign, and your petitioners, the Royal College of Surgeons of England, are now in accordance with the provisions of the said several letters patent, and their bye-laws and ordinances governed by a Council consisting of twenty-four persons elected by the Fellows of the corporation, and one of such twenty-four persons is the president of the Council and also president of the College.

3. By the Medical Act made and passed in the session of the twenty-first and twenty-second years of your Majesty's reign it was, among other things, enacted that any two or more of the Colleges or bodies mentioned in Schedule A to the said Act (which schedule mentioned along with others your petitioners the Royal College of Physicians of London and also your petitioners the Royal College of Surgeons of England) might with the sanction and under the directions of the General Medical Council, constituted by the said Act, unite and co-operate in conducting the examinations required for qualifications to be registered under the said Act.

4. Your petitioners under the provisions of the Medical Act have accordingly united and co-operated in a scheme constituting an Examining Board of the two Colleges in England and in making regulations for conducting the examinations required for the purpose of qualifications to be registered under the said Act, which scheme and regulations were approved and adopted by your petitioners the Royal College of Physicians of London on the 12th day of March, 1883, and by your petitioners the Royal College of Surgeons of England on the 29th day of April, 1883, and your petitioners have at their own expense caused to be erected and completed on or near the Thames Embankment, in the county of Middlesex, an Examination Hall for the purpose of conducting examinations, and examinations are now duly conducted there under the said scheme and regulations.

5. Your petitioners are desirous, and it is expedient in order to encourage proficiency in the Sciences of Medicine and Surgery, that your petitioners should be enabled to unite and co-operate not only in conducting examinations for the purposes of the Medical Act, but also for the purpose of conferring degrees in Medicine and Surgery on persons who, by passing the examinations formerly held by both of the said two Colleges separately, or by passing the examination held by the Examining Board of the two Colleges, or by passing any other examinations to be held by the two Colleges jointly or separately, have already acquired, or may hereafter acquire, the qualifications for registration under the Medical Act, and who shall have also complied with such further regulations (if any) or undergone such further examinations (if any) as it may be deemed proper to impose or require from time to time, and that for this purpose a Senate of Physicians and Surgeons should be constituted and incorporated, composed of an equal number of Fellows of each of the said two Colleges, with all such necessary or proper powers as your Majesty may graciously see fit to grant or confer.

Your petitioners therefore humbly pray as follows:—That your Majesty will be graciously pleased to incorporate the president for the time being of the Royal College of Physicians of London and twenty-three other persons to be elected from among the Fellows for the time being of the said College and also the president for the time being of the Royal College of Surgeons of England and all the other twenty-three members for the time being of the Council of the Royal College of Surgeons of England being Fellows thereof under the name and style of the Senate of Physicians and Surgeons, with perpetual succession and a common seal and power, by that name to sue and be sued, and with power to grant to persons who have obtained qualifications under the Medical Act and shall be otherwise properly qualified degrees in Medicine and Surgery, and with power, notwithstanding the statutes of mortmain, to take, purchase, and hold to them and their successors lands, buildings, and hereditaments, and with such further powers and subject to such provisions as your Majesty may think proper to grant or impose. And your petitioners will ever pray, &c.

Draft Charter.

Victoria, by the grace of God of the United Kingdom of Great Britain and Ireland Queen, Defender of the Faith, to all to whom these presents shall come, greeting. Whereas the Royal College of Physicians of London are a corporation incorporated, established, and empowered under an Act of Parliament made and passed in the fourteenth and fifteenth years of the reign of his Majesty King Henry the Eighth, intituled the Privileges and Authorities of Physicians in London, and confirming certain letters patent bearing date at Westminster the 23rd day of September in the tenth year of the reign of his said Majesty, whereby certain physicians therein named, and all other men of the same faculty within the City of London and seven miles about, were incorporated and made one body and perpetual commonalty or fellowship of the faculty of physic by the then name of the President and College or Commonalty of the Faculty of Physic in London, but are now known by the name of the Royal College of Physicians of London, and, pursuant to the bye-laws regulating the corporation, are governed by the president and Fellows of the College. And whereas the Royal College of Surgeons of England are a corporation incorporated, or re-established and empowered, under letters patent bearing date at Westminster the 22nd day of March in the fortieth year of the reign of King George the Third, and further empowered by letters patent bearing date at Westminster the 13th day of February in the third year of the reign of King George the Fourth, and by our letters patent bearing date at Westminster the 14th day of September in the seventh year of our reign, whereby their present name was conferred on the corporation, and also by our further letters patent bearing date at Westminster the 18th day of March in the fifteenth year of our reign. And whereas the corporation of the Royal College of Surgeons of England are now, pursuant to the provisions of the said several letters patent and their bye-laws and ordinances, governed by a council consisting of twenty-four persons elected by the Fellows of the corporation, and one of such twenty-four persons is the president of the Council and also president of the College. And whereas by the Medical Act made and passed in the session of the twenty-first and twenty-second years of our reign it was, among other things, enacted that any two or more of the Colleges or bodies mentioned in Schedule A to the said Act (which schedule mentioned along with others the Royal College of Physicians of London and the Royal College of Surgeons of England) might, with the sanction and under the direction of the General Medical Council constituted by the said Act, unite and co-operate in conducting the examinations required for qualifications to be registered under the said Act. And whereas the Royal College of Physicians of London and the Royal College of Surgeons of England have, with the sanction of the General Medical Council, under the provisions of the Medical Act united and co-operated in a scheme constituting an examining board of the two Colleges in England, and in making regulations for conducting the examinations required for the purpose of qualifications to be registered under the said Act, which scheme and regulations were approved and adopted by the Royal College of Physicians of London on the 12th day of March, 1883, and by the Royal College of Surgeons of England on the 29th day of April, 1883, and the said Colleges have at their own expense erected and completed, on or near the Thames Embankment, in the county of Middlesex, an Examination Hall for the purpose of conducting examinations, and examinations are now duly conducted there under the said scheme and regulations. And whereas it is expedient in order to encourage proficiency in the sciences of Medicine and Surgery that the Royal College of Physicians of London and the Royal College of Surgeons of England should be enabled to unite and co-operate, not only in conducting examinations for the purposes of the Medical Act, but also for the purpose of conferring degrees in Medicine and Surgery on persons who by passing the examinations formerly held by both of the said two Colleges separately, or by passing the examination held by the examining board of the said two Colleges, or by passing any other examination to be held by the two Colleges jointly or separately, have already acquired, or may hereafter acquire, the qualifications for registration under the Medical Act, and who shall have also complied with such further regulations (if any), or undergone such further examination (if any) as it may be deemed proper to impose or require from time to time, and that for this purpose a Senate of Physicians and Surgeons should be constituted and incorporated, composed of an equal number of Fellows of each of the said two Colleges, with all such powers as are hereinafter conferred on such Senate. Now, know ye that we of our special grace, certain knowledge, and mere motion at the humble petition of the Royal College of Physicians of London and the Royal College of Surgeons of England do by these presents for us, our heirs, and successors, will, ordain, constitute, grant, and declare in manner following—that is to say:—

1. The following persons—namely, first the president for the time being of the Royal College of Physicians of London, and twenty-three other persons, being Fellows of that College, to be elected for the purpose in the same manner as the Fellows of that College are elected under the bye-laws and regulations of the said College for the time being in force; and secondly, the president for the time being of the Royal College of Surgeons of England, and all the other twenty-three members for the time being of the Council of the Royal College of Surgeons of England being Fellows of that College shall become, and from henceforth for ever hereafter shall be and remain by virtue of these presents one body, politic and corporate by the name of the Senate of Physicians and Surgeons, hereinafter in these our letters patent called the Senate, and by the name of the Senate of Physicians and Surgeons shall and may have perpetual succession and a common seal, with power to break, alter, and make anew the said seal from time to time at their will and pleasure, and by the same name shall and may implead and be impleaded before all manner of justices in all courts and in all manner of actions and suits, and shall be at all times for ever hereafter persons able and capable in law to take, purchase, possess, hold, and enjoy, and shall and may take, purchase, possess, hold, and enjoy, a Senate House and an Examination Hall, with their appurtenances, situate in the county of Middlesex, for the use and purposes of the Senate, and also any other lands, tenements, rents, or hereditaments, wheresoever situate, lying, and being, not exceeding the yearly value of £500 at the time of acquiring the same without incurring any of the penalties in any statute of mortmain, or anything in any statute of mortmain to the contrary notwithstanding.

2. Of the twenty-three persons first elected from the Fellows of the Royal College of Physicians of London to be members of the Senate three persons, to be determined among themselves by the Royal College of Physicians of London, shall go out of office on the first Thursday in July, 1888, and on the first Thursday in July in each following year until all have gone out of office, and when all the twenty-three members first elected have gone out of office, then the three members longest in office shall go out of office on the first Thursday in July in each year, and as between any two or more members who have been in office for the same period the Royal College of Physicians of London shall determine which of them shall go out of office.

3. Any member of the Senate being a Fellow of the Royal College of Physicians of London and going or about to go out of office shall be capable of re-election, and any member of the Senate being such Fellow may

Digitized by Google

resign his office of member of the Senate by letter addressed to the president of the Senate, and upon the going out of office, resignation, or death of any Fellow, or any other vacancy in the number of Fellows of the Royal College of Physicians of London holding such office, including a vacancy caused by succession to office of president of that College, some other Fellow of that College shall be elected in his place by the Fellows of that College.

4. The president for the time being of the Royal College of Physicians of London shall be the first president of the Senate, and shall hold office for such period not exceeding two years, as the Senate shall at their first or any subsequent meeting determine, and on the first president going out of office, the next president of the Senate shall be the president for the time being of the Royal College of Surgeons of England, who shall hold office for such period not exceeding two years, as the Senate at their then next or any subsequent meeting determine, and afterwards the president for the time being of each College alternately shall be president of the Senate for such period not exceeding in each case two years, as the Senate at their next meeting after the succession of a president to office, or at any subsequent meeting, may determine.

5. The Senate may elect any persons not exceeding two of their number to be vice-presidents of the Senate.

6. The vice-presidents shall continue in office for one year from the first Thursday in July in each year, or for such period less than a year, or from such other date as the Senate may from time to time determine, and shall be capable of re-election.

7. The president may resign his office by writing under his hand addressed to the Senate, and any vice-president may resign his office by writing under his hand addressed to the president, and any such writing may be delivered to the secretary of the Senate or any member of the Senate.

8. At any meeting of the Senate the president, if in attendance and if not then one of the vice-presidents who is in attendance, shall take the chair, and in the absence of the president and both the vice-presidents, some other member to be chosen from the members present shall take the chair and act as president.

9. The Senate shall hold their first meeting within six calendar months from the date of these our letters patent in such place and at such time as shall be appointed by writing under the hands of the president for the time being of the Royal College of Physicians of London and the president for the time being of the Royal College of Surgeons of England.

10. The Senate may make such rules and regulations as to the times and places of subsequent meetings and the mode of summoning the same as to the Senate may seem proper, which rules and regulations shall remain in force until altered at a subsequent meeting, and in the absence of any rule or regulation as to summoning a meeting the president for the time being of the Royal College of Physicians of London and the president for the time being of the Royal College of Surgeons of England may by writing under their hands, addressed to each other member of the Senate, summon a meeting at such time and place as they think proper.

11. All acts of the Senate shall be decided by the votes of the majority of members present at a meeting of the Senate, and the chairman shall, in addition to his vote as member of the Senate, have a casting vote in case of equality of votes.

12. No business shall be transacted at any meeting of the Senate unless there are at least twelve members of the Senate present at such meeting.

13. Notwithstanding any vacancy in the number of the members of the Senate, the Senate may exercise all powers conferred on them by these our letters patent.

14. The Senate may appoint a treasurer and secretary, and such other officers (if any) as they think necessary.

15. The Senate shall have power to confer on any person who, by passing the examinations formerly held by both of the said two Colleges separately, or by passing the examination held by the examining board of the said two Colleges, or by passing any other examinations to be held by the two Colleges jointly or separately, has already acquired or may hereafter acquire the qualifications for registration under the Medical Act, and who shall have also complied with such further regulations (if any) or undergone such further examination (if any) as the Senate may from time to time see fit to impose or require as a qualification for a degree, both or such one as the Senate may think proper of the following degrees—namely, the degree of Bachelor of Medicine and Bachelor in Surgery, and the degree of Doctor of Medicine.

16. The Senate may demand and take from each person who offers himself for examination the following fees—namely, for the examination (if any) required for the degree of Bachelor of Medicine and Bachelor of Surgery a fee not exceeding ten guineas, and for the examination (if any) required for the degree of Doctor of Medicine a fee not exceeding five guineas, but shall not demand or take any fee for granting any degree.

17. The Senate may, from time to time, make and alter any bye-laws and regulations (so as the same be not repugnant to the laws of our realm, or to the terms and general objects of these our letters patent) touching the qualifications for degrees, and the granting of the same and any other matters to be done under the provisions of these our letters patent, and all such bye-laws when reduced to writing and under the common seal of the Senate, and approved of and countersigned by one of our principal Secretaries of State, shall be binding on candidates for degrees, and for all other purposes within the provisions of these our letters patent.

18. Provided that any bye-law or ordinance to be made by the Senate shall not be of any force until our approval thereof shall have been signified to the Senate under the hand of one of our principal Secretaries of State, or the same shall have been otherwise approved in such manner as shall be directed by us with the advice and consent of the Lords Spiritual and Temporal and Commons of our realm in Parliament assembled. And we do hereby for us, our heirs, and successors further grant unto the Senate that these our letters patent, or the enrolment or exemplification thereof, shall be in and by all things good, firm, valid, sufficient, and effectual in law according to the true intent and meaning thereof, and shall be construed in the most favourable and beneficial sense for the Senate, notwithstanding any non-recital, misrecital, or imperfect recital, or any other omission, imperfection, or defect whatsoever, in these our letters patent. In witness whereof, we have caused these our letters to be made patent.

Witness ourself at our Palace at Westminster this day of in the fiftieth year of our reign.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Northampton Urban District.—The corrected death-rate for this borough during 1886 was 17 per 1000 living; the infantile death-rate exhibited some decrease, being 155·1 under one year of age to each 1000 registered births. Scarlet fever was more than usually prevalent, having caused 24 deaths; but though efforts are made, by way of disinfection, prohibitions as to school attendance, and visits of supervision, to control the disease, yet nothing seems to be done in respect of hospital isolation. Indeed, the borough infectious hospital has been so contrived as to be largely deterrent instead of attractive to those who should resort to it in the interests of the health of the community. Typhoid fever mortality has fortunately fallen very low in Northampton; only 3 deaths were caused by that disease in 1886. Excellent sanitary work in connexion with infectious diseases, overcrowding, slaughterhouses, &c., was carried out during the year; but amongst the unremedied nuisances, there still remain 127 cases of filthy houses and 62 of faulty drainage. There are parts of Northampton where the housing of the poor must be a constant cause of anxiety, and it is evident that Mr. Cogan does not ignore the needs of the borough in this respect.

Ilkley Urban District.—The annual death-rate for 1886 was 13·4 per 1000 in this northern summer resort, and Dr. Scott states that such infectious disease as prevails is generally the result of importation, the infection being brought in by those who seek a change of air after illness. But the need for means of isolation is none the less recognised, and steps are being taken to procure a hospital. The site provisionally selected is not thought to be the best available, but it must be remembered that perfect sites are not often procurable, and unless there are serious medical or social objections the authority should not be too particular. The need for an extension of drainage is urged, and it is clear that Ilkley stands in want of this further provision. So, also, improvement is called for in the matter of refuse disposal.

Ealing Urban District.—The death-rate in this western suburb only reached 11·3 per 1000 last year, and no death occurred from either scarlatina, small-pox, or diphtheria. Diarrhœa was somewhat fatal amongst children, but not exceptionally so when compared with ordinary urban populations. The new isolation hospital came into use for the reception of seven patients, and public baths have been opened. Amongst the other sanitary improvements which have been provided, Mr. Patten speaks satisfactorily of the destructor, which is used for refuse and for the purpose of dealing with the sludge from the sewage tanks.

Swinton Urban District.—Mr. W. M. Jones, referring especially to measles, reminds his authority that with their open yards, with only one closet to every three houses, with the proverbial sociability of the labouring classes, and with no infectious hospital, he fails to see how, when infection is introduced, it can be prevented from spreading. He trusts that the Swinton, Mexborough, and Wath Local Boards will combine in providing the latter requirement. The privy system which obtains is faulty both in point of its method of construction and in quantity. Dryness of contents, secured by the exclusion of rainfall, slops, and surface soakage, together with systematic mingling of ashes and excreta, can alone justify the midden-privy system, and even then the capacity of the structures must be so limited as to ensure frequent removal of contents by the authority themselves. The death-rate for 1886 was 15·8 per 1000.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 4996 births and 3115 deaths were registered during the week ending June 25th. The annual rate of mortality in these towns,

Digitized by Google

which had steadily declined in the preceding four weeks from 20·4 to 18·4, further fell last week to 17·6, and was lower than in any previous week since the end of June, 1886. During the twelve weeks ending with Saturday last the death-rate in these towns averaged 19·9 per 1000, and was 1·5 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 7·2 in Halifax, 10·5 in Derby, 13·0 in Hull, and 13·3 in Nottingham. The rates in the other towns ranged upwards to 26·7 in Huddersfield, 26·8 in Manchester, 28·4 in Oldham, and 30·1 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 489 and 501 in the preceding two weeks, further rose last week (mainly owing to the increased mortality from diarrhœa) to 512; they included 213 from measles, 127 from whooping-cough, 69 from diarrhœa, 43 from scarlet fever, 31 from diphtheria, 29 from "fever" (principally enteric), and not one from small-pox. No death from any of these zymotic diseases was registered during the week in Plymouth; while they caused the greatest mortality in Salford, Manchester, and Newcastle-upon-Tyne. The highest death-rates from measles occurred in Norwich, Huddersfield, Brighton, Manchester, Salford, Birkenhead, Oldham, and Newcastle-upon-Tyne; from whooping-cough in London, Birmingham, Preston, Cardiff, and Liverpool; and from scarlet fever in Newcastle-upon-Tyne and Blackburn. The 31 deaths from diphtheria in the twenty-eight towns included 19 in London 3 in Birmingham, 3 in Newcastle-upon-Tyne, and 2 in Liverpool. Small-pox caused no death either in Greater London or in any of the twenty-seven large provincial towns. Only three cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease, no new case having been admitted to these hospitals during the week. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding four weeks from 333 to 213, further fell last week to 184, and were 36 below the corrected weekly average. The causes of 74, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Portsmouth, Brighton, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Sheffield, and Bristol.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·9 and 19·3 per 1000 in the preceding two weeks, rose again to 20·3 in the week ending June 25th; this rate exceeded by 2·7 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 14·6 in Perth and 15·8 in Leith, to 21·9 in Greenock and 34·2 in Paisley. The 507 deaths in the eight towns last week showed an increase of 24 upon the number in the previous week, and included 38 which were referred to whooping-cough, 20 to diarrhœa, 9 to measles, 8 to scarlet fever, 5 to diphtheria, 1 to "fever" (typhus, enteric, or simple), and none to small-pox; in all, 71 deaths resulted from these principal zymotic diseases, against 76 and 90 in the preceding two weeks. These 71 deaths were equal to an annual rate of 2·76 per 1000, which was 0·1 below the mean rate from these diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 32, 35, and 38 in the preceding three weeks, declined again last week to 38, and included 14 in Glasgow, 10 in Edinburgh, 8 in Paisley, and 3 in Greenock. The 10 deaths attributed to diarrhœa, of which 4 occurred in Edinburgh and 2 in Glasgow, corresponded with the number in the previous week. Those referred to measles were 1 below the number in the corresponding week of last year. The 9 deaths from measles were 4 below the number in the previous week, and included 5 in Glasgow, 2 in Paisley, and 2 in Greenock. Of the 8 fatal cases of scarlet fever, a decline of 2 from the number in the previous week was returned in Glasgow and 2 in Dundee. Three of the deaths from diphtheria were also returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 109 and 104 in the two weeks, further declined last week to 74, being 14 below the number returned in the corresponding week of last year. The causes of 64, or 12·6 per cent., of the deaths registered in the eight towns were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 31·2 and 26·7 per 1000 in the preceding two weeks, rose again to 27·6 in the week ending June 25th. During the twelve weeks ending on Saturday last the death-rate in the city averaged 28·7 per 1000, the mean rate during the same period being but 18·1 in London and 19·6 in Edinburgh. The 187 deaths in Dublin last week showed an increase of 6 upon the number returned in the previous week; they included 21 which were referred to measles, 4 to scarlet fever, 1 to diphtheria, 1 to whooping-cough, 1 to diarrhœa, and not one either to small-pox or "fever." Thus the deaths resulting from these principal zymotic diseases, which had been 21, 29, and 32 in the preceding three weeks, declined again last week to 28; they were equal to an annual rate of 4·1 per 1000, the rates from the same diseases being 3·1 in London and 3·0 in Edinburgh. The fatal cases of measles, which had increased in the preceding seven weeks from 6 to 18, further rose last week to 21. The deaths from scarlet fever, on the other hand, were fewer by 2 than the number in the previous week. The deaths of infants showed a considerable further increase upon recent weekly numbers, and those of elderly persons were also rather more numerous. Six inquest cases and 8 deaths from violence were registered; and 41, or nearly a quarter, of the deaths occurred in public institutions. The causes of 29, or more than 15 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

HAY ASTHMA.

To the Editors of THE LANCET.

SIRS,—As a severe sufferer for some forty-five years, perhaps a few personal experiences, as recalled by Sir A. Clark's lecture in your issue of the 11th inst., may not be unacceptable. My earliest recollections go back to school-boy days (aged eleven or twelve) of severe convulsive sneezing fits, some twenty-five or thirty acts in quick succession, in the summer months, and frequently in school hours, insomuch that I was suspected of causing them artificially and mischievously. Thence up to the age of fifty-six I suffered every summer. The attack commenced in May as slight catarrh, discharge and itchiness in nostrils and at inner canthi, sudden paroxysmal fits of sneezing, increasing in severity and frequency, some fifteen or twenty attacks daily, itchiness of nose and eyes becoming constant and almost unendurable, catarrhal conjunctivitis, hoarseness and sore throat supervening. The seizures mostly came on without warning and spontaneously, but a slight cause, a glare of sunshine or sudden breath of air, often evoked them. The alæ nasi, sore and chapped from friction, were intensely sensitive. The paroxysms were often cut short by an unusually violent convulsive effort to sneeze unexpectedly aborting. Hay or grass field invariably brought on an attack, otherwise climate or locality made little difference, except that during long sea voyages (round the Cape) I was free. My most painful reminiscences are of Manchester and Simla, than which no two climates can be more antithetic. At Mean Meer and Kurrache desert stations,

> "Where the bird dare not build, or insect wing
> Flit o'er the HERBLESS granite,"

I was as bad as at home.

The sequel is curious. At about fifty-six I became suddenly free, and have so continued, but with total absolute loss of all sense of smell, and consequent serious impairment of taste. As to heredity: for three generations, on both sides, I am the sole sufferer; but since last summer, the youngest of seven children, a lad of eighteen, has been seized. As to "nervous constitution:" in these instances I think it must be ignored. My own life has been active, more in the camp than in the study. My son is captain of his school's boating and football clubs. Though I consider myself free, yet perhaps I sneeze oftener than most people. A short time ago a gentleman asked me if I noticed anything particular in the room we were sitting in (a public reading room), as he himself never entered it without being attacked. There is a physiological puzzle in

Digitized by Google

the fact that snuff, however pungent, will not affect the taker if his attention is taken up, and, as it were, kept moving by confederates.

Perhaps connected with loss of smell I may add there comes now and then a subjective unearthly, not unpleasant sense, passing into vertigo and momentary unconsciousness. I underwent various methods of treatment without any alleviation. I remain, Sirs, your obedient servant,

H. D. F.

THE PURITY OF DRUGS.

To the Editors of THE LANCET.

SIRS,—In the article on adulteration which appeared in your issue of June 18th, you say, in reference to the purity of drugs: "The manufacturer commands the situation, for the dispenser cannot analyse every drug which he dispenses." As one who has had some twenty years' experience in pharmacy, I beg to differ from you; and as I am now not in business, I hope I take an unbiased view. I consider the dispenser who cannot guarantee the purity of every drug which he dispenses, either because he has made it or because he cannot analyse it, is not worthy of the confidence of the medical man whose instructions he has to carry out or of the patient whose money he takes. There are, I maintain, many pharmacists, some of whom are only in a small way of business, who are prepared to guarantee personally every drug which they dispense. If they cannot do so they have no right to demand special remuneration. The "examinations of the Pharmaceutical Society" are intended to test a man's qualification for this duty, and the spirit of emulation and the encouragement he receives from the members of the medical profession prompt him to its performance. Manufacturers, I am sure, would not agree with you in thinking they command the situation. They are animated by the same spirit as their brethren in the retail, and will do all they can to advance pharmacy, but they do not and cannot relieve the pharmacist of his personal responsibility. A drug or chemical which is not what it is represented to be, but which has by some mischance come into the market, does not, as a rule, have a very long run; some careful pharmacist detects its deficiency, due notice appears in the *Pharmaceutical Journal*, and usually it is immediately withdrawn. As an example, I may mention the notice of "Drumine" in that journal of June 18th. The real nature of this so-called alkaloid was detected by Mr. A. E. Tanner, and physicians were saved a long physiological trial of a worthless article. In such cases as the above, I agree with you that prosecution is not needed, a warning is sufficient. In any case of wilful adulteration, by all means punish the delinquent with the utmost rigour of the law, but as a rule it is by some oversight that drugs are below par. No class of the community so much desire the purity of drugs as pharmacists, and they would hail with gladness any means likely to improve the present high standard of purity. The members of the medical profession have it in their power to do more to advance this high standard for drugs than any amount of legislation. Let them entrust the dispensing of their prescriptions to those pharmacists who are prepared to give a personal guarantee with every drug which they dispense, and they will find that the dispenser can analyse every drug which he dispenses.—I remain, Sirs, your truly,

Fellowes-road, N.W. W. H. SYMONS.

A THERAPEUTICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—Several medical men in London and the provinces have determined to endeavour to form a "therapeutical society" in order to combat the present chaotic condition of the science. It is proposed that this society should not be representative of any particular school or theory of medicine, but be open to all qualified members of our profession. This proposition may appear somewhat startling to the older members of medical bodies, but it is considered that the "old order changeth, yielding place to new," and that the lines between so-called orthodox and unorthodox medicine have greatly changed their bearings. It will not be disputed by any of your readers that all members of our profession are actuated by one wish—viz., to cure or at least to diminish the sufferings of those who place themselves under their care. The various medical annuals that are published show what changes have taken place in treatment within the past few years, and the labours of Professors Ringer and Brunton have revolutionised the practice of medicine. It is further proposed that a "quarterly journal of therapeutics" should be published, edited by one or more well-known writers in this science. I have already obtained several names of medical men who are willing to assist in the formation of the society, and hope to be able to collect a sufficient number to call a meeting in October in order to arrange final details, to appoint officers, and to settle terms of subscription. If any of your readers would aid me in this matter by suggestions, or by sending in their names as willing to join the society when formed, they would greatly oblige. I am Sirs, yours faithfully,

A. GEORGE BATEMAN,

64, Longridge-road, S.W. Acting Hon. Sec.

THE VETERINARY PROFESSION AND PUBLIC HEALTH.

To the Editors of THE LANCET.

SIRS,—In an annotation in last Saturday's LANCET a lecture is given to the veterinary profession, and it is more than hinted that many of its members are inclined to look slightingly on scientific investigation, and at its conclusion a hope is expressed that the contagious diseases of animals may soon be as well differentiated as those of mankind are by the medical profession. May I be allowed, as a veterinary surgeon, to criticise our critics, and make a few remarks on the sometimes injudicious attitude of the medical towards the veterinary profession?

Let me begin by saying that we claim to be as scientific as the medical profession, and in proportion to our number to possess at least as many devotees of research. So far from being averse to scientific investigation, we gladly welcome it; but we should not be blamed because we do not at once accept the somewhat startling conclusions of Dr. Klein. We do not deride them, we wait for confirmation; and, with every disposition to assist his inquiries, we reserve our judgment.

As to the differentiation of the contagious maladies of animals, we claim to have made at least as much progress in that respect as has been made by the medical profession in human diseases; and we do not, as some of the medical profession do, every now and then make gratuitous attacks on what should be a sister profession in the daily press—attacks which (forgive me for saying so) almost invariably turn out to be ridiculously unfounded, and based on defective knowledge and information. I could give you numerous and laughable examples in this regard, dating from the time of the great cattle plague of 1865, and coming down to the present day.

If we may be, for once, quite good-humouredly, recriminative, we might point to what I will venture to call the very numerous *opprobria medicorum*, among which may be named phthisis, syphilis, cancer, pneumonia, diphtheria, rheumatism, tetanus, and a host of other maladies, of which the nature is not yet understood, and for which the treatment of the best medical authorities is so varied and contradictory as to show the thinking observer that the healing science is yet only on the threshold of knowledge, and that it has still far more to learn than it has thus far learnt since it first began to be rationally studied. Of course, I do not deny that in mine, as in all professions, some of the "old school" affect to look down upon scientific knowledge, but it is the same in the medical profession, which possesses many members who scoff at the germ theory of disease and deride the antiseptic treatment of wounds.

What we veterinary surgeons ask is, that before we are gratuitously attacked in medical and other journals by *medical men*, some inquiry as to facts should be made, and if it be then found that we are open to censure, we shall be treated with that measure of charity with which the medical profession can, in its own case, so ill afford to dispense. The enemies of the medical profession are numerous and powerful, and it seems a pity that it does not use greater efforts to work, so far as its interests allow, with the veterinary profession, which is one of its most loyal and unselfish allies. I am, Sirs, yours faithfully,

London, June 27th, 1887. JAMES LAMBERT, F.R.C.V.S.

UBSTANTIVE *VERSUS* HONORARY RANK.

To the Editors of THE LANCET.

—Notwithstanding that the editor of the *British* *l Journal* has received two or three telegrams from th intry assuring him that "the officers of the Medical S India thoroughly agreed with him in his action on th tive rank question," I think that, were it put to the vo t would be found that the general opinion of the D ment is more in favour of the views expressed in the ed l note and in "A. M. D.'s" letter in your journal of M th, received here by last mail, than of those so per- si y upheld by your contemporary. I am not aware of ho he general opinion of the Department in India" was ar at by the gentlemen who sent the telegrams. Al gh I have made it a point to inquire, I have not yet m officer whose opinion had been asked. No doubt the gr ies at the different stations from which the tele- at (were sent, influenced a good deal by the senior officers to p places, were in favour of sending them; but it seems th that they took upon themselves a good deal more fo e circumstances of the case warranted in answering ca e Medical Staff in India." We require a rank for purposes; it is necessary to us as military officers, as have got it laid down by warrant, and our chief, Si mas Crawford, has expressed himself satisfied with it as id down. Let us, then, hope and endeavour to gain m and influence rather as physicians and surgeons than as orary majors." I am, Sirs, yours obediently,

June, 1887. M. S.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

NEWCASTLE ROYAL INFIRMARY.

er Majesty's command this infirmary is in future to be he Royal Infirmary for the counties of Newcastle-on- orthumberland, and Durham. The House Committee nfirmary has lately brought before the Sanitary Com- of our Corporation an exhaustive statement showing st aber of cases arising from drunkenness and violence Ty astle, and brought to the infirmary. The committee of hat these cases entail an annual cost of about £150, the Town Council to recompense the infirmary for th day, seeing that the council are responsible for the ance of public order and the health of the city. Th ter is to come up for further consideration, but I do as k that the council will entertain the proposal in a fa manner. Mr. Page, in a case of torticollis fol- lo obscure injury to the neck from a football ac has lately cut down on and stretched the spinal th nerve. I hope in a future letter to let you know s of the operation.

TYNE PORT.

meeting of the Tyne Port Sanitary Authority it ed that during the months of April and May there spected 1156 British steamers, 623 British sail- , 246 foreign steamers, and 203 foreign sailing ing a total of 2218 ships inspected. Notices or orders given to remedy sundry sanitary British steamers, 16 sailing vessels, 8 foreign 18 foreign sailing vessels, all of which had the exception of three, which are to be

IN THE COUNTY OF DURHAM.

County Asylum, Sedgefield, has been so over- the great influx of lunatics as to necessitate last week of 100 patients, 50 male and Lancashire County Asylum, Whittingham, Prestwich Asylum for Newcastle at Cox- gates full, and there is difficulty in any class admitted.

POISONING.

Newcastle last Saturday on the , who died after a short ill- deceased was engaged in the which lead is an ingredient, and while at work he was seized with convulsions and sickness, usual in these cases. The foreman of the factory contended that, as only a small quantity of lead was used in the manufacture of green paint, the occupation was harmless, but the evidence of Mr. Brown, surgeon, was very conclusive, as he found the characteristic blue line on the gums indicative of chronic lead poisoning, so that the jury on hearing this at once returned a verdict of "Death from the effects of lead poisoning."

Newcastle-on-Tyne, June 27th.

EDINBURGH.

(*From our own Correspondent.*)

CHALMERS HOSPITAL.

A VACANCY has occurred on the staff of this important institution in consequence of the resignation of Dr. Halliday Douglas, who has for more than a quarter of a century occupied the post of honorary physician to the hospital. Several names are already mentioned as those of probable candidates for the post, among them that of Dr. Geo. A. Gibson, secretary of the Royal College of Physicians of Edinburgh, lecturer on Materia Medica in the Extra-academical Medical School, and formerly for many years clinical tutor in the medical wards of the Royal Infirmary. Dr. J. Graham Brown is also said to be in the field as a candidate for the appointment, having already been connected with the institution in the capacity of resident surgeon some years ago. The office is one of great value from the opportunities of clinical observation which it affords. It differs, however, from similar posts in other hospitals in the absence of clinical teaching, which was specially provided against in the terms of foundation of the institution. It cannot therefore be looked upon as a component part of the Edinburgh teaching school; nevertheless, the value of the appointment in the direction indicated is such as to make it an object of ambition for men of such prominence as those mentioned, and for others whose names are not in the meantime so definitely spoken of as candidates.

THE JUBILEE HONOURS LIST.

While the sincerest satisfaction is universally felt at the added honours that have fallen to the lot of Sir Arthur Mitchell, K.C.B., and Sir George Macleod—honours that are felt to be no less becoming than they are well merited,—there has been a good deal of surprise at the abrupt termination of the list, which it was anticipated would have been somewhat lengthy. It is felt, however, that it is at present premature to give expression to any feeling of disappointment; but that it is more appropriate to consider the present list as an earnest of good things still to come, and to rejoice that places in the van of the expected marshaling of honours have been reserved for two so thoroughly worthy of that distinction.

EDINBURGH UNIVERSITY.

The final professional examinations for graduation in medicine are now in progress. Over 270 candidates have entered for the examination, and the oral part of the testing process occupies several hours each day. From the large proportion—three-fourths—of passes in the lists published up to the present, it would appear that the examiners are fortunate this year in meeting with a large average of well-prepared candidates for the degree. It is probable that August 2nd will witness the launching of over 200 fresh graduates on their voyage in search of professional success, each with the *imprimatur* of the Edinburgh Medical Faculty as the title-page of his professional log-book. Many of these graduates will doubtless find useful spheres in the colonies, from which, it is stated, fully one-third of our students are derived.

ROYAL HOSPITAL FOR SICK CHILDREN.

In consequence of Dr. Andrew's retirement by rotation from the staff of this hospital a vacancy occurs in the junior division of the honorary staff. Several candidates have presented themselves, and an energetic canvass is now proceeding in relation to the appointment. Among the competitors are Dr. John Thomson, formerly resident physician at the Great Ormond-street Hospital for Sick Children; Dr. Neal Paton, examiner in Physiology in the University

Digitized by Google

of Edinburgh, and formerly a resident physician in the Sick Children's Hospital; Dr. Felkin, well known for his scientific observations in Central Africa; and Dr. Haig Ferguson.

ROYAL MEDICAL SOCIETY.

This ancient Society, which has been possessed of a Royal Charter for over a century, held a Jubilee banquet last week in honour of the fiftieth anniversary of Her Majesty's reign. It was largely attended, and the proceedings were loyal and enthusiastic throughout. A loyal and dutiful address to Her Majesty recently presented by the Society was read by Dr. Taylor, the senior President, when proposing the toast of the Queen, and at the same time a telegram was forwarded to Sir H. Ponsonby, expressing the loyal devotion of those present who had assembled to do her honour.

Edinburgh, June 28th.

DUBLIN.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS.

AN address from the Council on the occasion of Her Majesty's Jubilee will be presented at Windsor this week by the President of the College, Mr. A. H. Corley.

UNIVERSITY OF DUBLIN.

At the annual meeting of the Senate last week the following grace, proposed by the Provost and senior Fellows, was adopted:—"1. Ad Baccalaureatum in Arte Obstetricia nemo admittatur qui prius Baccalaureatum in Medicina non susceperit. Priusquam gratia ejus proponatur, Candidatus a Professoribus Medicis in aula publica solenniter examinetur, atque idoneus comperiatur. 2. Formula supplicandi pro gradu Baccalaureatus in Arte Obstetricia R. R. Cancellarie, totaque universitas supplicat reverentiis vestris N. N. ut Baccalaureatus in Medicina, una cum omnibus exercitiis et examinationibus per leges et consuedines Academiæ requisitis, sufficiat et ad respondendum in Arte Obstetricia." This is a new degree of Bachelor in Midwifery, which has become necessary by the passing of the Act of 1886. The University law required candidates for the degree of Master in Midwifery to be a Master of Arts, and by the grace now adopted it will be sufficient for the candidate to be a Bachelor in Arts.

JUBILEE HONOURS FOR THE PROFESSION.

The marked absence of any distinctions to members of the profession in Ireland, at all events up to the present, while honours have been conferred on their English and Scotch brethren, must be regarded with extreme disapproval. The bad taste shown by ignoring their claims to Jubilee honours can scarcely be disputed, and although a supplementary "Jubilee Gazette" has been talked of, the most sanguine can hardly imagine that the names of any Dublin physician or surgeon will be included in the list of honours.

THE SANITARY CONDITION OF THE DUBLIN BARRACKS.

For several years past the insanitary condition of most of the Dublin b arracks, more particularly the Royal and Richmond, has attracted considerable attention, in consequence of the repeated deaths from typhoid fever which have occurred among men and officers. The military authorities, however, persistently denied that the sewerage arrangements were in any way defective, and so matters have been allowed to go on up to the present. Lord Beauchamp, it is satisfactory to learn, has now drawn attention to the matter, and last week in the House of Lords moved for a return of all cases of febrile and respiratory diseases which have occurred in the Dublin garrison since Jan. 1st, 1881, and which, after some discussion, was agreed to. The argument of Lord Harris in objecting to the return, to the effect that the death-rate among the garrison was lower than that of the civil population, is altogether outside the the question, as it is evident that the mortality among lower classes in this city is inevitably much higher than among a picked body of men like soldiers. It appears that the Secretary of State for War, as mentioned by me some months since, has directed an examination of the sanitary state of the Royal Barracks by Sir Charles Cameron, Medical Superintendent Officer of Health for Dublin, and Dr. Grimshaw, Registrar-General for Ireland, in conjunction with the Principal Medical Officer, which examination is now being carried out.

MERCER'S HOSPITAL, DUBLIN.

On Saturday last the Vice-Chancellor fixed the hearing of a motion made by Mr. Edward Stamer O'Grady, a well-known Dublin surgeon, for an injunction to restrain the governors of Mercer's Hospital and Dr. C. F. Knight from removing him from the surgical staff of that institution. The case will be heard on Monday next.

HOSPITAL FOR INCURABLES.

The foundation stone of the new Victoria Jubilee buildings at this hospital will be laid on the 29th by His Royal Highness Prince Albert Victor. The buildings are to be on the pavilion system, and will include special accommodation for patients suffering from phthisis and other affections of the respiratory system. The wards will be sheltered on the north and east, and will be heated by hot-water pipes as well as by open fireplaces. Ventilation will be carefully attended to, and all modern sanitary arrangements adopted.

ADELAIDE HOSPITAL, DUBLIN.

The Hudson Scholarship this year has been awarded to Thomas E. Dunne, and the Hudson Prize to Christopher Healy. The Scholarship consists of a gold medal and £30, and the Hudson Prize of a silver medal and £10.

CASE OF CONGENITAL GOITRE.

There is at present in Mercer's Hospital, under the care of Dr. C. F. Knight, an example of congenital goitre. The patient is a boy about a fortnight old, and both lateral lobes are enlarged. The mother has suffered from goitre for the past two years.

PARIS.

(From our own Correspondent.)

THE SEQUESTRATION OF BARON SEILLIÈRE.

A WELL-KNOWN member of society, Baron Seillière, has been somewhat hurriedly transferred to the *maison de santé* (as lunatic asylums are more discreetly termed in France) of the celebrated Dr. Falret. A sharp controversy has arisen in the press in consequence of this sequestration, and many of the writers are loud in denouncing the state of the law on the subject, and in abusing all those concerned in administering it. Baron Seillière bitterly complains of the whole proceedings. He declares his family laid a plot to entrap him. "I may have been eccentric, I may have spent money freely, but many a man in my position has done the same. If I have made bad speculations, I have also made successful ones, and as I neither think, speak, nor write as a madman, I consider myself the victim of an unjustifiable attack." On the other hand, Professor Charcot, who has interviewed the patient on behalf of his family, declares him to be insane. As I have already hinted, the comments of the press upon mental physicians and their doings are far from complimentary; and although there is no doubt a great deal of exaggeration, some of the statements made are not entirely devoid of foundation. It is an aphorism amongst French alienists that any person in Paris presenting signs of excitement should, in the absence of a satisfactory explanation, be suspected of general paralysis. Not only are the Parisians privileged in counting in their number the highest percentage and the most eminent sufferers from the *maladie du siècle*, but it is said also that Paris has a special attractive influence for general paralytics as a class. Given, then, a person in a state of excitement, he would, if he had the misfortune to be examined by an expert, run a very fair chance of being sent to an asylum. Once there, any explosion of indignation would be taken as additional evidence of the necessity of the measure, and if the victim were not calmed by being cut off from the world, and soothed by the application of a *camisole de force*, no sane alienist would entertain any further doubt as to the nature of his case. The lawyers maintain, and this is the practical outcome of the whole matter, that the *affaire Seillière* shows the urgent necessity of a change in the present law concerning the insane. As it is, they say, once a man has fallen into the hands of the alienists, the machinery of the

Digitized by Google

law is powerless to help him. He may, at the discretion of his keepers, be separated from the whole world, and even subjected to solitary confinement. Should those interested in his welfare think they have cause to complain, they are hardly able to obtain an independent examination. Those who have the patient in charge can refuse access to all except the expert commissioned by the courts in each particular instance; but as in lunacy practice the expert of to-day is often the alienist of to-morrow, the patient may benefit but little by such a consultation.

PASTEURIANA.

The Secretary of the Academy of Medicine states that the letter read by M. Peter some time back containing the unfavourable results of Cantini's inoculations, and purporting to have been written by Professor Tommasi, was apocryphal. In consequence of this letter M. Cantini had sent in his resignation as Member of the Royal Academy of Naples; but now that matters are explained, and it turns out that M. Peter was hoaxed, M. Cantini has, at the desire of his colleagues, withdrawn his resignation. M. von Frisch writes to the *Semaine Médicale* to claim the priority of the idea of testing the value of the preventive inoculations by previous intracranial inoculation. In his letter to the Vienna Society, which I mentioned last week, M. Pasteur declared that he had spoken of this to M. von Frisch, as he had to Professors Burdon Sanderson and Victor Horsley, and that it must be a slip of the memory on the part of M. von Frisch to attribute the idea to himself. In his letter to the Paris journal M. von Frisch denies this "in the most absolute manner." "If," writes he, "M. Pasteur will not allow that his pretensions are based upon an error of memory on his part, I shall be forced to repudiate with indignation this attack, so unjustifiable and so derogatory to my scientific honour." It is evident that the controversy is likely to enter into a still more acute period, and the report of the English experimenters, which is looked forward to with the greatest interest, would just now come at a most seasonable juncture. According to the official report of M. Labully, fifty-three persons were bitten by mad animals during the year 1886 in the department of the Loire. Of these twenty-six were treated at the laboratory without a death. One death took place amongst the remainder, but, according to the *Semaine Médicale*, none of those who underwent a mystic ceremony, in which an omelette plays an important part, have had reason to regret their confidence.

SALINAPHTHOL.

Salol is a compound body formed of salicylic acid and phenol, which is decomposed into its constituents in the intestine. Professor Lépine advocates the substitution for it of a new compound, obtained by M. Merk, and which has been called naphthol-salol, naphthalol, &c., and for which he proposes the name salinaphthol:

$$C_6H_4.OH.CO_2H + C_{10}H_7.OH = C_6H_4.OH.CO.OC_{10}H_7 + H_2O$$

Salicylic acid + β-naphthol = sali-naphthol + H_2O.

Like salol, the efficacy of the new drug depends upon its decomposition in the intestine by the pancreatic secretion, and it is therefore inert and unirritating in the stomach. The advantage claimed for it over salol is that when split up into its component parts there remains besides the salicylic acid, which is the therapeutic agent, a by-product, β-naphthol, which is less toxic and less absorbable than the phenol which results from the decomposition of salol.

WATER-SUPPLY OF PARIS.

The Municipal Council has decided that whenever it should be necessary (and this is nearly always the case) to distribute typhogenic drinking water to some quarters of Paris, the supply of bad water shall in future be made to these districts inhabited by the wealthy. It was added that this substitution shall, however, be subject to the approval of the sixth commission. As a general measure, it may be wiser to expose the richer and healthier quarters to the dangers of typhoid, than to induce it with certainty in those which are overcrowded, but it is to be hoped that no change will be allowed to be made without a notice being sent to every interested party.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The annual general meeting of this Society will be held at the rooms of the Medical Society of London on July 27th, under the presidency of Dr. F. Needham.

VIENNA.

(From our own Correspondent.)

PASTEURIANA.

SOME weeks ago the results of Professor von Frisch's experiments on rabies were published by him in a book entitled "The Treatment of Rabies." Professor von Billroth felt himself compelled to strengthen the authority of his pupil by an article in a Vienna newspaper, in which the Pasteurian mode of treatment of splenic fever and of rabies was wholly condemned, and the book of Professor von Frisch was eulogised as a work bestowing new prestige upon our Vienna school. According to Billroth's opinion, it has been proved by Professor von Frisch that the value of Pasteur's preventive inoculations in man and in animals is problematical, and that it is possible by Pasteur's treatment that thoroughly healthy persons may be artificially made rabid. The charges brought forward by Professor Billroth caused M. Pasteur to send a letter to the Vienna Society of Physicians refuting the statements of the former. This letter was read at the meeting of the Society on June 10th. To prove the value of his method in the prevention of splenic fever he alluded to the results obtained by his inoculations in France, as shown by the following statistics of inoculated sheep and cattle. The mortality of non-inoculated sheep is 10 per cent.

Year.	Sheep.	Mortality.
1882	29,3199	1·08 per cent.
1883	19,3119	0·77 ,,
1884	23,1693	0·97 ,,
1885	28,0107	0 90 ,,
1886	20,2064	0·75 ,,
Year.	**Cattle.**	**Mortality.**
1882	22,916	0·35 per cent.
1883	20,901	0·35 ,,
1884	22,616	0·37 ,,
1885	21,703	0·50 ,,
1886	22,113	0·28 ,,

In non-inoculated cattle the mortality amounts to 5 per cent. Referring to the claim of priority made by Professor von Frisch, and supported by Professor Billroth, M. Pasteur in his letter states that he had communicated personally to Professor Frisch during his stay in Paris the results of experiments on preventive inoculations in dogs infected artificially by subdural injections with street rabies, which had not then been published. The same communication was made at the same time to the members of the British Committee (Professors Burdon Sanderson and Victor Horsley) and to Dr. Gamaleia of Odessa, who on June 6th, 1886 (before Frisch's first communication), at a meeting of physicians of Odessa said: "It was shown by M. Pasteur that in some cases, even after subdural infection, the outbreak of rabies could be prevented." In reference to another statement of Professor von Frisch, M. Pasteur claimed success in preventing the outbreak of rabies in dogs subjected to subdural infection; and these experiments, repeated by Dr. Bardach of Odessa, gave also the best results in ten cases out of seventy-five. But these experiments were only made as an *argumentum a fortiori* for Pasteur's treatment; while Frisch maintained that the value of Pasteur's method could only be proved by subdural infection followed by preventive inoculations. The experiments of Frisch, states M. Pasteur, were carried out inexactly; and while he made his experiments on dogs, the experiments of Frisch were made on rabbits. Frisch also failed in consequence of the slow process of inoculations adopted by him. In closing his letter, M. Pasteur laid stress on the positive results of his experiments, showing that even after subdural infection the animals can be made refractory by inoculations. Professor von Frisch denied the statements made in Pasteur's letter. He said that Professor Billroth was right in asserting that Pasteur had made a *fiasco* with his preventive inoculations for splenic fever, as could be seen by the publications of the Berlin School and by the refusal of the English Government to introduce Pasteur's method into England. As regards the rabies question, he denied that M. Pasteur had made to him any communication on the subdural infection experiments, and endeavoured to refute the objections made against his experiments.

DR. ULLMANN ON THE PREVENTIVE INOCULATIONS IN HYDROPHOBIA.

Dr. Ullmann, assistant of Professor Albert, has carried out Pasteur's treatment at the surgical clinics for some twelve months, during which time 118 persons have been treated. Of these, three persons died from hydrophobia; the others remained healthy. Dr. Ullmann is also carrying out experimental researches on animals, and at the last meeting of the Vienna Society of Physicians a preliminary note was read by him containing the following conclusions: (1) According to his experiments thus far, the animals do not succumb from rabies in consequence of preventive inoculations; (2) certain animals can be rendered refractory against rabies by preventive inoculations; (3) the statistics of preventive inoculations made by him in human beings are also favourable to the value of Pasteur's method.

THE PHOSPHATE OF LIME TREATMENT IN LOCAL TUBERCULOSIS.

Dr. Kolischer was at first of the opinion that it might be possible to produce calcification in tuberculous tissues by local application of strong solutions of lime. Strong solutions of calcic chloride, of carbonate of lime in water containing carbonic acid, and of neutral phosphate of lime in common salt solution, were used without result, till Herr Ernst Freund, who had some time ago discovered the presence of cellulose in tuberculosis, proposed to use primary phosphate of lime or calcium monophosphite, which is prepared by dissolving phosphate of lime in water, by slowly adding phosphoric acid. The following prescriptions are used:—

1. For injections (containing 1 per mille phosphoric acid): R. Calc. phosphor. neutr., 5·0 grammes; aq. destill., 500·0. Deinde sensim adde: acid. phosp. dil., 0·6; aq. dest. quant. suf. ad 100·0. 2. For impregnating the gauze (containing 1 per cent. phosphoric acid):—R. Calc. phosphor. neutr., 50·0; aq. destill., 500·0. Deinde sensim adde: acid. phosphor. q. s. ut fiat solutio perfecta, filtra. Adde: acid. phosphor. dil., 60·0 (120·0); aq. destill. q. s. ad 1000·0.

In torpid cases a stronger solution for impregnating the gauze is used, containing 120·0 grammes acid. phosphorici (instead of 60·0). As I am informed by Herr Freund, he recommended this solution as a result of chemical analysis of the blood of tuberculous persons, carried out by himself in Professor Ludwig's laboratory. It seems that phosphoric acid is the real active principle of this solution.

Vienna, June 11th.

THE SERVICES.

Surgeon-General T. W. Fox, M.B., has assumed the duties of Principal Medical Officer at Aldershot in succession to Surgeon-General J. Hendley, C.B., who is about to be placed on the retired list.

Deputy Surgeon-General R. A. Chapple has joined at Mhow from Bombay for duty.

WAR OFFICE.—Army Medical Staff: Deputy Surgeon-General Thomas William Fox, M.B., to be Surgeon-General, vice A. H. Fraser, retired (dated May 18th, 1887).

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Staff Surgeon John Wood has been placed on the retired list of his rank (dated June 11th, 1887).

INFANTRY MILITIA.—5th Battalion, the Royal Munster Fusiliers: Surgeon-Major P. Enright, M.D., resigns his commission; also is permitted to retain his rank, and to wear the prescribed uniform on his retirement (dated June 25th, 1887).

ARTILLERY VOLUNTEERS.—1st Newcastle-on-Tyne: M. J. Wakefield, M.B., to be Acting Surgeon (dated June 25th, 1887). 2nd Volunteer (Sussex) Brigade, Cinque Ports Division, Royal Artillery: Surgeon R. V. Skinner resigns his commission (dated June 25th, 1887); Acting Surgeon H. Colgate, M.D., to be Surgeon (dated June 25th, 1887).

THE VOLUNTEER MEDICAL STAFF CORPS.—The London Division: Surgeon Richard Lake resigns his commission (dated June 25th, 1887).

ON the 25th ult. a dinner was held in connexion with the Edinburgh Royal Medical Society, Dr. James Taylor, senior president, in the chair.

Medical News.

Lovitt, Robert James, Wells-road, Hampstead.
Petit, Charles Frederick Newton, Camden-street.
Read, Thomas George, Cavendish-square.
Robinson, Charles Cecil, Broadway, Streatham.
Rymer, James Francis (M.R.C.S. Eng.), Pevensey, Croydon.
Seymour, George, St. Augustine's-road, Camden-square.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At Examinations recently held the following out of the eighteen candidates who entered passed the first half of the examination for the Letters Testimonial of the College, under the old scheme regulations:—

Ninian N. S. Blackham, Daniel Connor, Walter B. Croker, William F. Dillon, Francis O'Mara, Daniel Power, and James F. McMonagle.

SOCIETY OF APOTHECARIES.—The following gentlemen having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received Certificates entitling them to practise as Licentiates of the Society on June 23rd:—

Archer, E. Richard Barnes, Donegal-terrace, Stoke, Devonport.
Black, George, Pembroke-road, Walthamstow, Essex.
Claremont, Constantine Cecil, Millbrook House, Hampstead-rd.
Green, George Sydney, Kelvedon, Essex.
Johnson, John Mountfort, Roche-terrace, Leek.
Owen, David, Fenwick-street, Hulme, Manchester.
Rhodes, Harvey, Long-street, Middleton, Manchester.
Ward, Howard Percy, Silverbeck, Hanwell, Middlesex.

The class list of the Arts Examination of the Society of Apothecaries has just been published. The total number of candidates, it appears, was 201. One candidate is placed in the first class, and 35 in the second. Of the remainder, 124 passed in one or more subjects, but not in all; and 41 failed to reach the required standard in any subject.

At the recent examination for the Prizes in Botany given annually to medical students by the Society, the successful candidates were the following:—

1. Helbutt Jacob Waring, St. Bartholomew's Hospital. Gold Medal.
2. Charles Arthur Kent, University College. Silver Medal.

Prizes in Botany also are given annually to young women under twenty years of age; of whom the successful candidates were the following:—

1. Sophie Margaret Fedarb, Whiteland's College, Chelsea. Gold Medal.
2. Ella Oswald, Regent's Park College. Silver Medal.

Six candidates were awarded certificates of merit.

THE recent Hospital Saturday collection in Hull has realised £286, against £311 last year.

THE TARIFF OF MODERN DRUGS.—The Spanish College of Pharmacists has appointed a committee to report upon the newer pharmaceutical preparations which are not included in the official tariff, in order that the prices at which they are dispensed may be definitely fixed.

AN inquest was held on the 23rd ult. at Colney Hatch Asylum upon the body of an inmate who had died from poisoning by carbolic acid, administered through a mistake of the dispenser. The jury returned a verdict of death by misadventure.

MEDICAL MAGISTRATE.—The Lord Chancellor has placed the name of Mr. H. J. Lloyd, L.R.C.P., &c., Ty'nycoed [illegible] upon the Commission of the Peace for the county of Merioneth, and was qualified at the Quarter Sessions held at Dolgelly on the 28th inst.

[illegible].—Mr. F. W. Alexander has been presented with a writing cabinet, a liqueur case, and an [illegible] by the officers and staff of the Mile-end Old [illegible] upon his resigning the post of assistant [illegible] institution.

[illegible] OF THE THAMES.—On the 29th ult., [illegible] Justice's Court, the grand jury found a true [illegible] Local Board of Staines for polluting the [illegible] of the town. The prosecutors are the [illegible] the Thames.

[illegible] has been presented to the [illegible]-Pharmaceutical Academy of [illegible] may be drained, as the [illegible] malarial fever which is so [illegible].

H.R.H. Princess Beatrice will present certificates to the Polytechnic classes of the St. John Ambulance Association on July 6th.

TRIESTE HOSPITAL.—£6000 has just been left to this institution by the deceased Herr Esser; £1000 of the legacy is to be applied towards building a Convalescent Home on the Kockelsberg.

SUPPOSED SUICIDE NEAR LEEDS.—On Wednesday morning last a man was found dead, with a bottle labelled "poison" by his side, on Calverley-moor, near Leeds. The deceased has since been identified as a member of a Volunteer Corps.

ON the 25th ult. the King of the Belgians paid a visit to the East London Hospital for Children at Shadwell, and on his departure from the institution expressed his satisfaction at the condition of the hospital, and announced his willingness to become a patron of the institution.

THE DROUGHT.—The prolonged drought is beginning to be inconveniently felt in different parts of the country. At Swansea the scarcity of water is such that the water committee are taking steps to utilise the water in a large disused colliery.

CHARING-CROSS MEDICAL SCHOOL.—On the 28th ult. Sir John Lubbock, M.P., presided at the distribution of medals, prizes, and certificates gained by the students of this school during the summer session of 1886 and the winter session of 1886-7. The annual report read by the Dean was of a highly satisfactory character.

HOSPITAL SATURDAY FUND.—At a meeting of the delegates of the Hospital Saturday Fund, held on Saturday evening at 41, Fleet-street, the Secretary reported that the recent street collection reached nearly £5000. The Dean of Westminster had forwarded £410, being one-sixth of the net proceeds of the service at the Abbey on the 22nd ult. on behalf of the London hospitals.

HOSPITAL AT TEHERAN.—The Shah of Persia has authorised the American missionaries to establish at Teheran a hospital in which, without regard to nationality or religion, all applicants for relief may be received for treatment. Dr. Torrence, physician to the mission, has been appointed director of the hospital, and the Shah has named him Grand Officer of the Order of the Lion and the Sun of Persia.

OPEN PRIZE COMPETITION.—The Medical Institute of Valencia, offers gold medals for the best works on the following topics:—1, Chorea; 2, Ovarian Tumours; 3, The Medicinal Plants of Valencia; 4, Any scientific subject at the option of the author. The essays, which may be written in English, are to be sent to the "*Secretario de Gobierno calle del Triador*," No. 11, by December 1st, 1887. The announcement of the results will take place on March 31st, 1888. The competition is open to medical men and pharmacists of all nationalities.

THE GOVERNMENT AND EDUCATIONAL GRANTS.—A deputation waited upon the Chancellor of the Exchequer on Thursday last to urge upon him their views on the subject of Government assistance to university colleges in England. They drew the attention of the Chancellor of the Exchequer to the fact that the local support given to university colleges in many of the largest centres of population in England has been inefficient, and they urged that these colleges have strong claims for Government aid to supplement local efforts, precedents for such grants being already established by the aid given to colleges in Scotland, Ireland, and Wales. It was pointed out that Wales, with three centres and an aggregate population within twenty miles of those centres of 452,000, enjoys grants of £12,000; Scotland, with five centres (1,260,000), £16,675; and Ireland, with three centres (400,000), £24,500; while England, with ten centres where local collegeges exist, with an aggregate population in the neighbourhood of nearly 12,000,000, receives absolutely nothing from Government. The claims of these colleges are based on their services in education in literature and pure science, higher technical instruction, and higher popular education. The deputation suggested that such grants should be applied partly in direct grants and partly in exhibitions. Mr. Goschen assured the members of the deputation of his deep interest in the educational question, and that their views would have every consideration.

SAD ACCIDENT.—On Wednesday, whilst a party of nurses of the Leeds Infirmary were proceeding in waggonettes to Bolton Woods for their annual excursion, the horses attached to one of the vehicles became unmanageable, and the conveyance was upset. The majority of the occupants were thrown out. Five were seriously injured, and had to be conveyed as patients to the institution where they were accustomed to act as ministrants to the sick, whilst others sustained slighter injuries.

SWINE FEVER AND PLEURO-PNEUMONIA IN KENT.—The returns from the Kentish authorities on the 28th ult. show a further extension of swine fever, fresh cases having occurred at Crayford, Dartford, Teynham, and Tunbridge. During the last ten weeks pleuro-pneumonia has broken out at Cowden, and eighteen affected animals and three healthy animals that had been in contact with some so affected have been slaughtered, the sum of £292 having been paid to the owners in compensation. The compensation for the slaughter of animals affected with swine fever during the same period has amounted to £603.

MEDICAL NOTES IN PARLIAMENT.

Sanitary Condition of Dublin Garrison.

IN the House of Lords on the 23rd ult. Earl Beauchamp moved for a nominal return of all cases of febrile and respiratory disease which had occurred in the Dublin garrison since Jan. 1st, 1881, distinguishing in each case the barracks.—Lord Harris reminded the noble Earl that barracks were about to be erected on another site in Dublin, and £15,000 had been taken for that service in the estimates for the present year. As soon as the whole of the ground was obtained—there had been some legal difficulties with regard to a part of it,—cavalry barracks would be erected, and the Royal Barracks, Dublin, with regard to which there might possibly be some suspicion of insanitary condition, would be remodelled and used only for infantry. In the barrack annual estimates of this year a sum of £1089 was taken for specific improvements at the Royal Barracks, and £600 for various sanitary purposes in the Dublin barracks generally.—The Earl of Carnarvon trusted that the Government would apply themselves to remedy the insanitary condition of the Royal Barracks, the question being one of a most serious character.—Viscount Powerscourt agreed with the noble lord, the late Lord-Lieutenant of Ireland, as to the state of the Royal Barracks. He knew as a fact that the barracks in Dublin had for many years been in a very insanitary condition.—The motion was agreed to.

Dog Regulations.

In the House of Commons, in reply to Sir J. Commerell, Mr. Matthews stated that the rabies order of 1886 enabled local authorities from time to time to make regulations as they thought fit for the regulation of dogs. Such regulations, when made, only applied to the district of the local authority by whom they were made. The anomaly in the suburbs of the borough of Southampton, which were in the county of Hants, by which on one side of the street dogs might roam about unmuzzled and not under control, while on the other side of the street such liberty was an offence, was apparent, but there was no means of avoiding it, as he had no power to alter the boundaries of local authorities.

Coal Mines Regulation Bill.

The House went into committee upon this Bill, resuming the discussion of the amendment to Clause 8, the object of the amendment being to exclude girls from the operation of the clause, and so to prevent them from being employed. After a long discussion the amendment was rejected by 188 votes to 112. It was decided that no boy under twelve years of age nor girl under fourteen should be permitted to work. Other clauses, one of which rendered it compulsory for the owner, agent, or manager of every mine to keep a register of all boys, girls, and women employed in connexion with the mine, were passed, and progress reported.

On the 24th ult., the House again went into Committee on the Bill, and several clauses relating to the position and duties of the check weighers, the position of the shafts or outlets, the adequate provision of appliances for ventilation and apparatus for ascending and descending the shafts were adopted. A discussion then followed on the management of mines, which was not concluded at the hour when by the rules of the House the debate stood adjourned.

Vaccination.

On the 24th ult., in reply to Mr. Bradlaugh, Mr. Ritchie said that he was aware that in several towns, parts of towns, and villages, associations for the abolition of compulsory vaccination have issued forms in which questions have been submitted with reference to vaccination, but no precise information as to the mode in which the inquiry was conducted or in how many cases the persons applied to declined to fill up the forms distributed by those associations. No doubt the returns which have been made by the associations referred to represent that a considerable majority of those who have thought fit to fill up the forms have stated that they were opposed to vaccination. No one was more desirous than himself that vaccination should be performed with due care, and he might mention that revised instructions to vaccinators had been recently issued with a view to securing every requisite precaution in vaccination. For reasons which he had more than once stated in the House it was not his intention to propose a public inquiry.—In reply to Mr. Channing, Mr. Ritchie stated that he was aware that in some towns the provisions of the Vaccination Acts were not carried out in the same entirety as in others, but that was no reason why they should alter the law as it now exists. It was not his intention, in connexion with the Local Government Bill or otherwise, to propose any alteration of the existing law as to vaccination.

Holyhead Union.

In answer to Mr. Lewis, Mr. Ritchie said that it was the case that Dr. Harvey, who was acting as a medical inspector of the Local Government Board, visited the Holyhead Union with a view of reporting on its sanitary condition and the prevalence in the district of enteric fever and diphtheria. The Board had not declined to sanction the appointment of the medical officer of health, but they were clearly of opinion that he ought to devote more time to his duties than heretofore. Dr. Harvey is not now in the service of the Board, and since notice of the question was given Mr. Ritchie had been unable to communicate with him as to the precise time devoted to his inspection and the numbe of houses visited by him. There was no reason whatever to doubt that he devoted as much time to the inquiry as was necesary to enable him to ascertain the facts required to be reported to the Board as to the sanitary condition of the district. The sanitary authority have applied to the department for a copy of Dr. Harvey's report, and the Board on the 14th ult. furnished them with a full copy of so much of the report as referred to the sanitary condition of the district.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ABELE, CHARLES JOSEPH, M.B., M.R.C.S., has been appointed Resident Medical Officer to University College Hospital.

ATKINSON, JOHN M., M.B.Lond., M.R.C.S., has been appointed Medical Officer for the Third District of the St. Mary Abbott's, Parish of Kensington, Union.

BARON, BARCLAY J., M.B., C.M.Ed., has been appointed Lecturer on Practical Pathology and Morbid Anatomy at the Bristol Medical School.

Medical Diary for the ensuing Week.

Monday, July 4.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

Tuesday, July 5.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

Wednesday, July 6.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Steavenson, Dr. Horrocks, and others.—Adjourned discussion on Dr. Walter Griffith's paper on Tubo-ovarian Cysts.—Dr. Matthews Duncan: Diabetes Insipidus in Women.—Dr. Champneys: (1) Some Causes of Retention of the Membranes; (2) Note on the Relation between the Position of the Placenta and the Insertion of the Cord.

Thursday, July 7.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—4 P.M. Report of Council. Professor Alex. Macalister: A Note on Some Common Errors in Descriptions of the Brachialis Anticus Muscle.—Dr. Brooks (Dublin): On the Short Muscles of the Pollux and Hallux of the Anthropoid Apes, with special reference to the Opponens Hallucis (with specimens).—Mr. J. Bland Sutton: A Critical Study in Cranial Morphology.—Messrs. Rickman J. Godlee and C. Stonham: Casts of Bronchi.—Mr. James Berry: Notes on the Anatomy of the Thyroid Body (with specimens).—Mr. W. Bruce Clarke: Apparatus for Mounting Specimens.—Dr. W. J. Collins: Anatomical Specimens.—Mr. Lockwood: Cases for Mounting Frozen Sections.—Professor Curnow: Abnormal Subclavian Artery (with specimen).

Friday, July 8.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Election of office bearers. Living and card specimens at 8 P.M. Mr. W. Spencer Watson: (1) Sequel to a case of Hæmorrhagic Glaucoma (with specimen); (2) Case of Serpiginous Nebula of Cornea.—Mr. Lawford: A case of Ophthalmoplegia Externa.—Mr. J. Hutchinson, jun., and Dr. Robinson: Case of Ophthalmoplegia Externa, with Autopsy.—Mr. Cross (Bristol): Sympathetic Ophthalmitis occurring after Evisceration.

Saturday, July 9.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

"A WORM IN AN EGG."

THE specimen (see THE LANCET, June 18th, page 1269), after being immersed in water for several days, was carefully examined. It had a superficial resemblance to a tapeworm, being about two inches and a half in length and a quarter of an inch in width at its posterior truncated extremity, there being, further, an appearance of a head at the opposite extremity. Moreover, it had an obscurely segmented character. The microscopic examination did not bear this surmise out; for it showed the mass to be quite structureless, and infiltrated with lime salts in its outer layers, which were laminated. It is much to be regretted that the specimen was not placed in a preservative solution as soon as it was obtained, as it had doubtless undergone considerable change from desiccation.

Dr. Wedgwood.—The Anchor line plying from Glasgow to New York offers to members of the profession return tickets to the United States capital for £20.

Surgeon and Apothecary might try bismuth, hydrocyanic acid, &c., and feed the patient frequently on small doses of iced beef-juice, milk, &c.

Mr. J. Lewtas.—In an early number.

INVERSION OF THE UTERUS.

To the Editors of THE LANCET.

SIRS,—Dr. Montagu Handfield Jones, in describing two cases of acute inversion of the uterus in THE LANCET of this week, considers that the cause of one of them was the shortness of the umbilical cord—i.e., fifteen inches. I doubt much if with this length of cord the cause he mentions could have operated. I have before me notes of two cases of short cord, in one of which the placenta was adherent high up in an elongated cornu, the cord measuring ten inches; in the other, with non-adherent placenta, it measured just nine inches and a half. In neither case was there any attempt at inversion. Indeed, in the first case the uterus was in a state of hour-glass contraction.

I am, Sirs, yours truly,

F. R. HUMPHREYS, L.R.C.P., &c.

Queen's-crescent, N.W., June 27th, 1887.

"AN URGENT CASE."

DR. GLOVER desires to acknowledge the receipt of £5 5s. towards the above case (THE LANCET, May 28th) from "W. M. B."

Mr. J. Botten.—Foreign diplomas are recognised in Turkey; but we believe some formality has to be gone through at the Military Medical School before the right to practise is fully and officially granted.

Public Vaccinator.—Unless our correspondent could show a very special and satisfactory reason for vaccinating in less than four places, he would not receive the grant.

M. Jones.—The piercing the ear may act as a counter-irritant.

THE JUBILEE BOOK OF THE CHURCH OF ENGLAND TEMPERANCE SOCIETY.

WE have just received a copy of this book, which is also a Guide-book to the bazaar now being held on behalf of the Society in the Duke of Wellington's Riding School, Knightsbridge. It is edited by the Rev. J. Grant Mills, M.A., Hospitaller of St. Thomas's Hospital, is profusely illustrated, and has been well produced by Messrs. Cassell & Co. Among the contributors are H.R.H. the Princess Beatrice, Professor Herkomer, A.R.A.; Mr. Lewis Morris, who sends an excellent poem on "Temperance," the temperance of the whole man; Edna Lyall, John Shorthouse, Mr. Molesworth, Mr. A. J. Caldecott, and Canon Ellison, who has written the history of the Society from its formation, a purely total abstinence society in 1862, to its present broad basis: "Union and co-operation, on perfectly equal terms, between those who use and those who abstain from intoxicating drinks." Special features of the book are the illustrations of the stalls, which all have reference to the diocese, county, or the various departments of the Society's work which they represent. At the end of the book there is a programme of the various entertainments to be held during the bazaar, but it will be of more than passing value as a guide during the week, from the interesting history of the Society which it contains, and its contributions from so many well-known artists and authors. The production reflects great credit on its well-known and energetic editor and those who have assisted him.

A Locum.—We think the practitioner should allow the *locum tenens* to retain the fee in such a case; but legally it is to be considered as belonging to the former. A *locum tenens* cannot be regarded as an independent practitioner.

Messrs. Woodhouse and Rawson.—A specimen of the apparatus should be forwarded for our inspection.

ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

To the Editors of THE LANCET.

SIRS,—I will thank you to be so good as to insert the underadded copy of a letter received from the Under-Secretary of State in your next issue of THE LANCET. I am, Sirs, yours very truly,

June 27th, 1887. J. HENRY RUTHERFORD, Secretary.

"Whitehall, 16th June, 1887.

"Sir,—With reference to your letter of the 18th ultimo, I am directed by the Secretary of State to acquaint you that he has laid before the Queen the application of the Governors of the Newcastle-upon-Tyne Infirmary for permission to adopt the title 'Royal' in the name of that institution, and that her Majesty has been graciously pleased to accede to their request, and to command that the infirmary be styled in future 'The Royal Infirmary for the Counties of Newcastle-upon-Tyne, Northumberland, and Durham.'

"I am, Sir, your obedient servant,

"GODFREY LUSHINGTON.

"The Secretary to the Infirmary, Newcastle-upon-Tyne."

"THE SILENCE OF DEAN MAITLAND."

IT will be interesting to many of our readers to learn that the author of the above work, which we noticed in our last issue, is the daughter of an old and much respected general practitioner in the Isle of Wight.

A Widow.—It seems probable that the unpleasant difficulty arises from some vagueness in the terms of the contract or understanding between our correspondent and her former medical attendant. A "consultation" used by a general practitioner may mean seeing a patient at the house of the medical man, as distinguished from a "visit" at the patient's house. We are not told in the letter sent us whether the charge for a visit in the original contract was to cover a visit to any number of persons, or only to one. These omissions make it impossible for us to advise dogmatically in the matter. A medical man is not generally asked for particulars, but he ought to be ready to give them when reasonable and courteous request is made. We should advise our correspondent to continue her efforts to close the account amicably. We see no good in publishing the letter, which, of course, is a one-sided statement.

Dr. G. Ria (Naples).—We regret that we cannot at present extend our exchange list.

R. M. B. should address his question to his ordinary medical attendant.

A CORRECTION.

To the Editors of THE LANCET.

SIRS,—At page 144 of my recently published "Treatise on Diseases of the Skin" there is an unfortunate printer's error. The first prescription on that page, marked with an asterisk, is for an arsenical mixture, and the dose is stated to be a tablespoonful. It should have been a *teaspoonful*. This mistake has been corrected in the copies still in the publishers' hands; but as there are no means of communicating directly with all those who have already purchased the book, I shall feel obliged if you will kindly intimate this correction in THE LANCET.

I am, Sirs, your obedient servant,

Glasgow, June 28rd, 1887. T. MCCALL ANDERSON.

THE LEMON DECOCTION IN MALARIA.

THIS remedy has, besides its anti-malarial efficacy, distinct value as a tonic to the stomach. Its preparation is thus given by Dr. Tommasi-Crudeli, who first introduced it to the profession:—Take a fresh lemon; cut it in thin slices, rind and all; boil it in three tumblerfuls of water in an earthen pot which had not been previously used for culinary purposes; prolong the boiling till the liquid contents of the pot have been reduced to one-third—that is, to the volume of one tumbler. Pass the decoction through muslin, squeezing out the residue of the lemon, and let it cool for several hours. Let the whole be taken in the early morning, fasting. "The drink," adds Tommasi-Crudeli, "is rather bitter, but not distastefully so; it is easily taken by delicate women and children, and when it has reached the stomach it induces the pleasant sensation peculiar to tonic remedies." Its use is especially indicated in the tropics.

L.S.A.—Our correspondent's certificates were ample. He should complain of the remarks of the registrar of deaths to the Registrar-General. Benefit societies are entitled to ask for a copy of the death certificate from the registrar; but it is intolerable that he should disparage certificates on the faith of which he himself registers deaths. Medical men are surely entitled to different treatment from registrars.

W. W. is referred to our advertising columns.

THE GLASGOW LOCK HOSPITAL.

To the Editors of THE LANCET.

SIRS,—In your memoranda upon lock hospitals in your last issue you omit to mention that in addition to the Glasgow Lock Hospital for Females there is a ward containing fourteen beds set apart in this infirmary for the treatment of male patients suffering from venereal disease. These patients were formerly treated in the general wards; but, as this was obviously improper, a special ward was provided for them many years ago, under the charge of a male nurse. It is, so far as I know, the only place in the city for the treatment of this disease in males, and it seems to be sufficient, as it is seldom the beds are fully occupied.

I am, Sirs, yours truly,

M. THOMAS, M.D., Supt.

Royal Infirmary, Glasgow, June 27th, 1887.

CASE OF VOMITING PERSISTING FOR THIRTEEN YEARS.

To the Editors of THE LANCET.

SIRS,—I have under my care a case of obstinate vomiting which has been going on for thirteen years. It has been under the care of several physicians, but no benefit has been derived. I have tried all the usual remedies for such cases, but so far without success. Tongue red, papillæ prominent, nose retracted, pinched and haggard expression, bowels constipated. Commences in early morning, subsides towards midday. No history of alcoholism, cancer, or ulcer. I should be much obliged if any of your readers could favour me with any idea as to the line of treatment to be adopted.

I am, Sirs, yours truly,

June 19th, 1887. M.R.C.S. ENG.

"REMOVAL OF BREAST TUMOUR WITH THE AID OF COCAINE."

To the Editors of THE LANCET.

SIRS,—In answer to the note of Mr. Tandy, I beg to state that my sole object in claiming any priority was to elicit further correspondence on the subject, in order to ascertain the extent to which cocaine has so far been pushed, and with what results. As a matter of fact, the operation was performed on April 1st.

I am, Sir, yours faithfully,

Putney, June 24th, 1887. EDW. F. GRÜN.

COMMUNICATIONS not noticed in the present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Goodhart, London; Dr. Lindsay, Belfast; Dr. Savage London; Dr. Steavenson, London; Dr. McCall Anderson, Glasgow; Mr. Da Costa, Kingston, Jamaica; Dr. Thomas, Glasgow; Mr. Hulme, Birmingham; Mr. Marcus Gunn, London; Mr. Mansell Moullin; Mr. White, Wolverhampton; Dr. Macgregor, Wellington; Mr. J. Clinical Lecture
ON
DYSPNŒA, ESPECIALLY ON THE DYSPNŒA OF ASTHMA AND BRONCHITIS, AND THE EFFECTS OF THE NITRITES UPON IT.

Delivered in the Edinburgh Royal Infirmary, December 17th, 1886,

BY THOS. R. FRASER, M.D., F.R.S., F.R.C.P.E.,
PROFESSOR OF MATERIA MEDICA AND CLINICAL MEDICINE IN THE UNIVERSITY OF EDINBURGH.

GENTLEMEN,—In the study of disease in the wards of the infirmary your attention is very frequently drawn to the occurrence of dyspnœa, or difficulty in breathing. You have seen that it presents itself in various forms and degrees, in various conditions of the patient, and in connexion with many diseases. We have together studied several of its forms and varieties. We have seen it associated with disease of the heart, with morbid changes in the larger air passages, with pain in the thorax, and with diseases of the lungs; and it has been our endeavour to distinguish in each case any peculiarities in the phenomena which accompany it. We have seen, for instance, in cardiac disease, that it is associated with evidence of valvular lesions, or of dilatation of the heart, or of disease of the large bloodvessels that it is frequently paroxysmal, the paroxysms being induced by physical exertion or mental excitement, although even in the interval between each exacerbation it does not altogether depart; and that pain in the region of the heart or extending into the shoulders and arms is often one of its superadded miseries. In disease of the larger air passages, such as œdema or spasm of the glottis, constriction of the trachea, or paralysis of the vocal cords, we have several times observed that the great difficulty in respiration seems to occur during inspiration, which is laboured and prolonged, while the expiration is relatively brief and without effort. In thoracic pain of pleuritic or neuralgic origin, the attitude of the patient, and especially the modifications in posture and movement adopted by him, are almost sufficient to characterise the dyspnœa apart from the readily discoverable conditions by which the pain is induced. In asthma, the opportunities for investigating the phenomena have not been altogether favourable, as our cases have presented the peculiarity, which so frequently occurs in this disease, that the dyspnœa has made its appearance only during the night or early morning. Most of you, however, are familiar with the circumstances that in asthma the dyspnœa is characterised by loud wheezing sounds and great prolongation of expiration, that it is paroxysmal in its manifestation, leaving the patient free or nearly so from all symptoms of breathlessness in the intervals, and that no structural alterations have as yet been discovered to account for the intense distress which marks each paroxysm. On the other hand, examples of the dyspnœa of bronchitis have been abundantly presented to you for consideration. You have seen that it is associated sometimes with acute, sometimes with chronic inflammation of the bronchial tubes, that it very frequently occurs in patients suffering from emphysema, that it is often paroxysmal, and that it is accompanied with pain or uneasiness over the front of the chest, with a sputum that may be tenacious or frothy and watery, and with such auscultatory phenomena as rhonchi and sibilations, crepitations, and prolonged expiration.

While the dyspnœa in each of these conditions would supply abundant material for full and elaborate discussion, my intention to-day is to consider with you in further detail some of the phenomena presented by it in bronchitis and asthma only. I make this selection because our attention has been given in a more special manner during the last few weeks to a consideration of the breathlessness of these two diseases. I group them together because the dyspnœa frequently presents in them many points of similarity, and when it does so I believe that a large element in its production is an element operating in both diseases.

It is in pure (or nervous) asthma that dyspnœa assumes the most intense degree possible in disease of the respiratory apparatus. When the paroxysm occurs at night, the patient may go to bed feeling quite well, but is awakened from sleep by a feeling of suffocation. He sits up in bed in various constrained positions, or he is impelled to leave his bed altogether and walk about, resting now and again to recover strength. He struggles violently for breath; inspiration and expiration succeed each other rapidly for a short time; then expiration becomes brief, the chest seems to become rigid in full expiration, violent respiratory efforts are made, with but little change in the volume of the thorax, and the extraordinary muscles of respiration are brought into play with very inadequate results. After this state of distress has lasted for some time, it may be for hours, relief is obtained, and the patient returns to bed and usually soon falls asleep; but on many occasions this sleep may in a short time be again interrupted by a recurrence of the paroxysm. The great difficulty in asthma seems to be to expel air from the chest, and the expiratory muscles are strained to the utmost in the effort to accomplish this. If the condition of the patient during the period of dyspnœa be further examined, several other phenomena of significance are observed. The normal relationship between inspiration and expiration is found to be reversed, and in place of inspiration being longer than expiration, the latter seems sometimes to be two or three times as long as inspiration. The contrast with dyspnœa produced by constriction of the glottis or trachea, where inspiration is greatly lengthened in its duration, is therefore a very pronounced one. The diaphragm, further, is unduly low, the chest is expanded, and the percussion note is markedly resonant; while, on auscultating the chest, not only is confirmation obtained of the great prolongation of expiration, but every variety of dry râle is heard, snoring, creaking, and whistling sounds displacing each other in different parts of the chest.

Now, what is the cause of this intense dyspnœa? No anatomical lesions, as I have stated, have been found that are sufficient to account for it. It was explained by Willis, and subsequently by Cullen, Romberg, Salter, and others, as due to a spasmodic affection of the muscles and nerves of respiration, and especially of the muscles in the bronchi; and this explanation was generally coincided in for more than half a century. It has not, however, been allowed to remain in undisputed possession of the field, for at various times other and opposing explanations have been advanced. For example, Leyden considered that the asthmatic dyspnœa is caused by irritation of the vagus terminations in the bronchi produced by minute sharp-pointed crystals; but this explanation, after all, involves the production of a spasmodic constriction of the bronchi by reflex irritation. Wintrich denied that spasmodic contraction of the bronchi is possible, and maintained that the only explanation consistent with the phenomena is to be found in tonic spasm of the diaphragm, or of the diaphragm aided by the other ordinary muscles of respiration. Traube, Weber, and Sir Andrew Clark have ascribed the paroxysm to sudden congestive swellings of the bronchial mucous membrane, through the agency of vaso-motor nerves, the changes produced being likened by Clark to the swellings of the skin in nettle rash.

These views represent the more important of the contending explanations that have been advanced. It cannot be pretended that any single explanation has yet been established by the evidence that has been produced in its favour, although I think that the explanation which accounts for the essential phenomena of an asthmatic paroxysm by spasmodic contraction of the bronchial muscles is still the most generally accepted one. But while a spasmodic influence has thus been fully recognised in the production of the dyspnœa and of other of the essential phenomena of asthma, the existence of a spasm element in bronchitis has been but partially acknowledged. Indeed, so far as my acquaintance with the literature of this disease is concerned, spasm of the bronchial muscles is by the greater number of writers ignored as a condition that is ever, much less that is frequently, present. Bronchitis, however, resembles asthma in so far, at least, that in a considerable number of cases dyspnœa is frequently an important sym-

Digitized by Google

ptom, and that rhonchi and sibilations are among the most significant of its phenomena. The production of these râles has generally been attributed to stenosis of the bronchial tubes caused by engorgement, or swellings, or puckerings of the lining membrane, or to deposits of adhesive mucus upon this membrane.

It cannot, gentlemen, be too frequently impresseed upon your consideration that the ultimate objects of all our observations, studies, and investigations in pathology and medicine are the relief of suffering and the cure of disease. These objects will be the more certainly accomplished, the more accurate is our knowledge of the conditions that produce the symptoms of the diseases. I am not without hope that an illustration of this almost self-evident proposition may be found in some facts bearing upon the causation of the dyspnœa in asthma and in bronchitis, which I shall now proceed to describe. Let me first remind you that there are several well-recognised homologies in the structure and nerve connexions of the bronchi and of the smaller blood-vessels. They both contain non-striped muscle, and both are innervated by partly independent centres distributed in their walls, and by nerves proceeding to and from centres remote from themselves.

Although the effects of pharmacological agents upon the functions of the muscle and nerves of bloodvessels have been elaborately studied, their effects upon the functions of these structures in the bronchi have been but little investigated. Among the most striking of the results that have been obtained by pharmacology in the study of the influence of agents upon the bloodvessels is the demonstration that various nitrites cause a dilatation of the bloodvessels by an action restricted to the bloodvessels themselves. It was suggested to me by this fact that light might be thrown upon the production of dyspnœa in asthma and bronchitis by examining how far the dyspnœa and some of its associated phenomena could be modified by the action of nitrites. It seemed to be of importance to include in this observation not only the influence upon the dyspnœa (for any influence on it alone might be explained by an action upon nerve structures remote from the bronchi themselves), but also the influence upon the associated phenomena which have their seat of origin, without doubt or ambiguity, in the bronchi themselves. The associated phenomena, to which I attach the greatest importance, are the dry râles, audible in these diseases when the chest is auscultated, and conspicuously present along with the dyspnœa.

The first observation I made with these objects in view was in 1880, on a patient twenty-two years of age, of markedly nervous diathesis, who had suffered from asthma for several weeks. The chest was auscultated during an asthmatic paroxysm of moderate severity, and it was found that cooing, whistling, and creaking râles were abundantly present. She inhaled during fifty seconds a few minims of nitrite of amyl. Two minutes after the inhalation had been commenced the râles had entirely disappeared and her breathing had become quite easy. In another minute the râles had returned and the breathing had become more difficult. After an interval of six minutes, when both the râles and dyspnœa were present in their original abundance and severity, she again inhaled nitrite of amyl, this time for thirty seconds, and in forty-five seconds after commencing the inhalation the râles had entirely disappeared and the breathing was perfectly unembarrassed. In five minutes afterwards, the original state of breathlessness, with its accompanying auscultatory phenomena, had returned. After an interval of ten minutes, nitrite of amyl was a third time inhaled, with essentially the same results as on the previous two occasions.

This observation showed in a very striking manner that nitrite of amyl very rapidly caused every sensation of dyspnœa to disappear. The coincident effects of the highest interest were that so long as the dyspnœa was removed, and only so long, were the cooing, whistling, and creaking sounds silenced, and so long also were there present those well-known modifications in the pulse characteristics which indicate dilatation of bloodvessels. Since this observation was made I have accumulated much evidence of a similar kind. In a few other cases nitrite of ethyl as well as nitrite of amyl were given by inhalation, but in the greatest number of the observations the administration was effected by the introduction of the nitrite into the stomach, and thus a much more prolonged action was obtained. In this manner, not only has the influence of nitrite of amyl and of ethyl been examined, but also that of nitrite of sodium and of the nitrite-acting substance, nitro-glycerine. Further, in several cases of severe asthmatic orthopnœa occurring during the night, remarkable alleviation, with coincident silencing of the râles previously abundant in the chest, were obtained in several observations made for me by Dr. Vaughan and Mr. Toft on patients in the wards.

In bronchitis accompanied with dyspnœa similar effects were also obtained. The dyspnœa was removed, and at the same time the previously existing dry râles disappeared. Let me illustrate this action of nitrites in two patients suffering from bronchitis, now placed before you. One of the patients has been in the wards for several weeks, and from previous experience I can confidently predict the changes that will occur. He has suffered at intervals during the last fifteen years from bronchitis, the lungs are emphysematous, and his chief complaints at present are breathlessness and cough with a rather adhesive and slightly frothy sputum of small quantity. The other patient was admitted into the hospital only yesterday, but I shall be much disappointed if the observation I shall immediately invite you to make on her should fail as an illustration. Her cough originated four months ago from a severe wetting. You observe that she has very obvious dyspnœa, and the sputum which I show you is large in amount, watery, and contains much froth. Both patients are suffering at the present moment from dyspnœa, and, as you have heard from the four members of the class who are examining the patients, two of whom are continuously auscultating the chest of each patient, there are now associated with the dyspnœa an abundance of snoring, whistling, and cooing râles. I now ask Dr. Jeffcoat, the resident physician, to give to one patient four minims of nitrite of amyl in a little water, and to the other two minims of a 1 per cent. solution of nitro-glycerine also mixed with a little water; and the gentlemen who are auscultating will at once inform us of any change in the sounds which they hear, while I have asked the patients to announce the first change which they experience in their sensations. It is only a very few minutes since the medicines have been given, and already you have heard, almost simultaneously, that silence prevails in the chests where before there was a continuous succession of sounds, and that both patients find that they no longer experience any dyspnœa.

The significance of the facts I have now brought before you in connexion with the influence of nitrites upon the dyspnœa of asthma and bronchitis, some of which you have yourselves assisted in observing, is almost self-apparent. They appear to throw light upon the production of the dyspnœa of asthma, and in doing so to confirm the conclusion otherwise arrived at by Biermer that the dyspnœa cannot find its chief explanation in spasm of the diaphragm. They appear also to show that this dyspnœa does not depend on suddenly produced and vanishing constrictions of the bronchial tubes, caused by swellings of a hyperæmic, herpetic, or urticaria-like character; for the means that have been successfully employed to control and terminate the dyspnœa are the very means which should, according to the theory which involves constrictions of this kind, be the most efficient for increasing and prolonging it. Relief of the dyspnœa and removal of the accompanying râles were simultaneously or nearly simultaneously produced by nitrites, whose action is to increase hyperæmia by dilating bloodvessels. As nitrites, however, lessen the contraction of non-striped muscle, it appears to follow that the râles which accompany the dyspnœa of asthma are produced by spasmodic contractions of the bronchial muscles, that the dyspnœa is mainly the result of spasmodic constrictions of the bronchial tubes, and that therefore the old doctrine which attributes the asthmatic paroxysm to spasm of the bronchi is in all probability the correct doctrine. In reference to their bearing upon the dyspnœa of bronchitis we have these facts to assist us: that whenever rhonchi and sibilations accompanying dyspnœa were removed by nitrites, the dyspnœa was also removed or lessened; but when the rhonchi or sibilations were unaffected the dyspnœa was not appreciably lessened. It could not be expected that in all cases of bronchitis the administration of nitrites would be followed by complete relief of the dyspnœa and complete removal of the auscultatory phenomena. In this disease dyspnœa is sometimes produced by mucus or other inflammatory products accumulated in the bronchial tubes, and rhonchi are sometimes heard which are caused by a viscous condition of these accumulated products, and even by accumulations of a similar kind in the

Digitized by Google

threat. In such cases nitrites fail to give complete relief, and they fail to silence the abnormal sounds. That they should fail is a confirmation rather than a refutation of the opinion which I wish emphatically to state—that stenosis of the bronchi due to spasmodic contraction of the bronchial muscles is a frequent cause of the dyspnœa of ordinary bronchitis.

I have not obtained any facts that would justify the preference of any one of the nitrites because it possesses therapeutic advantages over the others in the treatment of asthma or bronchitis. There are, however, conveniences of administration which lead me to give a preference to nitrite of sodium and to nitro-glycerine. They are both extremely stable, and they can readily be given in solution, either by the stomach or by subcutaneous injection. These advantages are not possessed by nitrite of amyl and nitrite of ethyl, and even the latter substance in the alcoholic solution of the *spiritus ætheris nitrosi* of the Pharmacopœia is notoriously a very uncertain preparation. It is probable that the favour with which this preparation is, notwithstanding, regarded, is due not only to the action on the circulation which it shares with the other nitrites, but also to its previously unrecognised influence on dyspnœa, which is no doubt exerted when it is administered, as it so frequently is, in the treatment of bronchial catarrh. When the volatile nitrites are given by inhalation the effects are only of brief duration, but when they are given by the stomach the effects are similar in their relatively prolonged duration to those of the non-volatile nitrites. Nitrite of amyl, nitrite of ethyl, nitrite of sodium, and nitro-glycerine have each proved successful in my observations in relieving the dyspnœa of asthma and bronchitis. I believe they do so, gentlemen, by removing bronchial spasm, and the remarkable power which they possess in doing this will probably lead to their being more largely used than they hitherto have been in the treatment of disease. Where their administration is successful in removing the auscultatory evidences of such spasm, it is difficult to imagine anything more convincing of the beneficial influence that can be exerted upon the conditions of disease by pharmacological agents. The observer has presented to him a patient in whose thorax a continuous succession of varying sounds is heard. Within a few minutes after a nitrite has been administered, the endless succession of noisy breath accompaniments gives place to an almost complete silence, in which only the subdued quiet of normal respiration is heard, and at the same time, what to us is of even greater interest and importance, the distress of dyspnœa, or, it may be, the intense suffering and anxiety of orthopnœa, is entirely removed.

Lectures
ON
INJURIES OF NERVES.

Delivered at the Royal College of Surgeons,

BY ANTHONY A. BOWLBY, F.R.C.S. ENG.,

DEMONSTRATOR AND DEMONSTRATOR OF SURGICAL PATHOLOGY AT ST. BARTHOLOMEW'S HOSPITAL, HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS.

LECTURE III.—*(Continued.)*

TREATMENT OF NERVE INJURIES.

The proper and rational treatment of nerve injuries is essential is an accurate knowledge of their pathology. It is due to the want of this knowledge that the erroneous views as to nerve union and of the treatment requisite for success have to be attributed. To the opinions held on these points I shall now briefly refer, for they seem to me to

[illegible] of Galen "that nature was powerless to repair" held unlimited sway until the time of Haighton, and the experiments of these [illegible] the Philosophical Society's Transactions completely subverted the doctrines taught [illegible] surgeons experimented on dogs by [illegible] nerve on the one side only, and having kept the animals alive for a varying number of days, they demonstrated that division of the opposite nerve trunk was not sufficient to cause death, previous experiment having shown that a simultaneous section of both vagi was inevitably fatal. They therefore concluded that the one nerve must have been reunited before the second operation was performed. Swan, Fontana, Descot, and Prévost arrived at the same conclusions, and the result was a very general belief that nerves when divided were *inevitably regenerated*—a belief which led to a corresponding carelessness in the treatment of such injuries, and which has been widely prevalent up till the most recent times, not only in England, but also in France and Germany, where Flourens and Steinrueck upheld the theories started in this country. The investigations of Waller, Vulpian, and Philippeaux about the year 1852, brought a new light to bear on this subject, and formed the first step in the accurate pathology of nerve lesions. It was shown by these physiologists that the peripheral end of a divided nerve underwent degeneration, and that some months intervened before the nervous substance was repaired.

Theoretically, then, a corresponding time should always intervene before the nervous functions were re-established, and thus, though the theory of inevitable nerve regeneration was not relinquished, it was assumed that union never could take place by first intention. But the eyes of surgeons could no longer be shut to the cases which constantly came under their notice, and as experimental inquiry yielded to clinical observation, the fact was speedily established that in a large number of patients suffering from nerve lesions no union of any kind occurred. In this branch of pathology, however, as in many others, the discretion of pathologists speedily outran their wisdom, and the theory of "supplementary sensibility" and "supplementary motility" was, especially by French surgeons and physiologists, adopted to the exclusion of nerve regeneration, and more especially to that of reunion by first intention. In a former lecture I have discussed the probabilities and proofs in favour of union by this latter method, and also the evidence bearing upon the presence and amount of nerve anastomoses and supplementary sensation; I shall therefore take for granted that the possibility of immediate union is an established fact, and shall now pass on to consider the best means at our disposal for procuring the same.

Suture of nerves.—In order that any tissues which may have been divided by the surgeon or else by accident should unite as speedily as possible, it is plainly of the first importance that they shall be closely approximated. How should this approximation be maintained in the case of divided nerves? To this question there can be, in my opinion, but one answer —"By suture"; and the reason that this answer has not been given very many years ago is to be found in the erroneous views as to the probable results—e.g., tetanus, &c.—of the irritation which the stitches might set up, as well as in the mistaken ideas of nerve repair just alluded to. Putting aside the more than doubtful assertion that nerve suture was performed in the middle ages by Lanfranc, Guy de Chauliac, &c., the operation is said to have been performed by Arnemann in 1826 and by Flourens in 1828. At a later date it was practised in several instances by Dupuytren at the Hôtel Dieu. But although these cases are interesting from a historical point of view, the time when nerve suture came to be practised in surgery on a definite physiological basis is much more recent, and may be said to date from 1864, when Laugier, a French surgeon, sutured the ends of a recently divided median nerve. Laugier claimed that immediate union resulted, but whether this was or was not the case is not sufficiently clear. In 1865 MM. Eulenberg and Landois made numerous experiments on animals, and concluded that after suture not only does the peripheral end of the divided nerve degenerate in a manner precisely similar to that noticed when no sutures are used, but that the sutures themselves are absolutely harmful, producing neuritis and perineuritis, and may even give rise to suppuration and secondary abscesses in the lungs. These statements, combined with the ever-present dread of tetanus, naturally dissuaded surgeons from universally adopting such measures, and in 1868 Boeckel of Strasburg related a case in which, after division of the median at the wrist, there was a recurrence of sensation in two months, except in the index finger; no sutures had been used, and the author rather illogically concluded that they were never necessary. Some years later Le Dentu noted that bullæ occurred on the fingers after an attempt

Digitized by Google

had been made to procure immediate union by suture of a recently divided median; this lesion he attributed to the irritation caused by the sutures, and not to the cutting off of the nervous influence. There can be but little doubt that this conclusion was an erroneous one, for as I have already endeavoured to prove, these trophic lesions are not of an irritative nature, and the bullæ were no doubt due to a failure of union by first intention, and not to the presence of the catgut. But the results obtained by Eulenberg and Landois are entirely different to those of other experimenters, some of whom in vain attempted to induce neuritis by means of setons and other irritants, and, what is of much more importance, amongst a large number of cases in which sutures were applied to human nerves these much-dreaded consequences were conspicuous by their absence. The result of further experience has thus come to be that, as far as any danger is concerned, no surgeon would hesitate to use the most obvious means of approximating the ends of a divided nerve, and would fearlessly insert as many stitches as might be necessary without any dread. But, putting the danger out of the question, is the patient any more likely to have the continuity of his nerve restored if the ends are sutured than if they are left to nature? To this I would answer most unhesitatingly in the affirmative, for, judging by accounts published by various authors and by my own observations, I can have no doubt but that in the vast majority of untreated nerve wounds either no union at all or but a most imperfect one can be expected. That the ends are sometimes united even if left to themselves is proved by some of the cases already narrated, but under these circumstances a primary union can but rarely occur, for the ends are but seldom in apposition, a state which is absolutely necessary for this method of healing. And again, in cases where primary union fails, by the time when degeneration and regeneration have occurred in the distal fragment, it very frequently happens that in the process of cicatrisation the nerve ends have either become adherent to the surrounding muscles and tendons, or else are widely separated by fibrous tissue, which forms an impenetrable obstacle to further attempts at reunion. These latter conditions, at any rate, can be obviated by the employment of sutures, and, even if union by first intention fails, the nerve is left in a much more favourable condition for subsequent regeneration than is otherwise the case. Now, the experiments by Glück proved very clearly that in fowls, rabbits, &c., the use of sutures was followed by a primary union of the divided nerve, and on these grounds an analogous result in man might fairly be expected. The records, however, of cases in which such treatment has been adopted supplies information of a much more valuable nature, and it is to the evidence afforded by such cases that I would rather direct attention.

Primary nerve sutures.—The operations which may be undertaken for the suture of divided nerves are conveniently divided into two classes: 1st, primary; 2nd, secondary. The operation of "primary suture" consists in stitching together the ends of a divided nerve either immediately after injury, or else very shortly afterwards—before, in fact, the process of healing of the wound has commenced. This operation should, in my opinion, be performed in every case of nerve injury in which it is possible. There are, of course, cases in which such an extent of nerve has been removed that it becomes a physical impossibility to bring the severed ends into apposition, and in such alone should the operation be omitted. I have no doubt that the operation of nerve suture is absolutely harmless, and that when the nerve ends are left unsutured union is most unlikely to occur at all, and at best is very imperfect. Lastly, that when the nerve ends are carefully sutured and maintained in apposition, a restoration of function is the most frequent result. Under this belief, I cannot agree with those surgeons who consider that in cases of clean-cut wounds sutures should not be inserted. I believe these are just the cases best suited for suture. M. Nicaise, in his article on Injuries of Nerves in the "International Encyclopædia of Surgery" says: "When the section is clean cut and simple, without extensive wound of the integument, then suture should not be resorted to unless the separation is considerable," and other surgeons, especially on the Continent, express the same opinion. I am perfectly convinced that such advice should not be followed. No possible harm can result from suture, and the prognosis of the case of a wounded nerve left to itself is most unsatisfactory.

The mode of application of the suture is a matter which has received much more attention than it really deserves. For a long time it was taught that the sutures should only be passed through the nerve sheath, and that it was dangerous to pass the needle through the bundles of nerve tubes themselves. This, again, was all due to theory, and gradually surgeons have learnt that the thought of danger is one with which they need not trouble themselves when considering the best method of fixing the separated nerve ends in apposition. I have myself passed sutures completely through human nerves, and have frequently seen them passed by others without the slightest evil result, and in the now numerous cases recorded in surgical literature the same treatment has been followed without a single recorded instance of any complication. The method which I would recommend is the following: A small needle armed with the suture should be passed completely through the nerve trunk at right angles to its long axis, about a quarter of an inch from the cut surface in each end, and in large trunks another suture may be passed at right angles to the first. These sutures should then be drawn tight until the opposing cut surfaces are brought into contact, and finally the edges of the sheath should be neatly stitched by three or four more sutures passed through it, so as to include within it all the cut tubules.

The material for suture.—The choice of a material for suture is naturally influenced by the same considerations as those which obtain in the similar operation of ligature of vessels, and just as in the latter it is advisable to use a tissue which will not act as an irritant and will be absorbed, so is a similar material indicated in the suture of nerves. In the majority of recorded cases catgut has been used, and I am inclined to consider that for small nerves carbolised catgut is the best material. In those cases, however, in which there is any unusual tension, or in which it is anticipated that, on account of any complication, it may be necessary to disturb the wound, I think that carbolised gut does not possess the proper amount of resisting power, and does not last a sufficient length of time. In such cases I should use by preference a more stable ligature, such as chromicised catgut, kangaroo tendon split into sufficiently small filaments, horsehair, or fine silk; I prefer the two former to the latter. After apposition has been obtained by suture, the limb should be fixed on a splint in such a position as to keep the injured nerve in a state of the least possible tension. The wound should be thoroughly cleansed, all sutures used should be first rendered aseptic, and every endeavour should be made to ensure healing by first intention.

The value of primary suture of nerves.—Clinical facts must furnish the basis on which an opinion may be formed as to the value of primary nerve suture. It is useless to argue from any other than a clinical standpoint. The investigations of experimenters on animals of various kinds possess a value of their own, but the conclusions arrived at in this way cannot possibly be directly applied to man. When we consider that after the section of the spinal cord of a pigeon there may be a complete restoration of continuity, when we are told that in a monkey three or four inches of nerve may be remade in as many months, the absurdity of applying to man the conclusions arrived at by experiment is very obvious. The cases of primary suture which have been observed by myself at St. Bartholomew's Hospital may be summarised as follows:—The median nerve was sutured on eight occasions, each time with success. The ulnar nerve was sutured eight times, of these, two cases were completely successful, two were partially successful, and three were failures. In one case primary suture failed, and a secondary suture seven months later was followed by complete success. The median and ulnar nerves were sutured at the same time in one patient, with success. The total number of cases observed by myself thus stands at seventeen. Of these, twelve were successful, two were partially successful, and three were failures. In two of these cases union by first intention without previous degeneration ensued. In each case the median nerve had been divided. In other cases some fibres appeared to unite by first intention, although the bulk of the nerve did not do so.

Cases already recorded.—I have found much difficulty in summarising the cases reported in medical literature, for in many the reports are too meagre, in others they are evidently inaccurate, and in some they are imperfect in important particulars. I have thus been compelled to classify a certain number as "doubtful successes," for although they are

Digitized by Google

claimed as successful by their authors, it is not possible to accept them without doubt in the absence of important details. It is, of course, probable that in the majority of these patients there was perfect recovery; but I have thought it more satisfactory to include in the "successful" class only those about which there could be no doubt at all. The following list, I believe, includes practically all the cases recorded as late as the end of the year 1885:—

Of primary suture of the median nerve, six cases were "successful," six were "doubtful successes," five were partially successful, two were failures, and in one case the result was not stated—total, twenty. Of primary suture of the ulnar nerve, four cases were successful, four were doubtful successes, three were partially successful, and four were failures—total fifteen. Of primary suture of the musculo-spiral nerve, four cases were successful. Of primary suture of the radial nerve, one case was successful. Of primary suture of the median and ulnar nerves simultaneously, two cases were successful, two were "doubtfully successful," four were partially successful, and three were failures—total eleven. Of primary suture of the sciatic nerve, one case was partially successful. Of primary suture of the peroneal nerve, one case was a failure. Of primary suture of the post-tibial nerve, one case was partially successful. Total number of cases of primary nerve suture recorded up to December, 1885, fifty-four—viz., successful, seventeen; doubtfully successful, twelve; partially successful, fourteen; failures, ten; result not stated, one. These added to my own seventeen gives a grand total of seventy-one—viz., successful, twenty-nine; doubtfully successful, twelve; partially successful, sixteen; failures, thirteen; result not stated in one.

Now, at first sight it might seem as though such a summary as the above would give a very fair insight into the prognosis of cases of primary nerve suture. Yet I venture to say that in some respects it is unavoidably misleading. I well remember that when, some few years ago, I first interested myself in the question of nerve suture, I was inclined to form a somewhat low estimate of its value. I saw cases operated upon, and I saw them frequently leave the hospital without any material sign of nerve union, and with deformities resulting from trophic lesions, from contracted and atrophied muscles, or from ankylosed and painful joints. I was told that most of the cases operated upon were failures, and such indeed was my first impression. Further investigations, however, soon placed matters in a different light. I found that in almost all of the hitherto recorded cases nothing was noted of the state of the paralysed parts after a few weeks or months at the latest, and I therefore determined to keep my patients in sight, not for months, but for years. And whilst thus engaged in watching those who had been more recently operated upon, I also sought out other patients who had met with nerve injuries in past years. On examining many of the latter, I found that, as might be expected, most of those whose nerves had not been sutured at the time of injury were but little improved, Others had gradually recovered. In some of the latter the nerve ends had been sutured; in some this had not been done. But what most interested me was to find that in many patients who had subsequently completely recovered there had been a long interval of many months, or even of years, between the time of injury and the return of sensation or motion, and I saw at once that no case should be written down as a failure simply because the operation of suture was not followed by immediate success. It was with this impression that I continued to watch the various cases that I met with, and I believe that there is no other class of surgical injuries which so well repay clinical observation. So little has been written of them that they are constantly supplying surprises. Each case has its own peculiarities, each runs its own course, yet there are certain general rules which apply to all, and enable the surgeon to speak with tolerable confidence as to the final results of cases of nerve injury which have been treated by primary suture. If there is one fact more than another which stands out in the clinical histories of the patients who have been under my own observation, it is that after the failure of union by first intention, after trophic changes of many kinds, after complete atrophy and degeneration of the [illegible] recovery may yet be complete.

[illegible] regulate in these cases. The surgeon [illegible] have patience, and if the nerve ends have been properly and maintained in accurate apposition, it is to time that the final result must be left. Putting aside for the present the cases in which primary union occurs, I would refer to the period that elapsed in the various patients treated at St. Bartholomew's Hospital between the time of suture and of repair.

Of the six cases of successful suture of the median nerve, five months elapsed in the first case before any signs of union were apparent; in the second case restoration of function occurred within a few months; in the third case it occupied more than a year; in the fourth case about a year; in the fifth case about six months; in the sixth case there was no improvement for more than a year, and final restoration of function was not complete for one year more.

Of the two cases of successful union of the ulnar nerve, in the first at the end of a year the hand was clawed, the muscles atrophied, and the skin anæsthetic; it was not until three years later that restoration of function was complete and perfect. In the second case it was thought, after several weeks' waiting, that the ends of the sutured nerve had become separated, and they were exposed only to show an apparent union. The patient was discharged as a case of "failure," yet subsequently, many months later, function was restored.

In the case of successful suture of the median and ulnar nerves, the muscles wasted, the hand was paralysed, cold, and blue, and the skin was anæsthetic six months after the operation. In another year the hand was practically restored to its natural condition.

The facts are plain. When a nerve has failed to unite by first intention its lower end degenerates, and, again, regenerates in the way I have already described. That such regeneration is hastened by contact with the proximal end I have no doubt, but in the cases in which the muscles have atrophied and degenerated, it is evident that some time must elapse before they can be re-made. Motor functions, as a rule, take longer to return than do sensory ones.

Now, if it be conceded that years may elapse before return of function, it is evident that where the suture has only been performed a few weeks or months, hasty conclusions as to the final result should not be drawn. Keeping this in mind, let us turn to the other cases that I have detailed and placed under the heads of "partial success" and "failure." Of two cases of "partial success" after suture of the ulnar, one has only been performed three months, the other six. In each there was, when I last saw the patients, a considerable return of function, and I feel sure that each will further improve. Of the three cases of "failure," in one the wound sloughed considerably. In the other two, after lengthened intervals no union occurred. To these I shall again refer in discussing the "causes of failure," and would now turn to the cases of primary suture described by other authors, and already tabulated.

Without stopping to consider the cases recorded as "successes," let us briefly glance at the length of time the others—those of "doubtful success," of "partial success," and of "failure"—were kept under notice. Of the cases of median suture six, in which success was doubtful, were under notice respectively for two months, twenty-five days, two months, one month, a few days, and a few weeks. In five cases of "partial success" the times were eight months, a few weeks, several months, no time stated, and one month. In the two cases of failure no time is mentioned; the patients do not seem to have been under observation more than a few weeks at the outside. Looking at the cases of suture of the ulnar nerve, we find that of four cases of "doubtful success" the patients were seen for periods of six weeks, eighteen days, no time specified, and five weeks. Of three cases in which there was partial success, for two years, "some months," and one month. Of four cases of "failure" the patients were observed for three weeks, three weeks, one year and a half, and three weeks. Of cases of suture of the median and ulnar nerves, in two, in which success appears doubtful, the patients were under observation for "some weeks" and a year and a half respectively. Of four cases of "partial success," for ten weeks, three weeks, fourteen days, and three months. Of three cases of "failure," the patients were seen after six weeks, two days, and eight days respectively. In the case of the sciatic nerve the only patient was under notice for thirteen days, and there was then some improvement. The only patient on whom a primary suture of the peroneal was performed died sixty-five days later with gangrene of the thigh; the nerve ends were found separated. In a case of primary suture of the posterior tibial nerve, there was a partial restoration of function in four weeks.

A consideration of these facts leads to the inevitable conclusion that the reports of these cases cannot be considered final. In the enormous majority of cases of failure or of partial success the time that had elapsed since operation was far too scanty to allow of reunion, supposing that union by first intention had failed. I am convinced that it would be a most grave error of judgment to conclude, because no restoration of function had occurred even as late as a year or more, that such was not possible. The cases observed by myself supply abundant proof of the correctness of this assertion.

Prognosis of primary nerve suture.—In considering the prognosis of cases of primary nerve suture, there are two chief questions to answer. First, what is the probability of restoration of function? Secondly, how long will it take for function to be restored?

With regard to the first question my own mind is clear. *The probability is that function will be restored.* I am quite convinced that if the nerve ends have been carefully coapted and kept in position, restoration of function will ensue in the great majority of cases. The instances I have given are my authority for this statement, for I have shown that in by far the greater number of failures, or of partial successes, the time which had elapsed when the cases were published was too short to permit of accurate conclusions being drawn. But, whilst I would thus give a good prognosis, I would at the same time warn the patient that some trifling inconveniences may remain permanently. Thus, in cases otherwise successful, I have noticed complaints of slight stiffness of the muscles or joints, of pain or aching when the weather changed, or when the parts were cold or wet. Other patients have complained that, though they had good tactile sense, nevertheless the parts felt, in a way that they could not explain, different from what they did before the accident, and it was evident that much of the delicacy of the sense of touch was permanently impaired.

The earliest signs of returning function are usually met with in relation to the sense of touch. The first thing the patient notices is that he can feel in a part previously anæsthetic. Just at first he does not localise properly—perhaps refers sensations from one finger to the other, or from a finger to the palm of the hand. And indeed this is only what might be expected if we consider that the several divided nerve fibres can seldom be united as before the injury, that the proximal end of a fibre which was distributed to the middle finger may become united to the peripheral end of one distributed to the thumb, and so forth. The patient has, in fact, again to educate his sense of touch in the way that all infants have to do. What has generally surprised me is the rapidity with which this education is completed, rather than the difficulties which at first present themselves. The return of the sense of touch, followed by that of pain and of temperature, affords further ground for promising return of muscular power. Will the atrophied and shrunken muscles regenerate (I am supposing some time has elapsed without improvement)? They will. Their power will return; their bulk will increase. Trophic lesions also will disappear, and the tissues will practically return to their normal state. Do any general conditions influence the prognosis? I think they do. I am of the opinion that prognosis is better in the young than in the old; best of all in children and young adults. I think I have observed that regeneration is more rapid in warm summer weather than in the winter time, when paralysed parts are liable to become cold and livid, with impeded circulation and lowered vitality.

The consideration of these points leads directly to the second question in the prognosis: How long will it take for function to be restored? This is not a question that can be answered directly. The first point for consideration is, What is the probability of union by first intention? For an answer to this I would turn to the cases already tabulated. In only two instances out of the seventeen under my own observation has union by first intention resulted. In each the divided nerve was the median. In three cases of suture of the ulnar nerve recorded by other authors,—namely, Boeghold, Bramwell, and Clark,—supposing the accounts to be accurate, there was union by first intention. In one case by Kraussold of suture of the radial, median, and ulnar there was a similar result. Thus, out of a total of seventy-one, there are but six cases of union by first intention, and of some of these I am bound to confess I have some doubt, for there are absolutely no details supplied of those by Bramwell and Clark, and but few by Kraussold. I should therefore conclude that union *by first intention* is not to be *expected* in any given case. And, supposing that such union does not occur, what time must elapse before recovery? This is a question quite impossible to answer. It may be weeks, months, or years; no one can tell. Recovery may be preceded by trophic changes, joint disease, and paralysis, or none of these may be present. But with regard to time I could not say more than that considerable improvement will probably occur within a year, and of this I would feel more certain in a young than in an old person, and where the wound has healed readily without much suppuration. I would give up no case as hopeless until the lapse of at least two or three years, and not then if any improvement was in progress.

Does the prognosis differ in the case of different nerves? This is a question I have often asked myself. I think it does. All the cases of suture of the musculo-spiral have been successful, and, although it is looking ahead a little, I would remark that a similar success has attended almost all the operations of secondary suture in the case of this nerve. I should therefore be the more inclined to give a favourable prognosis. Concerning the median nerve, I find that all eight cases seen by myself have been successful; while of twenty recorded by other authors only two are recorded as failures, and these may be explained by the short length of time they were kept under observation. With regard to the ulnar nerve, my impression is that motion never returns before sensation, and that of all paralysed muscles the interossei are the ones which are most slow to recover. I have not seen a sufficient number of injuries of other nerves to form any opinion as to their relative capabilities of repair, and, indeed, what I have just said in respect of the nerves of the upper extremity rather embodies my own somewhat vague impressions than forms any definite conclusions.

ON RELIEVING TYMPANITES BY PUNCTURE OF THE ABDOMEN.

BY JOHN W. OGLE, M.D. OXON., F.R.C.P.,
CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL.

THE inconvenience of even moderate flatulent distension of the stomach and bowels, of which most people have personal experience, is so great that it may be easily understood, upon reflection, how highly distressing and painful, and indeed how fatal, excessive and unrelieved distension of the same viscera may prove (whatever the cause). For what is the point, the signification, of unwonted and protracted gastro-intestinal inflation? It means, of course, interference with the contraction, and, therefore the descent, of the diaphragm, the "great inspiratory muscle"[1]—i.e., interference with the movements of the lungs, and with the action of the heart which rest upon the diaphragm; and, no doubt, serious damage, by pressure on the various nerves, eminently the sympathetic system, and upon the bloodvessels as well in the abdominal[2] as the thoracic cavity.[3] The likelihood of unwonted pressure on the sympathetic system by over-distended stomach and bowels, and the consequent evils, will be apparent when one considers the relation of those viscera to the grand solar plexus and the various ganglia which exercise such important influence upon the circulation and upon the numerous secreting organs whose action, reflexly, on the heart is so conspicuous. This excessive gastro-intestinal distension has the significance of that paralysis, more or less complete, of the diaphragm which arises from lesion of the phrenic nerves, division of which,

[1] That chief or special agent by which the cage of the thorax is vertically increased, and by which also the transverse diameter of the lower part of the chest is found to be enlarged. The diaphragm was designated by the great Haller as a muscle "post cor, facile princeps."

[2] The movements of the diaphragm having great physiological influence on the functions of the abdominal organs.

[3] Interference with the contraction of the diaphragm is, probably, more disastrous in the man than in the woman, as in the former the thorax is ascertained to be dilated mainly by the descent of the diaphragm, whilst in the latter it is brought about considerably by raising of the sternum and the ribs. This difference has been attributed to the greater flexibility of the ribs of the woman, permitting their greater movement by the muscles.

Digitized by Google

as we know, ere long produces death.[4] And, of course, interference with the inspiratory descending movement of the diaphragm, limiting the due and proper expansion of the chest cavity, quickly limits the exchange of the respiratory gases in the blood.

In a communication to the Transactions of the Provincial Medical and Surgical Association (vol. xii., 1844), my friend, Dr. Sibson, with whom, later on, I often worked, described the "changes in the situation and structure of internal organs" under various circumstances. After noticing the "terrible anxiety," "dyspnœa, and interruption of circulation" existing in cases wherein the circulating and breathing apparatus are thrust up by the diaphragm in many diseases of the abdomen, he remarks that the deadly symptoms are not due so much to the disease within the abdomen as to the clogging of the heart and lungs. One of the most graphic descriptions of the symptoms produced by extreme tympanites is given by a French writer (Mothe), to whom I shall allude later on. After enumerating the distressing eructations, the loud noises of the flatulence, and the pain following their cessation, the vomiting, the heat, the quick and strong pulse, this writer describes the laboured respiration, the impossibility of taking food, and the constipation, and he proceeds: "Successivement viennent les anxiétés, l'accablement, les défaillances, les extrémités froides," &c. Well may the symptoms connected with obstruction or occlusion of the bowels warrant the designation of "miserere mei," which it has obtained. Ambrose Paré declares that rupture of the bowel may be the result of over-distension by flatulence, and Dr. Church tells me he has seen the same resulting phenomena, most likely from there being ulceration of the inner surface. He observes: "There are few points in the practice of medicine of more importance than this—to remove or prevent flatulent distension of the abdomen." In 1848[5] Dr. Sibson pointed out that a highly distended stomach also pushes up the liver, which is so compressed between the stomach and diaphragm that "an additional amount of blood from the hepatic vena cava is directly thrown into the right cavities of the heart at the very time that the heart's action is embarrassed by the upward pressure of the stomach." The extent to which the diaphragm may be pushed upwards by abdominal distention is well illustrated by a diagram, which shows the upper convex boundary of the muscle to be behind the third intercostal space on the right side, and behind the fourth one on the left side. Dr. Sibson observes that when gastro-intestinal distension accompanies acute disease, such as peritonitis, it is often the immediate cause of death.[6] In 1873 that physician gave a clinical lecture at St. Mary's Hospital[7] on the "Influence of Distension of the Abdomen on the Functions of the Heart and Lungs."

Quite recently attention has been drawn, in THE LANCET,[8] to the subject of relief of such flatulent distension as I have mentioned, in puerperal cases, by means of puncturing the abdomen; but this method of procedure has been adopted in many instances of tympanites in connexion with other forms of disease than child-bed fever, with which both the physician and the surgeon have to do, and it is to their performances in [illegible] that I venture at this time to draw especial attention. The subject was mooted in the year 1871 in several communications to the *British Medical Journal*, soon after which I saw at least two cases in which death was apparently the direct result of unrelieved excessive tympanites (no other serious affection being discovered after death; [illegible], in fact, of "mors sine morbo"), which determined me not to lose any opportunity of suggesting relief in such cases, after all other means had been tried, by the simple and readily performed operation of puncturing the abdomen.[9] Somewhat later such an occasion presented itself in the case of a lady suffering from a tumour (eventually removed successfully) which, by pressure on the bowel, apparently, had produced such an amount of tympanites that the descent of the diaphragm was so incapacitated that life was seriously threatened. In the middle of the night intense dyspnœa, failure of circulation, and extreme prostration came on, when it seemed impossible "decantare loca dolentia," and nothing remained to be done but to give alleviation, if it might be, by puncturing the abdomen. Accordingly, Sir J. Paget was called in, who assented to the suggestion, and, by means of a fine trocar, punctured the prominent transverse colon in two or three places. This gave prompt and decided relief.[10] A large measure of very fetid gas was rapidly evacuated, continuing to rush out with a loud hissing noise for the space of some seconds.[11] The swelling of the abdomen at once subsided to a very considerable extent, thus averting at once collapse and destruction; in the ease procured to the patient, reminding me forcibly of the absolute and almost instantaneous repose, and not infrequently sound sleep, which follow the operation of tracheotomy in cases of croup or diphtheria. This personal experience aroused in my mind so great an interest in this operative procedure, that I resolved to make some excursions into our medical literature, and to ascertain what had been recommended or achieved in connexion with the matter—one, it must be allowed, of great practical importance.

I here propose to offer some fruits of my inquiries, and to set forth a "catena" of the main illustrations of the subject which I have encountered.

As no investigation into the history of any point of medical interest would be complete without reference to Sprengel's "Histoire de la Médecine," I find it there stated[12] that in 1617 P. Pigra, and, somewhat later, Ambrose Paré, recommended, in cases of strangulated herniæ, the process of pricking the intestine with a needle for the purpose of assisting the reduction. Later on, Corneille, Soolingen, P. Dionis, and Heister, at the beginning of the eighteenth century, did the same. It is possible, as Dr. Saunders (to whom I shall allude later on) suggests, that puncture for relief of tympanites may have been suggested originally by the necessity which the older surgeons felt themselves under, of puncturing strangulated bowels, which they did with round or triangular needles.

Commencing now with some of the older medical writers

[illegible] and Bowman's Cyclopædia of Anatomy and Physiology it is [illegible] (vol. ii., p. 5) that "if the phrenic nerves be divided in a living [illegible] great difficulty of breathing follows, the entire labour of respiration [illegible] thrown on the muscles which elevate the ribs. If the spinal [illegible] be divided above the giving off of the phrenic nerve, respiration [illegible] but not so if divided immediately below that point; and [illegible] Beclard could find no cause but a tumour of [illegible] nerves. I may say, in passing, that in the St. George's [illegible] Museum we have a specimen showing a phrenic [illegible] were, into two by the enlargement of a bronchial gland, [illegible] connected with an irregular dense mass containing much [illegible] matter." At the lower part of the specimen [illegible] of the nerve take their course through an enlarged [illegible] gland. The specimen was found in the dissecting-[illegible] Medical Gazette, vol. vii., 1848, p. 169.

[illegible] how to distinguish whether the stomach alone is dis-[illegible]

[illegible] Medical Journal, Aug. 2nd, 1873.

[illegible] the number for April 9th, 1887; by [illegible], April 23rd; and by Dr. Nesfield, [illegible]

[9] And the remembrance of my duties as curator of the Pathological Museum at St. George's Hospital, when having to superintend post-mortem examinations, supplies me with many instances in which pain and death might seemingly, according to more recent experiences, have been obviated by abdominal puncture.

[10] A French writer, when describing the successful issue of the operation, speaks of the relief obtained as "soulagement miraculeux."

[11] By way of demonstrating the power with which the gas was expelled through the trocar by the contracting intestine, I might adopt the expression of several writers, as well Latin as French, who constantly speak of the current of gas as being sufficiently strong to "blow out a candle." M. Mothe, to whom I allude elsewhere, after describing a case, writes as follows: "La ponction fut faite, et à peine la trocart fut-il rétiré, que l'air sortit impétueusement, et éteignit plusieurs fois la chandelle." It would seem that this experimental method of extinguishing a candle may at times cause a little consternation, as Sir W. Jenner has told me of a case operated on by Mr. W. Adams of Regent's-park in which the air passing through the trocar caught fire on the application of a lighted candle. And I have heard from him, and from others also, that it is known that stable boys have a trick of holding a lighted candle to the anus of horses and watching the gas which escapes taking fire. Indeed, serious fires in stables have been attributed to such tricks. I have also learnt that gas escaping from man by the same exit is at times inflammable. This, of course, suggests the question as to what may be the chemical composition of the gas liberated from the bowels which permits it to burn. Magendie and Chevreul examined the gases which were found in the large intestines of two criminals to consist principally of carbonic acid and nitrogen gas, with varying small quantities of hydrogen and carburetted hydrogen, and a small quantity of sulphuretted hydrogen. Laycock, in his work on the "Nervous Diseases of Women," alludes to the case of a lady who used to pass enormous quantities of gas daily from the stomach, which was found to contain 50 per cent. of nitrogen. The latest reliable analysis, I believe, of intestinal gases is that of Ruge (quoted in physiological works), who in 1862 found the gas of the large intestine in man to be tolerably constant after different kinds of food—nitrogen preponderating after the use of flesh, hydrogen after milk, and carburetted hydrogen after vegetable diet, a slight amount only of sulphuretted hydrogen existing. We have only to suppose, under disease or after certain kinds of food, a certain definite proportion of hydrogen and carburetted hydrogen to exist, and then the admixture would be inflammable. Professor Robertson, of the Royal Veterinary College, Camden Town (referred to elsewhere), tells me that the inflammability of flatus in certain states of tympany in the horse is well known, and that he has himself seen it lighted when escaping from the anus. In the case of a horse operated on by Barrière in 1783 (alluded to elsewhere) it is specially stated that the gas rushing out from the trocar caught fire from the lighted candle.

whose works I have found in our libraries, I will allude, firstly, to the observations of De la Font. In his "Dissertatio Medica de Hydrope Tympanite"[13] (Geneva, 1697), after quoting various authors on the subject, and especially controverting the opinions of Willis, that tympanites was convulsive in its nature (himself contending that it was fermentative), he alludes to its cure, if other means fail, by *puncture*. He also quotes Duretus as being in favour of the "compunctio seu punctura" in tympanites. In passing, I may say he alludes to the statement of Paulus Ægineta (a view held by many more recent writers), that by means of cupping glasses the air can be drawn through the walls of the abdomen, "per poros cutis," "et quasi incantamenti vice, ut loquitur Galenus."[14] The brilliancy of imagination which is here apparent is also shown by Galen, who thought that the ethmoid bone was pierced by holes in order to permit communication between the brain and throat, and for purging the brain from superfluities.

Boerhaave, writing in the early part of the eighteenth century upon wounds of the abdomen,[15] alludes to the necessity of puncturing the intestines with a needle to evacuate the air, and then observes: "Quod nihil nocet, quia quando intestina sunt difflata, tunc se retrotrahentia illas puncturas claudunt." And in his Aphorisms, writing of tympany as "dry dropsy," he says that it never cures, yet paracentesis has sometimes given ease.

About the middle of the same century, F. de P. Combalusier, in his "Pneumato-Pathologia, seu Tractatus de flatulentibus humani corporis affectibus," has a section entitled "Num peragenda in Abdominalis Tympanite Paracentesi," followed by another, "Cautelæ in Tympaniticorum paracentesi observandæ."

Later in the same century (1788), W. Trnka, in his "Historia Tympanitidis (Vindobornæ)," has a chapter headed "Paracenthesis," in which he presents and compares the views of many recent authors on the subject; and also one styled "Autlia Pneumatica," in which he suggests that with due caution an autlia (that is, a suction or air pump) might be applied to the anal orifice, for the purpose of drawing out the gas contained in the bowel.[16] In the former section, he refers to certain experimenters having found that in the case of those who had died with excessive tympanites (especially Ballonius),[17] upon piercing the abdomen with a very small instrument, air rushed out, and the whole abdomen suddenly collapsed, and who consequently asked, "An non viventi metu repentinæ mortis ista punctio fieri et potuit et debuit? Audendum hercle (ait) desperatis maxime rebus."

At the beginning of the present century, Callisen, a Danish author, in his "Systema Chirurgiæ," &c., in a section upon Tympanites, writes: "Exclusio aëris punctione abdominali simplici, insigna quidem levamine beare solet miseros." He then proceeds to say that the relief is not permanent, owing to the reaccumulation of air.

In 1812, M. Mothe, of Lyons, published a rather lengthy memoir on Tympanites, in a work called "Mélanges de Médecine et Chirurgie," in which, after enumerating seven varieties of tympanites (according to the classification of Sauvage's Nosology),[18] and quoting from many authors as to what was known of the disease (such as Lieutaud, Swart, Pomme, Levret, Litré[19]), and showing how they differed respecting the utility of abdominal puncture for its relief, he gives precise information as to its performance, the time and the locality most suitable for its use, and the kind of instrument to be used. He distinctly states that the over-distended bowel may recover its tone after the evacuation of the air, in the same way as the over-distended urinary bladder does, after relief has been obtained by discharge of retained urine. He concludes that in "essential" tympanites—that is, when the affection is not merely a symptom or accident of some grave disease—it would be in the highest degree inhuman and culpable, when other means have failed, to abandon the patient, and not to resort to puncture as a last resource.[20] And he quotes the practise of relieving tympanites in cattle (so often caused by eating wet "luzerne") by puncturing the abdomen, thus only preventing death.

In 1818, C. B. Zang, in a work published at Vienna, on Surgical Operations, has a chapter[21] in which he gives detailed notice of "Paracentesis Tympanites."

In 1835, Dr. Roche, writing in the "Dict. de Méd. et Chir.,"[22] though considering the operation to be a dangerous one, quotes certain cases which were attended by success. In the *Bulletin de l'Acad. Royale de Méd.*, 1843-44,[23] a case is related by M. Levret in which intestinal tympanites was cured by puncture of a part of the small intestine with a trocar of the size of a knitting-needle.

In the year 1845, Mr. Teale, sen., of Leeds, in his address before the Provincial Medical and Surgical Association, observed that paracentesis, by a fine trocar, of the intestine for tympanites had been successfully adopted by Sir H. Marsh and by M. Levret for its relief; and Dr. Littleton of Plymouth, in a communication later on, pointed out that about this time Sir P. Crampton and Mr. Cusack (of Dublin) had sanctioned the operation.[24]

In 1852 Labric published a thesis ("De la Ponction abdominale dans la Tympanite") in which he put together the various facts which he had met with in connexion with the operation, and gave his conclusions deduced from them. He recognises the two varieties of tympanites, peritoneal and intestinal, and gives their causes, symptoms, and treatment, quoting especially Chomel[25] and Piorry[26] as to the source of the gas in the former variety. He notices that the operation is often resorted to successfully by veterinary surgeons in the case of cattle on the point of death, after they have eaten large quantities of moist food, especially trefoil. He observes that in man not only does the operation, when necessarily resorted to, give relief to distressing symptoms, but that it renews to the distended and enfeebled intestine its contractile power, and enables it to discharge its contents, in the same way as in retention of urine the bladder's power of contraction is restored by drawing off the urine,[27] and as the contraction of the parturient uterus is facilitated by removal of part of its contained fluids. Labric quotes Levret and Maisonneuve as having seen a return of the peristaltic action of the bowel upon the free evacuation of flatus following puncture; and he remarks that peritonitis is almost the only accident which one has to anticipate from the intestinal puncture; and this, he observes, has caused many to look upon the operation with disfavour. This peritonitis, he says, does not seem to be owing to injury to the peritoneum by the instrument, but is the result of escape into the cavity of fæcal matter. In this he is supported by Jobert, who, in his treatise on Wounds of the Intestinal Canal, says that when sharp instruments penetrate directly the intestine without tearing it, the edges close, and the space produced by them disappears when the instrument is withdrawn; and he considers acupuncture of the bowels to be free from danger. In a case of typhoid fever in which the intestinal puncture was made to relieve tympanites, no traces of puncture in the walls of the bowels were ascertainable after death. He quotes Mérat, Paré, Law, and v. Swieten, who practised acupuncture of the bowels in

[13] In many of the old writers what we call tympanites was considered a form of "hydrops," and was often called "hydrops sicca" in opposition to "hydrops ascites."

[14] De la Font's remarks open a somewhat quaint way of evacuating the air from the distended bowels recommended by some—viz., the exhausting it by the rectum. He observes: "Sunt qui putant *fistulâ clysteris* in podicem immissa sine ullo liquore, et frequenter agitato instrumento illo impulsorio dicto magnam flatuum copiam educi, modo flatus in intestinis contineantur, vel *follis fabrilis* clausus ano adaptatur, et deinde elevatur, sic enim flatus in intestinis contenti, modo pertinax aliqua obstructio in ipsis non adsit, in follem vel fistulam clysteris prædictam impellentur, quæ omnia experiri licebit."

[15] See his Praxis Med.

[16] Dr. Laycock, in his "Treatise on the Nervous Diseases of Women," quotes Kerr as saying that Dr. Osborne and Dr. Graves had continued the practice of using the air pump for abstracting the gas.

[17] Heister Meroklinius. [18] Tome xi., Cachexies.

[19] Who stated that he had seen the colon so distended as to be equal to the thigh in diameter, and the whole intestine four times its ordinary volume.

[20] He would thoroughly endorse the views of Bacon, who blames physicians for not making the *εὐθανασία* a part of their studies, as quoted by the first Heberden and by Watson. Heberden, speaking of the duties of the physician, remarks: "They should try to disarm death of its terror; and if they cannot make him quit his prey and the life must be lost, they may still prevail to have it taken away in the most merciful manner."

[23] Art. Tympanite.

[24] Brit. Med. Jour., November 4th, 1871. With regard to the practice of these eminent Irish surgeons I find it stated in a lecture by Dr. Houston on Modern Improvements, published in THE LANCET of Dec. 1884, that Sir H. Marsh was in the habit of relieving excessive distension of the abdomen from flatus, without any bad effect, by pricking with a small trocar; and that he knew a lady on whom Mr. Cusack operated several times in this way, in consultation with Sir H. Marsh and Sir P. Crampton, and each time with great relief. Of any association between these gentlemen and the operation I regret to say I can find no written record.

[25] Dict. de Méd. [26] Dict. des Sciences Méd.

[27] In a note to his memoir alluded to above, M. Mothe remarks that he knew a woman who had had retention of urine for fourteen days, during this time the urine only escaping by overflow. The bladder eventually entirely recovered its natural powers.

Digitized by Google

cases of strangulated hernia. As a means of puncturing the abdominal walls, Labric recommends the trocar in preference to acupuncture, as by means of the cannula the gas may continue to escape; and he gives important surgical directions as to the mode of conducting the operation, incision of the skin being often required before the plunging in of the trocar. Considering what grave evils may be caused by excessive distension of the abdomen, the author gives a warning *against delay* in operating. Of course, he observes, if the distension is from gas in the ileum or stomach, an œsophageal or long intestinal tube may give relief. He has never seen any case of puncture for *peritoneal* tympanites, but quotes some instances from various sources.

In 1858 a case was published in the *Moniteur des Hôpitaux*[28] in which death, which seemed to be inevitable, was averted by puncture of the bowels, which were enormously distended by flatus, after other means had failed. Three or four litres of gas escaped by the puncture, with a loud noise.

In 1860 Dr. Olivieri published in the *Gazz. Lomb.* (29) a description of twenty cases which he had met with in Bolivia, South America, of acute tympanites caused by improper food, in which he had punctured the stomach. Of these, eight recovered, the others dying, "probably from not having been submitted to treatment until too late."[29] And in 1868 Bricheteau, after alluding to the discussion on the merits of the operation by Fonssagrives and Ripoli, reported in the *Bull. Gén. de Thérap.*, vol. lxxiv., p. 327, an interesting case in which Dr. Bouley had ordered it to be done at the Necker Hospital. The punctures were made on three separate occasions, and were attended by absolute relief to the patient and followed by free alvine evacuations.

(To be continued.)

ON LATERAL CURVATURE OF THE SPINE.

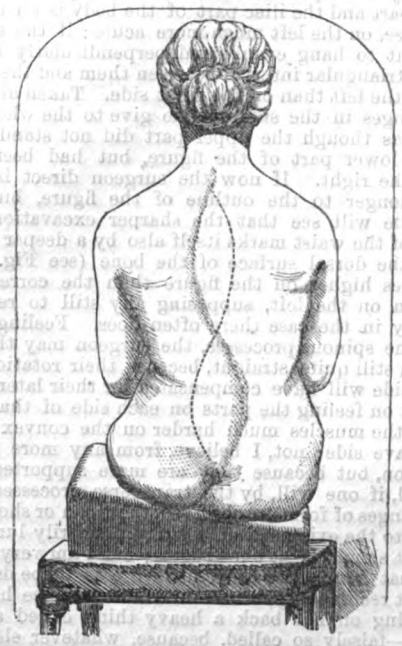
BY RICHARD BARWELL, F.R.C.S.,
SENIOR SURGEON, CHARING-CROSS HOSPITAL.

No. II.

IF in my last paper I made myself understood—if I made it clear how what at first is merely a muscular condition[1] gradually invades the ligaments, and then the as yet immature epiphyses of the spine producing deformation of the vertebræ—if, I say, this was made clear, it must be evident to all careful parents and to all trusted medical advisers that a periodical inspection of growing children should be made, more especially if those children be subjected to the high-pressure system of modern school teaching. Nor must it be thought that as long as parents do not observe a shoulder to be high or thick, a hip to protrude, or the dress to hang lower on one side, therefore all is well; a spinal curve, when visible through the clothing or detectable by a dressmaker's tape measure, is already sufficiently advanced to render treatment certainly prolonged, perhaps doubtful. The earliest signs of curvature are very subtle, only noticeable to the trained eye, and even by many of the profession not much accustomed to this special examination are—I must be pardoned for saying it—little understood. It will therefore be well to give, in the shortest words I can command, a description of these earliest symptoms. Firstly, of lumbar curvature, convex—let us assume to the right. The patient is placed with the back directly opposite a good light, cross shadows and reflections being avoided; the hair must be disposed on the head; the clothes removed, only a chemise and perhaps an under-vest retained, and these dropped to a level with the great trochanters; all embarrassment from tendency to slip lower, and all restless wringing of the body, must be avoided by [illegible] arrangement.[2] The surgeon, sitting behind her, finds that the knees are quite straight, the feet close together; then places his forefingers on the crest of the ilium at the side where the curvature is to be higher than the other. He will [illegible] if he arrange that the horizontal line of a dado or some piece of furniture crosses, at a greater distance from his eye, the figure at this level. Having settled one way or the other this point, he may recede a little, the better to take in the whole contour of the figure from the nape downwards, and will see that it is different on each side; on the convex side (in the case postulated the right) the side outline just above the ilium is full and rounded, while on the concave side the constriction of the waist is marked by a deeper excavation; the angle between the thoracic part and the iliac part of the body is on the right very obtuse, on the left much more acute; if the arms can be brought to hang evenly and perpendicularly from the body the triangular interval between them and the trunk is larger on the left than on the right side. Taken altogether, these changes in the side outline give to the whole figure the look as though the upper part did not stand straight over the lower part of the figure, but had been shifted over to the right. If now the surgeon direct his attention no longer to the outline of the figure, but to the surface, he will see that the sharper excavation on the left side of the waist marks itself also by a deeper indentation on the dorsal surface of the bone (see Fig. 5), and that it lies higher on the figure than the corresponding depression on the left, supposing any still to remain, as very early in the case there often does. Feeling for the line of the spinous processes, the surgeon may thus early find them still quite straight, because their rotation to the concave side will have compensated for their lateral deviation; but on feeling the parts on each side of that line he will find the muscles much harder on the convex than on the concave side; not, I believe, from any more powerful contraction, but because they are more supported, pushed backward, if one will, by the transverse processes. When these changes of form are observed, there can or should be no doubt as to the existence of a curve primarily lumbar, and treatment should be at once begun; but I am very far from saying that henceforth the child's life is to be devoted to persistent recumbency, or that she is to sacrifice her health by carrying on her back a heavy thing called a "spinal support"—falsely so called, because, whatever else it may support, it cannot so act on a deviated spine. On the contrary, I recommend, more especially for quite young patients, a treatment which makes very slight demands upon their time or comfort, but which after a little steady perseverance greatly modifies the curve, which in a certain period, commensurate with the severity of the case, will cure it; and which can have no injurious effect upon the health.

The particulars of this treatment are as follows. Firstly, let me refer to my previous paper. Fig. 1 represents a case of permanent pelvic obliquity from shortness of one lower limb; the spine is necessarily curved to the left. Fig. 2, from the same patient, shows how a block of commensurate thickness placed under the short limb corrects the pelvic obliquity, and therefore also the spinal curve; this latter correction was not, of course, obtained at once, but is the fruit of the plan carried on for some weeks. The deduction is obvious—viz., in every case in which by the means above described pelvic obliquity is detectable, to heighten the lower side of the pelvis until it is on a level, or in certain cases above the level, of the other side. But we need not stop there, for if pelvic obliquity can produce, as has just been proved, a lumbar curve, therefore an already existing curve can be counteracted by making the pelvis oblique—higher, that is to say, on the convex side. In early and slight cases the spine assumes, while this artificial pelvic obliquity is maintained, a perfectly straight line, or the curve may be actually reversed.[3] Older and severer cases cannot be thus immediately straightened, but they are very considerably corrected, and that correction is week by week confirmed and increased. Thus I order the heel of the boot on the convex side to be somewhat heightened, or rather arrange that the heels of the boots or shoes be broad and flat—really under the foot-heel, not pointed and in the middle of the foot, as is the present fashion; and I direct that one thickness of leather be taken from that on the concave, and that one be added to that on the convex side. Moreover, I order a hollow wedge of wood, made of two boards screwed together at one end and separated at the other by a cross-piece.[4] This wedge may be covered with plush or worsted

[illegible] Times and Gazette, p. 539.
[illegible] Society's Year-book, 1861, p. 213.
[illegible] that the muscles are primarily in [illegible] to my former paper for the explanation [illegible]
[illegible] webbing passed round the body and [illegible] I have found to be the simplest plan.



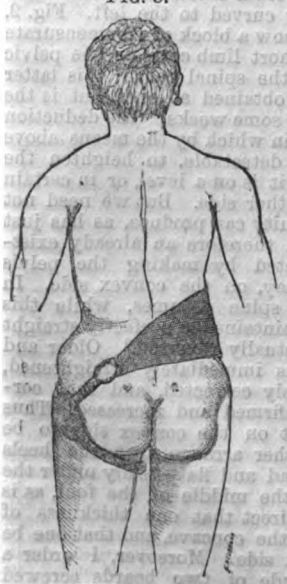
[3] In practice it is, as a rule, undesirable to reverse the curve, as thereby the ligaments are rendered, as it appears to me, loose and flaccid.

[4] The dimensions are 14 in. long, 11 in. broad; elevation at one end from 1½ in. to 2 in., according to the case.

Digitized by Google

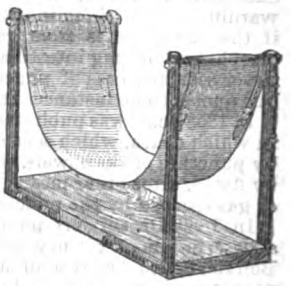
work. It is to be placed on the seat of a chair, and the patient sits on it with the higher side towards the convexity of the spine (Fig. 4), thus by degrees forcing the column to assume a straight line or a contrary curve. This cannot, however, be used in the first part of the case for very long at a time, but rather for several short periods during the

FIG. 4.



The dotted line represents the morbid curve, the shaded line that which the artificial pelvic obliquity tends to produce.

day. Hence it is convenient to let the patient sit on it during meals. For quite young subjects with commencing curves these methods often suffice.



But in more developed cases some power which shall draw the convexity over to the concave side is required, and for this purpose I employ a device which I have named the *loin bandage*. It is in each instance made of coutil or moleskin, from a pattern which I myself cut to the patient's figure. The patient takes it off and puts it on by clasps (except the leg strap), its tension and balance being regulated by buckles provided with a simple mechanism that ensures to me their control. Elasticity is obtained by inserting, back and front, indiarubber rings an inch and a half in diameter, made of cord fully a quarter of an inch thick. (See Fig. 5.) This is not worn next the skin, as represented in the figure, but outside a combination garment, or, if drawers and chemise be separate, a slit in the side-seam of the latter allows the loin part to lie outside. I need only add that the hip pad should lie in the depression behind the trochanter, and in putting it on the back ring should be strained tighter than the front one. When the balance is arranged aright, the whole sits very comfortably, and does not show under the garments. A very small percentage of patients feel for a day or two the strap round the leg; they very soon lose the sensation, for there is really no tension on it, the force of the loin part acting at an acute angle with the direction of the leg strap. Rarely is any other device than those above named required, but in really severe cases two others may be added.

FIG. 5.

The *lateral swing* is a mechanism that I used for some years before giving any account of it. (Fig. 6.) Dr. Busch and I seem to have published it simultaneously. I chiefly use it in dorsal curvature, but also occasionally in lumbar. It is fourteen inches long by six broad and ten high; it should therefore be kept at the bedside, and when the patient retires for the night she lies in this for about twenty minutes, so that the convex side of the spine is slung up off the bed by the broad webbing, and must curve in the contrary direction. Again, in the morning, quite early, the maid or nurse can hand this into the bed, and the patient can lie and take an additional sleep in it.

FIG. 6.

The *loop girth* is simply a piece of broad webbing about four feet long, fastened by each end to a staple in the wall a little above the level of the patient's waist; she stands with the concave side towards the wall; the convex side is caught in the loop, the foot on that side being supported by a block from one to two inches high. When the girth is found to be properly secure, she places her clasped hands on her head and slowly bends over; then rises again and repeats this manœuvre several times, gradually increasing the number, as also the rapidity, of the movements, as custom renders them easier. Very few, if any, lumbar curves resist these combined remedies.

In my next paper the more difficult subject of dorsal curvature will be discussed.

CANCER OF BRONCHIAL GLANDS AND LUNG.[1]

BY M. A. BOYD, M.C.P. IREL.,
PHYSICIAN TO MATER MISERICORDIÆ HOSPITAL, DUBLIN.

IN bringing forward the subject of cancer of the bronchial glands and lung I am not calling attention to any new subject, but I think I may venture to assert it is a subject the importance of which cannot be exaggerated, and the difficulties in the diagnosis of which all physicians must admit. From the enormous amount of adenoid tissue within the thorax, and the well-known affinity cancer has for that structure, we should reason *a priori* that intra-thoracic cancer should be of not unfrequent occurrence, and from the marked similarity between it and phthisis, especially the so-called senile variety of phthisis, in many of its symptoms, the existence of the disease is, I am convinced, frequently overlooked. The characteristic symptoms that are said to indicate intra-thoracic cancer of either the mediastinum or glands, such as fixed pain in the chest, red-currant-jelly expectoration, and enlargement of cervical glands, are not present in a fourth of the cases, while symptoms that indicate phthisis are present in the great majority of them, and in some the presence of cancer is not even suspected until widespread infiltration of either the lung, pleura, or pericardium reveals its existence. Enlargement of one or more cervical glands when present, with symptoms of a tumour within the thorax, not aneurysmal, would be to us conclusive of the presence of cancer, but this evidence is more often wanting than not. The same remarks apply to the existence of pain, which is seldom present to any extent until symptoms of pressure on the large nervous trunks occur, and this is generally so late a symptom that all doubt as to the nature of the case is set at rest before pain becomes a prominent symptom. Red-currant-jelly expectoration is in my experience a very rare symptom. I am aware that in these assertions I am not in keeping with the generally received opinions on the subject, but unfortunately

[1] Read before the Academy of Medicine in Ireland, May 28th, 1886.

Digitized by Google

every-day experience proves to us that generally received opinions are often erroneous, and we find often when it is too late that all the statements in standard works are not invariably to be relied on; especially so is the generally accepted one that cancer of the lung or mediastinum is generally secondary to cancer in other organs, so that our conclusions are unsatisfactory even where symptoms arouse our suspicion, and we look for its presence elsewhere—generally not to find it.

Cancer of the bronchial glands and lung, in my experience, nearly always begins as primary cancer in these situations, and very rarely as secondary infiltration from other parts, and where it is secondary there is generally well-marked engagement of the lymphatic system in other situations before it becomes intra-thoracic. The intra-thoracic situations where malignant disease is met are two—namely, the bronchial glands and the lung, and anterior mediastinum. The former situation is from a clinical point of view the most important, as malignant disease in these structures, simulates phthisis in a subacute form so closely that its differential diagnosis in some cases is almost impossible. From observation of a good number of cases I am convinced this is so, and a case of malignant deposit in the bronchial glands, infiltrating the lung, ending in ulceration and in the formation of cavities, is frequently set down as one of hopeless phthisis, a post-mortem on which would be of no interest, and all record of the frequency of the disease is in consequence entirely lost. With mediastinal cancer such an error is not so likely to occur, as, like other intra-thoracic growths, such as aneurysm, the symptoms are more the result of the pressure it exercises on the important vascular and nervous structures around it, and which attract attention long before infiltration of the lung and general cachexia show themselves. Added to this, the growth is more superficial and more easy to be recognised. With the former variety lung symptoms predominate; with the latter cardiac and vascular ones. Hæmoptosis appearing early, and being constant in its occurrence, would seem to be the most reliable sign, and was present in more than half of thirty-nine cases recorded by Dr. Risdon Bennett in his Lumleian Lectures on Intra-thoracic Cancer, and Dr. Walshe speaks of it as having occurred at some period in nearly all of his cases. When persistently present it affords evidence of the situation of the growth in the bronchial glands or in the lung itself, with pressure on the bronchial veins, as distinguished from mediastinal cancer, which latter, as Dr. Cockle remarks in his work, may afford no evidence of its existence until pressure symptoms, or infiltration of the surrounding parts, especially the pericardium or large vessels, indicate the presence of a tumour within the thorax.

I will now confine my remarks principally to the symptoms that indicate cancerous engagement of the bronchial glands and lung and their similarity to phthisis, and afterwards to those that indicate engagement of the mediastinum. I have mentioned hæmoptosis as a constant and oft-recurring symptom. Next in importance, as pointed out by Dr. Rossbach, would seem to be early congestion of the larynx, with aphonia, and without paralysis of the vocal cords, which latter symptom I will allude to afterwards as conclusive of mediastinal cancer. Spasmodic cough, with very little expectoration in proportion, as indicating early irritation of the bronchial nerves, frequently accompanied by dyspnœa and vomiting, is another early symptom. Next, dulness on percussion over some portion of the chest anteriorly; but this is not always present in the early stages of cancer of the bronchial glands, though it is the earliest symptom in mediastinal cancer. Feeble respiratory sounds on one side, bronchial râles, tubular breathing, prolongation of [illegible] sounds, and symptoms indicating [illegible] of the bronchial tubes, are frequently [illegible] difficulty in swallowing from pressure on the œsophagus, with cough and vomiting excited by the effort, [illegible] over the upper portion of the sternum, [illegible] drawn back, as pointed out by [illegible] describing the symptoms indicating [illegible] might be placed next in order. [illegible] one or the other side, containing [illegible] infiltration. This latter phenomenon [illegible] of intra-thoracic cancer, [illegible] of the pleural fluid as well [illegible] usually gives negative [illegible] the characteristic cells. [illegible] symptoms in advanced cases and in old people muco-purulent expectoration, emaciation, night sweats, and a moderately high temperature, we have a chain of phenomena that resemble phthisis.

When cancer begins in the anterior mediastinum there may be no cough whatever in the early stage, but there is marked retro-sternal dulness, with sense of resistance, and generally retro-sternal pain. Here pressure symptoms begin to show themselves early, as indicated by displacement of the heart, fulness of the veins in the neck, with cyanosis and œdema of the face and upper extremities, and later on dyspnœa, with stridulous breathing, aphonia, and paralysis of one or other of the vocal cords, as the vagus or recurrent laryngeal respectively get pressed on. Paralysis of one or other of the vocal cords, with symptoms of a tumour within the thorax in the absence of aneurysm, is regarded by Dr. Burney Yeo as absolutely diagnostic of malignant disease. Though the symptoms of cancer of the bronchial glands resemble phthisis very closely, we shall find in the signs occasionally features that raise doubts in our minds as to their being phthisical ones. The dulness on percussion is generally not apical, but lower down over the lung, and is elicited posteriorly opposite to the same situation in front, and is generally more extensive than in phthisis, when the disease is of some duration. There is also generally an absence of all crepitus, though bronchial râles and feeble inspiratory sounds, with prolongation of expiration, are present. When the bronchial glands are much enlarged and compress the bronchi, vocal fremitus and vocal resonance are both absent; and absence of all breath sounds with collapse or consolidation of the lung generally present a condition you will not find in phthisis, no matter how extensive the consolidation. Though many of the above symptoms are present in a good number of the cases of primary cancer of the bronchial glands, in some one of the symptoms will be most marked, and the first of the following cases illustrates the prominence of pleural effusion over all other symptoms.

John G——, aged thirty-eight, a bottle-blower by trade, was admitted into the Mater Misericordiæ Hospital on the 27th of July last, suffering from cough, dyspnœa, lividity of the face, and slightly bloody expectoration. He never had syphilis, rheumatism, or any other illness, though he drank hard at times, and was able to attend to his work, in which he was constantly exposed to draughts for a period of fourteen hours at a time. There was no history of malignant disease in his family. Three weeks before admission, while engaged at his occupation, he caught cold, which showed itself by prolonged rigor, sickness of stomach, and headache with feverishness; he also felt pain of a catching character in the right mammary region. He was confined to bed for a few days with these symptoms; but after this time was able to attend to his work again, experiencing only slight pain in the right side, cough, and shortness of breath. For a week before admission these symptoms became worse, and on admission he presented the following:—Lividity of the lips and face, with puffiness of the eyelids and prominence of the veins on the front of the thorax and also in the neck; no enlarged gland to be seen. His voice was hoarse and aphonic, and there was urgent dyspnœa, especially on exertion, with cough and bronchial fremitus over the chest. The patient seemed in no way emaciated, and did not suffer from night sweats. There was absolute dulness on percussion over the entire aspect of the right chest, except for an inch or two under the clavicle, where it was tympanitic; and behind, the dulness reached as high as the centre of the scapula. In front it encroached across the upper portion of the sternum to the extent of an inch or two beyond its left border, and here the dulness gave great sense of resistance. There was feeble inspiration through the right lung, with bronchial râles in both; and vocal fremitus and vocal resonance were both absent on the right side. The heart was feeble in its action, but not displaced, and no murmur was present either in it or the great vessels. From enlarged measurements of the right side and the above symptoms I considered there was fluid in the pleura, though I could not explain the symptoms of venous pressure from this alone, and could only conjecture there was a tumour within the thorax also. I aspirated the right pleura on the day after his admission, removing nine pints of fluid, the latter portion of which was bloody. After removal of the fluid the dulness was more distinct over the upper portion of the sternum, and could be defined. His dyspnœa was considerably relieved, and more air seemed to enter the

Digitized by Google

right lung, cyanosis of the head and face, however, continuing, and the veins on the thorax showing more prominently. A week later his right arm and face became very swollen, and, recurring dulness over the right side indicating fresh effusion, I again tapped the pleura and removed six pints of bloody fluid. Some days after the second tapping his temperature rose, his dyspnœa increased, and dulness at the base of the left lung showed itself. Suppression of urine with delirium set in, and he died on August 18th. The post-mortem examination showed a large mass of cancer, both hard and medullary, infiltrating the bronchial glands and lung on the right side, beginning at the bifurcation of the trachea, and involving in its course the pleura, which was thickened, lymphy, and contained a quantity of bloody serum, and infiltrated the pericardium over the auricle, the superior cava of which it compressed. The left lung was congested throughout, and solidified around its main bronchi from recent inflammation.

The following case, in which symptoms of phthisis with difficulty in swallowing were the most prominent features, shows a different train of symptoms:—

James McC——, a waiter, aged thirty-seven, was admitted into the Mater Misericordiæ Hospital on Sept. 22nd last, complaining of cough, with muco-purulent expectoration mixed with blood, night sweats, emaciation, and symptoms of stricture of the œsophagus. The patient gave a good family history; there had been no phthisis on either side. He drank freely, taking as many as eight or ten glasses of whisky daily, undiluted. He had never suffered from any illness until six months before admission, when he noticed a difficulty in swallowing his food, accompanied by cough and vomiting, the food being arrested at a spot which he referred to the centre of the sternum. There was no pain at the place of constriction, and no sense of pressure or dyspnœa. He coughed up frequently considerable quantities of blood, bringing up nearly half a pint six weeks before admission, occasionally being jam-tinted or prune-juiced in colour. On examination the heart was found healthy; no murmur. There was no enlargement of the cervical glands. The throat was congested and the voice aphonic. Dulness was elicited over the upper portion of the sternum, extending to the subclavian space on the right side, with tubular breathing and bronchial râles, but no crepitus. There was no dulness posteriorly, the breath sounds being normal here. An œsophageal tube of the smallest size could be passed, and the stricture only admitted the next size up to the time of his death; all attempts to pass a larger one failed. After catheterisation liquid nourishment could be taken, but it always induced cough at first, ending in vomiting. The temperature throughout varied, rising occasionally from normal to 101·2°. His emaciation and night sweats increased, the tube being passed daily to allow of nourishment being taken until Oct. 17th, when the dulness over the upper portion of the sternum and right apex showed a marked increase, and on the 21st no tube could be passed, the attempts to do so causing considerable pain. Pulmonary congestion set in, and the patient died on Oct. 28th. I regret that in this case no post-mortem examination was allowed, as we should no doubt have found enlarged cancerous bronchial glands pressing on and constricting the œsophagus springing from the fork of the trachea, which would seem to be the most usual site for cancer in this situation to begin.

The next case, a washerwoman, aged fifty, was admitted into my ward in the hospital with feverish symptoms, pain in the left side, dyspnœa, wasting cough, and muco-purulent expectoration mixed with blood, which was constantly present. The patient was seen in my absence by the assistant physician, who diagnosed pleural effusion of the left side, with dulness on percussion at base, absence of vocal fremitus, and resonance. Though no dulness existed in the upper portion of the lung, there was complete absence of all breath sounds here, which seemed rather difficult to explain. The woman showed marked hectic flush, and dyspnœa existed out of all proportion to the pleural effusion. Her illness began about three months previously with pain in the left side, a cough that had existed for some months before, with blood-spitting; but the symptoms were not urgent until a few weeks before admission. There was dulness in front behind the upper portion of the sternum, extending to and becoming continuous with cardiac dulness, but the percussion over both apices was normally clear. The respiration was puerile at the right apex and over the right lung; but there was complete absence of all respiratory sounds over the left apex. The dyspnœa and orthopnœa were most troublesome, and the temperature remained high up to the time of her death, which occurred three weeks after her admission. The post-mortem examination showed dark-coloured serum in the left pleural cavity to the extent of two or three pints. The pleura and lung were adherent at its upper and anterior aspect, with a thickened mass of hard bronchial glands surrounding the root of the left lung, compressing the bronchi and bronchial veins. The lung itself was contracted to half its size, and puckered here and there from emphysematous lobules, and the upper lobes studded in places with cancerous nodules, both medullary and scirrhous, which spread in a radiating manner from its root; between these the lung was solidified and non-crepitant.

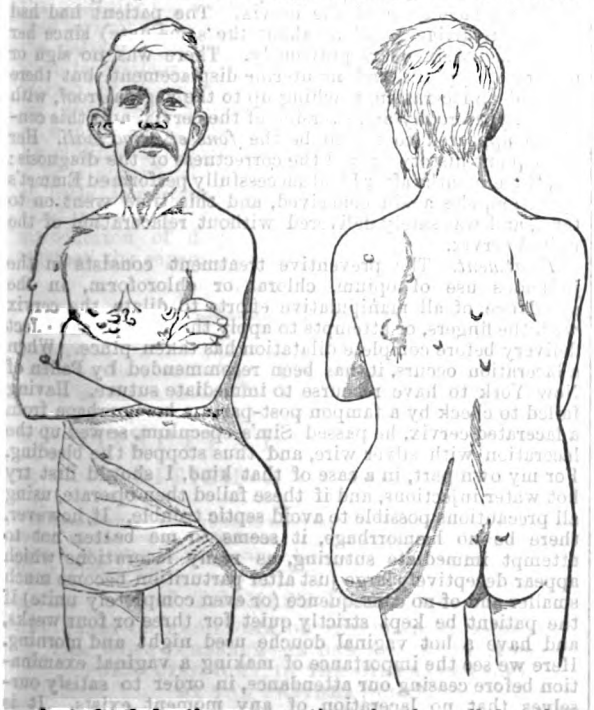
I may mention that in both these cases microscopic sections of the deposit showed the typical cells. And in the first two cases, though aphonia and congestion of the larynx were present, there was no paralysis of the vocal cords evident. I need not here allude to secondary cancer occurring in these situations, my object being to show that primary cancer is of the two much more frequent, and that in advanced cases it is likely to be confounded with phthisis.

The general conclusions I have come to with regard to the disease are as follows: That primary cancer of the thorax is of not unfrequent occurrence, generally appearing in hard drinkers, and the symptoms of it are developed apparently after catching cold. That it is to be found in two situations within the thorax—namely, the bronchial glands and the anterior mediastinum; and is of the mixed variety, scirrhous and encephaloid. That persistent blood-spitting is a very usual symptom in its growth, and indicates infiltration of the lung and pressure on the bronchial veins; and that the so-called characteristic red-current-jelly expectoration is a rare symptom. That fixed pain in the thorax is not always present, and when it is, it is more usual in the mediastinal form of the disease. That the disease is generally accompanied by aphonia and congestion of the larynx in its early stages, and by paralysis of one or other of the vocal cords in a later stage. That when in the bronchial glands it is invariably accompanied by symptoms of pressure on either one or other of the bronchi, or on the œsophagus, causing symptoms of stricture. That pleural effusion containing blood is very frequent on the side affected, and in its growth forwards from the root of the lung it involves the pericardium, and causes pressure on the superior cava or pulmonary veins. That when in the bronchial glands its later stages may simulate advanced phthisis very closely. That it may be occasionally distinguished from phthisis by its pressure symptoms on the bronchi, its dulness being more central and more extensive, with absence of crepitus and more urgent dyspnœa, while no bacilli are found in the expectoration. That malignant intra-thoracic disease is generally fatal in from two months to six, though Dr. Walshe gives the average duration as from three months to thirteen. In the cases I have just mentioned the disease was fatal in each case within seven months. I need not here allude to the difficulty in distinguishing between intra-thoracic malignant disease and aneurysm, where no murmur is present and pressure symptoms are the most prominent feature in the case. The difficulties of forming a differential diagnosis in such cases are indeed great—nay, sometimes almost impossible,—and we have mainly to rely on the evidence afforded by arterial disease elsewhere to assist us.

MOLLUSCUM FIBROSUM AND LARGE PENDULOUS FIBROMA;

REMOVAL OF GROWTH; RECOVERY.

By HENRY A. LEDIARD, M.D. Edin., F.R.C.S. Eng.,
SURGEON TO THE CUMBERLAND INFIRMARY.



John G——, aged twenty-nine, labourer in a timber yard, was admitted into the Cumberland Infirmary on March 17th, 1886. The patient has never been what is called "quick," and his head has always been very large in proportion to his body. He has had none but ordinary illnesses, with the exception of bronchitis, from which he suffered for the previous three months. He has had from birth a tumour over the left hip, which continued to grow till he was twenty-four, when it ceased growing. In addition to this, he has developed numerous small tumours on various parts of the

Digitized by Google

body, and he has never had any pain except when some of them have suppurated; but this has not occurred often.

On admission the patient was considerably emaciated and suffering from chronic bronchitis. Studding the upper two-thirds of his body were several tumours varying in size from a split pea to a chestnut, with the exception of the large one about to be described. They were all of them rounded and smooth surfaced, some moving freely beneath the skin, others adherent; many of them had a bluish tint. In two instances these tumours had suppurated and formed abscesses. There was one small tumour behind the left ear, of the size of a split pea; another on the right side of the neck, rather larger; there were several varying in size over the whole back, particularly about the sacrum; some were to be found on the arms and forearms, but none were seen below the trochanters. Situated over the left iliac bone was an enormous pendulous growth, hanging from the tissues about the left crest of the ilium and the left inguinal and lumbar regions. The tumour hung like a satchel, it was ten inches long and about fourteen inches broad at the base. Its surface was superficially ulcerated in patches or excoriated; it was of considerable inconvenience to the patient, but gave him no pain. (See engravings.)

After being under treatment for four weeks the patient's condition improved, the cough ceased, and the ulcerated

surfaces healed; the suppurations in the cellular tissue about the body had dried up, and he had gained flesh. On April 12th the tumour was removed under ether. In order to meet the expected hæmorrhage an iron clamp covered with leather was used, having been specially made by a local ironmonger for the case. It consisted of two long pieces of iron curved on the edge and fastened at pleasure at the two ends by two screws and nuts. The pedicle having been secured by the clamp close to the iliac crest, the tumour was amputated, and as many vessels as could be seen were tied. After this the clamp was a little relaxed, when many more vessels, seen by the spouting of blood, were secured, and the clamp was then removed. Considering the enormous number of vessels, very little hæmorrhage occurred, as the clamp proved most valuable. The lips of the wound were drawn together with silver wire and fishing gut, and the dressing consisted of a large wood-wool pad. On April 20th the drainage tubes were removed. A little suppuration had occurred here and there, but the wound was quite healthy. On April 30th the wound was almost entirely healed, and on measurement was found to extend to fourteen inches. On May 12th the patient went to the convalescent hospital at Silloth.

My thanks are due to our excellent house-surgeon, Mr. G. F. Smith, who was with us at that time, not only for the notes of the case, but also for the care he took in getting the clamp fitted. The patient was shown at the Carlisle Medical Society on Jan. 13th of this year. The wound had remained sound, and little or no deformity was visible, except the linear scar. The man was better able to do his work, but his intellectual deficiency was unaltered. The tumour weighed 6 lb., and has been placed in the Hunterian Museum of the Royal College of Surgeons (No. 373 C.). In structure it was soft and somewhat pulpy, though firm, and under the microscope was seen to consist of white fibrous tissue with spindle-shaped, oval, and round cells, with here and there some glandular tissue; there was, however, no evidence of any morbid activity of the sebaceous glands.

After the patient left the hospital I made some inquiries concerning his mental defect, and was told by his employer that he would do what he was told and was ordinarily useful, but would never make a skilled workman, as he had no ideas. I mention this because Hilton Fagge (vol. ii., page 745) draws attention to Hebra's remark that when molluscum tumours are numerous there is deficiency in mind and body. The engravings were made by Danielsson from photographs, and show the large tumour very well; but many of the small tumours were too minute to delineate, therefore only larger ones are represented.

Carlisle.

REMARKS ON THE

ACCIDENTS WHICH NOT INFREQUENTLY OCCUR TO PARTURIENT WOMEN.[1]

BY WILLIAM DUNCAN, M.D., F.R.C.S.,

ASSISTANT OBSTETRIC PHYSICIAN AND LECTURER AT THE MIDDLESEX HOSPITAL.

THE accidents of parturition on which I propose to make some remarks are—(*a*) laceration of the cervix uteri; (*b*) laceration of the vagina; (*c*) laceration of the perineum; (*d*) post-partum hæmorrhage. When we consider the wide extent of ground covered by these subjects, it is obviously impossible for me, in the short time at my disposal, to enter into them very fully; nor, indeed, is it necessary, in order to attain my object, that I attempt to do more than put forward the main points; but I wish to lay special stress on some, the importance of which, it appears to me, are not sufficiently recognised or appreciated.

1. *Laceration of the cervix uteri.*—This accident is one of the most frequent that occurs during parturition. Indeed, most likely some slight tearing takes place in almost every case, but this kind (as it speedily heals) is of no importance, except that it may, unless antiseptic midwifery is carefully practised, be the path by which septic material becomes absorbed, and either pelvic cellulitis or puerperal septicæmia be set up. Lacerations, on the other hand, which extend through a great part of the infra-vaginal cervix, or even up to the vaginal reflexion, have, in addition to the danger of septic absorption, both immediate and remote effects of great importance, which are far too frequently ignored, and even denied, by some experienced gynæcologists, but which I confidently assert from personal observation to be potential factors in the causation of puerperal and chronic uterine disease. Opinions differ as to the frequency with which these deep lacerations occur, and when occurring cause uterine disease; for there is no doubt that an extensive laceration sometimes exists in women who are apparently in perfect health. Emmet[2] says that 32·80 per cent. of all women under his observation who had been impregnated and had suffered from some form of uterine disease were found to have laceration of the cervix. Pallen[3] asserts that the condition exists in 40 per cent. of women with uterine disease. Goodell[4] states that about one in every six women with uterine disease has an ununited laceration of the cervix; whilst Mundé[5] found on examining 2500 parous women that 25 per cent. had well-marked laceration, but that only about 11 per cent. showed symptoms and required treatment. My own investigations have shown me that about 27 per cent. of all the mothers I examined had decided laceration, and about 6·5 per cent. required local treatment.

It is evident, therefore, that whilst this lesion occurs frequently during childbirth, only a comparatively small proportion of all the cases is sufficiently important from a pathological point of view to merit recognition as causing uterine disease; the proportion is, however, more than sufficient to call for our careful attention as to its preventive and curative treatment.

The causation of these lacerations is much disputed; some consider they occur more frequently when rapid dilatation of the cervix takes place, others that the opposite condition (tedious labour with rigid cervix) is the chief cause, and this certainly was stated to be the kind of labour in the great majority of the cases of extensive laceration which have come under my notice. Two other causes must be noted:—(1) that pernicious kind of meddlesome midwifery where an attempt is made to hasten the dilatation of a somewhat rigid cervix by sweeping one or two fingers rapidly round its inner surface, at the same time endeavouring to push the cervix over the head; and (2) the application of the forceps before full dilatation has taken place, and then the speedy delivery of the child. No doubt it is very tempting to one who is an adept in the use of the forceps, especially if he be overworked, to have recourse to a proceeding which will soon set free both his patient and himself; but I feel sure if he will make a careful digital examination about a fortnight later (as I maintain should be the invariable practice of every obstetrician), he will find a much larger percentage of torn cervices amongst those cases where, with the above mentioned condition, he has used the forceps than in those where he has administered some chloral or chloroform. On the other hand, I quite agree with Mundè[6] when he says "an experienced operator, by gently and gradually evolving the head and regulating its progress with the forceps, may even prevent a rupture both of the cervix and perineum." Now, whilst it is generally admitted that very few women are confined at term without sustaining some laceration of the cervix, there is great difference of opinion as to what percentage (if any) require operative interference later on. Dr. J. Henry Bennet,[7] in a paper read before the International Medical Congress in 1881 said "he thought the operation a totally unnecessary one, unless in some extreme exceptional case." This view is also held by some gynæcologists of experience, to whose opinions much weight should be attached. On the other hand, I am bound to say that the opposition to trachelorraphy is, as far as I know, limited to those who have never yet performed the operation, whereas it is viewed more or less enthusiastically by those who have practical experience of it. In the discussion which ensued on Dr. Bennet's paper there was an unanimity of opinion as to its value in suitable cases; and I think we are much indebted to Dr. Playfair[8] for being the first in this country to bring the subject in all its bearings into notice. Having performed the operation twenty-seven times, I can speak confidently as to the immense relief it affords in the vast majority of cases. I would here point out the great value of Sim's speculum, not only in the diagnosis of laceration of the cervix, but also in many other uterine diseases. Indeed, the ordinary tubular or Ferguson's speculum is worse than useless in those cases where laceration with ectropion exists, as it rolls in the everted edges of the torn lips, and thus the appearance resembles an ordinary (so-called) hypertrophy of the os." For the last few years I have discarded it altogether, except to demonstrate to my class the totally dissimilar and deceptive appearances seen on looking through it at well-marked cases of laceration, compared to those found on using the duck-bill, gently passing down the uterus with a vulsellum forceps, and then [illegible] the torn edges with a pair of tenacula.

The *immediate* results of a laceration may be either [illegible] or septic absorption. Cases of post-partum [illegible] occasionally occur where the uterus feels well [illegible] must then necessarily be due to [illegible] either of the cervix or some other part of the [illegible]. It is, unhappily, of not very uncommon [illegible] a woman's temperature, within a few days after [illegible] runs up with the usual febrile symptoms and pain in the lower abdomen or pelvis. On examination we find a cellulitic exudation in one or other broad [illegible] which either becomes absorbed after a time, leaving more or less permanent injury in the shape of flexions, adhesions, &c., or it goes on to suppuration. In other (and fortunately rarer) cases puerperal septicæmia, with all its accompanying grave dangers, sets in. Now, on examining a puerpera, in whom inflammatory symptoms have supervened, there will be found present (almost invariably) lacerations either of the cervix, vagina, vulva, or perineum; and these lesions, when carefully inspected, will be seen to have a sloughy appearance. Steurer,[9] on investigating an epidemic of puerperal fever at Strasburg, found diphtheritic patches on the vulva, and from these traced bacteria into the connective-tissue spaces, where their presence gave rise to cellulitis. From the spaces they entered the lymphatics, causing lymphangitis.

The *remote* effects of laceration depend on the extent of the injury: they may be *nil*, or we may have any of the following—namely, subinvolution going on to areolar hyperplasia of the cervix or whole uterus (so called chronic metritis), endometritis, cystic degeneration of the cervix, uterine displacements, chronic pelvic peritonitis and cellulitis, chronic ovaritis, sterility or abortion, and, lastly, it is said to predispose to epithelioma—a truly formidable list.

It is curious, as Mundé observes, that sterility and abortion should result from the same pathological process; but it is, nevertheless, true in some instances. One of my cases was a most interesting example of repeated miscarriages resulting from laceration of the cervix. The patient had had seven miscarriages (all at about the same date) since her confinement six years previously. There was no sign or history of syphilis, and no uterine displacement, but there was a deep laceration, reaching up to the vaginal roof, with much hypertrophy and eversion of the cervix, and this condition appeared to me to be the *fons et origo mali*. Her subsequent history proved the correctness of the diagnosis; for, three months after I had successfully performed Emmet's operation, she again conceived, and this time went on to term, and was safely delivered without relaceration of the united cervix.

Treatment.—The preventive treatment consists in the judicious use of opium, chloral, or chloroform, in the avoidance of all manipulative efforts to dilate the cervix with the fingers, or attempts to apply the forceps and effect delivery before complete dilatation has taken place. When a laceration occurs, it has been recommended by Pallen of New York to have recourse to immediate suture. Having failed to check by a tampon post-partum hæmorrhage from a lacerated cervix, he passed Sim's speculum, sewed up the laceration with silver wire, and thus stopped the bleeding. For my own part, in a case of that kind, I should first try hot water injections, and if these failed then operate, using all precautions possible to avoid septic trouble. If, however, there be no hæmorrhage, it seems to me better not to attempt immediate suturing, as many lacerations which appear deceptively large just after parturition become much smaller and of no consequence (or even completely unite) if the patient be kept strictly quiet for three or four weeks, and have a hot vaginal douche used night and morning. Here we see the importance of making a vaginal examination before ceasing our attendance, in order to satisfy ourselves that no laceration of any moment exists. It is obviously beyond the scope of this paper to enter into the treatment of old laceration of the cervix or of the conditions it may give rise to.

2. *Laceration of the vagina* may be of two kinds: superficial and deep. (*a*) *Superficial* lacerations occur very frequently, and are, as a rule, mere denudations of the mucous membrane, by the passage of the head. They afford facilities for the entrance of septic germs into the system, as seen by Steurer's researches, before alluded to. Their treatment consists in the antiseptic management of the puerperal state, as will be discussed later. (*b*) *Deep* lacerations may occur at any part of the vagina, but they take place most commonly at the lowest part in the structures which form the pelvic floor; they are very important from their ulterior consequences, and special attention has been drawn to them by Emmet of New York[10] and Schatz of Rostock.[11] Emmet considers the lesion to be a separation and tearing of the connective tissue and fascia of the pelvic floor. He says: "Under certain circumstances, in childbirth, the soft parts of the vagina are crowded up in advance, as the head passes along the floor of the pelvis. Laceration, if it occurs, does not take place in the posterior commissure of

[illegible]

Digitized by Google

the labia majora, but somewhere within the canal, and it is only as the shoulders escape that the rent is completed externally. The soft parts may be lacerated or not, but in many instances, before they are torn, I believe the fascia extending from the sulcus on each side becomes separated from its connexion with the vaginal outlet, and thus separation may take place without any external injury. We have then the condition I have compared to the mouth of a bag with a running string." Schatz says, "Hitherto neither the frequency nor the clinical significance of lacerations of the muscles of the pelvic floor has been sufficiently appreciated. In their connexions with displacements of the pelvic organs, and especially with prolapse, they are quite as important as, if not more important than, laceration of the perineum." The result of these lacerations is, as Schatz observes, that we not infrequently see cases of rectocele, cystocele, and prolapsus uteri, *where there is a fairly good perineum*, so that this structure, although it undoubtedly forms a small but strong part of the sacral segment of the pelvic floor, and thus aids in maintaining the pelvic organs in position, does not constitute, as was formerly supposed, the "keystone of the arch." My attention was specially drawn to these lacerations of the pelvic floor by Dr. Emmet, whom I have seen perform, in the New York Women's Hospital, his plastic operation on the posterior vaginal wall for their cure, and I have since then several times similarly operated, with great relief to the patients. With regard to immediate treatment (as these lacerations are usually associated with more or less tearing of the perineum), it becomes, as Emmet points out, even more important to operate immediately than it would be if the perineum were alone implicated. By closing a lacerated perineum just after delivery, if it be a superficial rent, the operation of itself would be of little importance, beyond lessening the danger from blood poisoning; but it gives the opportunity for the introduction of deep sutures, which may again bring together the separated muscular fibres of the vagina.

(To be concluded.)

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. THOMAS'S HOSPITAL.

TWO CASES OF PAPILLOMA OF THE BLADDER REMOVED BY THE WIRE ÉCRASEUR—IN ONE (MALE) BY SUPRAPUBIC CYSTOTOMY, IN THE OTHER (FEMALE) BY THE URETHRA; CURE.

(Under the care of Mr. SYDNEY JONES.)

THESE cases are good examples of the clinical history of vesical tumours of a simple kind, in which hæmorrhage of a definite character has been the most marked symptom. From the sex of the second patient an attempt was made (and successfully) to remove the tumour through the urethra rather than after suprapubic cystotomy, although it was of considerable size for passage along that canal. In each the growth was attached by a well-defined pedicle, and its simple character and complete removal will probably render the success of the treatment permanent. We are indebted for the following notes to Mr. Cecil W. Cooke.

CASE 1.—W. B——, male, aged fifty-four, a blacksmith, was admitted on March 21st, 1887, having previously been under the care of Dr. Phillips of Tickill, near Rotherham. Two years previously to admission he first began to pass blood occasionally with his urine. The attacks of bleeding used to last from four to six weeks, and would then pass off for about the same length of time. The intervals between these attacks have been gradually diminishing, and for the last six months he has always passed blood in his urine. The blood was generally mixed with the urine, but sometimes came afterwards, and sometimes there were clots, the passage of which caused pain. Otherwise there appeared to have been little or no pain in connexion with the symptoms. There was some increased frequency of micturition. During the last three months he had been losing flesh, was looking very anæmic, and getting much weaker.

On admission no calculus could be detected by the sound; something soft might be felt projecting from the right side of his bladder; microscopical examination showed some grouped cell growth. It was evident that the symptoms complained of by the patient were dependent on the presence of tumour. The patient was a stout man, with a deep perineum, and it was certain that an attempt at removal of any tumour would be much more difficult and unsatisfactory by the perineum than by a suprapubic cystotomy. An exploration through the perineum was not thought necessary or desirable, so that it was determined to perform at once a suprapubic operation. This was done by Mr. Sydney Jones on March 30th. Into the bladder ten ounces of boracic solution were injected; and into the rectum was inserted an oval indiarubber bag, which was distended with sixteen ounces of water. These injections were retained under the ordinary method. There was no difficulty in exposing the bladder uncovered by the peritoneum, nor was there any hæmorrhage worth notice. A vertical incision was made into the bladder; this incision enabled one easily to pass the forefinger, by which the interior of the bladder was explored. A fimbriated papillomatous tumour about the size of a walnut was at once discovered on the right side of the bladder, about, but rather above and in front of, the situation of the right ureter. The loop of a wire écraseur was carefully placed around the attachment of the tumour, and, fixed there by the left forefinger, was tightened by screwing with the right hand until the tumour fell off and was removed. The removal was found to be effected flush with the surface of the mucous membrane; and there was comparatively little hæmorrhage. The bladder was well washed out with boracic lotion. The upper part of the abdominal wound was brought together by sutures. The bladder was not sutured, but a large drainage-tube inserted. No catheter was inserted in the urethra. The wound was lightly covered with iodoform gauze.

March 31st.—A little tenderness about the abdomen made one think it desirable to remove the stitches.

April 4th.—The patient has been going on very well since the above note, and has had little or no pain. The bladder has been washed out with boracic lotion every day. The temperature has varied from normal to 101·6°.

9th.—During the last two or three days the patient has been passing a little urine by the urethra. The wound looks quite healthy, and his condition is improving.

18th.—Amount of urine increasing through the urethra, less through the wound.

23rd.—The patient improves steadily. Wound filling up; edges brought into closer apposition by strapping.

May 4th.—Since May 1st (about one month after the operation) the man has passed all his urine by the urethra; wound almost filled up.

10th.—The patient got up to-day. Wound now quite healed, and the man is well in every way. The anæmic condition, which was so evident on his admission, is quite recovered from. He left the hospital quite well a few days later.

The specimen is now in St. Thomas's Hospital Museum. It was examined by Mr. Shattock, and its structure was pronounced to be simple papilloma.

CASE 2.—F. M.——widow, aged fifty-eight, was admitted on May 23rd, 1887. About six years previously she first began to pass blood with her urine. At that time it continued for two or three days, and she saw no more of it for three or four months. The attacks of hæmorrhage have more and more frequently occurred; and on May 13th, ten days before her admission, she had a pretty severe and continuous attack, for which she consulted a doctor, who sent her into the hospital. Whenever she passed blood she suffered pain, but not at other times, and when clots were present she had frequency of micturition, amounting almost to a state of incontinency. The medical man whom she consulted, and who sent her into the hospital, sounded her and said she had a "tumour."

When admitted, the woman said that she had continuous

Digitized by Google

pain, much worse when passing urine, not worse when moving about; that it was worse when the bladder had been emptied. However, on examination she seemed to have incontinence; there was continuous trickling from the urethra of slimy blood-stained urine. On May 28th Mr. Sydney Jones examined with a sound. There was no calculus, but there was a sensation of thickening in the posterior wall of the bladder. Microscopical examination of the urine showed blood-corpuscles, pus-cells, crystals of triple phosphate, amorphous phosphates, but no cell growth enabling one to arrive at a diagnosis of tumour.

On June 3rd the patient was put under ether; the urethra was dilated, and the bladder explored by the forefinger. A tumour was then felt, cauliflower-like, floating in the bladder, about the size of a Tangerine orange, and attached by a pedicle about half or three-quarters of an inch in length to the floor of the bladder, about an inch behind the vesical orifice of the urethra. The pedicle could be distinctly felt, and gave one the impression of being the thickness at least of an ordinary goose quill.

On June 8th the patient being again put under ether, Mr. Sydney Jones operated. The forefinger was passed through the dilated urethra into the bladder so as to feel the pedicle. A catch forceps was then passed into the bladder so as to secure the pedicle below the forefinger. The pedicle and tumour were then drawn forwards, and the noose of a wire écraseur was passed over the tumour and forceps, and a few turns of the screw readily detached the tumour. There was no hæmorrhage from the divided pedicle. The size of the removed tumour was less than when examined with its normal distension and vascularity. When removed it was the size of a walnut, and in water presented a beautifully villous character. Mr. Shattock, who described it as a charming specimen, looks upon it as simple papilloma. The specimen is in St. Thomas's Museum. The bladder was washed out well with boracic lotion, and a large-sized catheter was left for some hours in the urethra.

There is nothing to record in connexion with the after symptoms. The patient went on continuously well. Only on the night of the operation did her temperature reach 100°; afterwards it was normal. She left the hospital on June 27th, nineteen days after the second dilatation of the urethra and the removal of the tumour. On her discharge from the hospital there was no incontinence, no blood in the urine, and no pain.

The patient was again seen on July 4th, and was in excellent health.

Remarks by MR. SYDNEY JONES.—The above cases are of interest in that both presented the characteristic symptom, in the first place, of hæmorrhage without any additional symptom. In the first case there was in the later stages some frequency of micturition, but pain only during the passage of clots. He was rapidly going to the bad from loss of blood. In the second case, that of the woman, there was at first hæmorrhage; later on pain and incontinence, probably due to the attachment of the tumour, the pedicle of which was placed only a short distance behind the vesical orifice of the urethra, so allowing the tumour to be washed forwards and to obstruct the exit of urine. In the first case there could be no doubt of the existence of tumour. It was certainly the course to pursue to do a suprapubic cystotomy at once, without any preliminary perineal operation; and in any similar case I should at once follow the same course. The suprapubic operation enables one to expose the tumour in the best manner possible, and to use those means best adapted for its perfect removal. The bladder, too, is easily explored for any other growth. I do not consider, with the peritoneum well out of the way, and with free drainage subsequently provided for, that the suprapubic operation is a serious one. For tumours, I think, the suprapubic operation is the one to be selected. For stone, in my opinion, this operation should be selected for large calculi. The same objection exists against operating for vesical tumours through the perineum as for stone. In the case of the male above referred to, one month was occupied for the healing of the suprapubic wound. Suppose the operation had been done through the perineum, not less time in healing would have been occupied, and one would have had more difficulty in exploring and thoroughly removing the tumour. In the case of the woman, the tumour was so easily accessible through the dilated urethra, that no better operation could be suggested than that which was carried out.

SAMARITAN HOSPITAL FOR WOMEN, NOTTINGHAM.

A CASE OF NEPHRECTOMY FOR HYDRONEPHROSIS; REMARKS.

(Under the care of Dr. ELDER.)

A. S——, aged twenty-three years, single, was admitted on April 9th with a well-marked abdominal swelling on the right side. The following history was elicited. It is now seven years ago since first an aching pain in the right side, not constant but intermittent, was experienced by the patient. Machining, which occasionally had to be done in her occupation of dressmaking, or any unwonted and severe exertion, caused this discomfort, and its relief always followed resting. For several months this state of matters went on without affecting her general health, when suddenly and spontaneously it ceased and caused no further trouble for the space of three years and a half. Then an attack similar to the present came on and a "lump" on the right side now was recognisable. After a duration of three months this swelling disappeared as suddenly as it came. It had caused no particular symptom, but merely a sense of prostration. Again, six weeks prior to admission, the tumour rapidly reappeared, accompanied this time by pain, sickness, and slight constitutional disturbance. During this last invasion the patient has lost flesh, but otherwise her health is unaffected. When walking, standing, or lying on the left side a dragging, sickening sensation is complained of. There has never been hæmaturia or other unhealthy condition of the urine, and menstruation has been uniformly normal.

The objective signs were as follows: On the right side there was an irregularly-rounded, prominent swelling, insensitive and fluctuant, which when the patient lay on her back naturally fell into the right renal position, but which was freely movable, either by changes of recumbency on the part of the patient or in obedience to manipulation. It pretty well filled up the space between the ileum and the lower border of the liver. Evidently overlapped in front by the ascending colon, as manifested by the percussion note, in other parts it was quite dull. No pelvic or hepatic connexion could be made out, so the diagnosis lay between a floating kidney which had become hydronephrotic, or renal hydatids—the former being looked upon as the most probable one. The urinary secretion was plentiful, normal, and with a 2·4 percentage of urea.

On April 13th the tumour was aspirated behind the peritoneal reflexion and eighteen ounces of straw-coloured fluid withdrawn. This had a specific gravity of 1004, was very slightly albuminous, contained no hooklets, but showed a few crystals resembling urea nitrate. Within a few hours the swelling was as large as before and caused pain; so taking into account that renal extirpation in a patient otherwise healthy, and with the other kidney sound and able to perform the necessary compensatory function, is not so much more serious than a nephrotomy, this operation was decided upon and carried out on April 19th by the lumbar method. The comparative absence of peri-renal fat was noted at the time. The after progress of the case was one of uneventful progress towards recovery, the temperature only rising to 99° F. once, and this on the advent of a menstrual period. The patient left the hospital on June 5th with part of the wound not quite healed. The specimen removed showed the cyst to be composed of the upper part of the ureter and the pelvis and calices of the kidney, of which the greater part of the secreting tissue had become absorbed.

Remarks by Dr. ELDER.—The history of the above case points pretty clearly to its being an instance of a movable kidney becoming cystic owing to interference with the urinary flow, by reason of kinking and impermeability of the ureter. Intermittent hydronephrosis is thus explained—a condition which usually becomes permanent by virtue of the structural changes which take place in the walls of the ureter from the alternations of extreme tension and evacuation. This doubtless happened in my own case, thus explaining the repeated suddenness of the onset and disappearance of the swellings. Calculous impaction of the ureter, pressure from without by ovarian or malignant tumours, and bands of cicatricial tissue in the pelvis, are well-recognised causes of this pathological condition.

With regard to the treatment of these cases, allow me to draw attention to a few statistics from Gross's monograph on Nephrectomy, published in 1885, and which includes all the cases of extirpation and allied operations obtainable from public and private sources up to date. Of six cases of aspiration, three were cured, two improved, and one died from some cause unconnected with the operation. Five cases were injected with tincture of iodine, of whom two were cured and three died. Of fifteen cases of puncture, twelve died, one was cured, and two had temporary relief. Incision with drainage in twenty-five cases cured twenty-one, and there were four deaths. Of these the mortality was most by the ventral operation. Of the twenty survivors (for some reason one is left out by the author), eleven have urinary fistula, of whom two have been relieved of this discomfort by a nephrectomy. Extirpation has been performed twenty-one times, with a total mortality of 38·09 per cent. Ten deaths were recorded out of seventeen ventral operations, and one of four lumbar. Gross, as the result of these investigations, recommends in the first instance aspiration of hydronephrotic tumours, then, if necessary, incision and drainage, in preference to the more serious operation of removal of the organ. It seems to me that, failing a cure by aspiration, a lumbar nephrectomy, in an otherwise good and young subject, is very little more dangerous than a nephrotomy, and is not followed by all the unpleasantness of a primary fistula, which, as we have seen, follows the majority of cases of incision and drainage. The present makes my fifth nephrectomy, with one death—the remaining three, previously reported in the pages of this journal, being in good health.

WOLVERHAMPTON GENERAL HOSPITAL.

ANEURYSM OF CORONARY ARTERY; RUPTURE; NECROPSY; REMARKS.

(Under the care of Dr. MALET.)

FOR the following notes we are indebted to Mr. Arnold Evans, house-physician.

J. D——, aged five, was admitted on Jan. 29th, 1887. He was a pale, emaciated, and feeble child, with scarcely sufficient strength to walk; he had three small unhealthy-looking sores, two on the face and one on the leg. His father, who brought him, said that for three weeks the child had suffered intensely from thirst and copious diuresis, the former being so distressing that he would even drink dirty water from puddle-holes in the road. Enormous quantities of urine were passed after admission, and a specimen examined was pale and clear; it had a specific gravity of 1002, and contained neither sugar nor albumen. The thoracic organs were examined, but nothing abnormal detected. When attempting to sit up in bed on the morning of Feb. 1st he complained of pain in the chest, then fell back and died almost instantaneously.

At the post-mortem examination the pericardium was distended with about five ounces of clotted blood, adherent to the walls of the heart. The ventricles were contracted and empty; valves competent and healthy. On removing the clots, a softened spot, surrounded by ecchymosis, was discovered in that part of the wall of the left ventricle which is overlapped by the appendix of the left auricle, the auricular appendix itself being discoloured externally, but its internal surface quite healthy. A probe passed along the left coronary artery from the aorta appeared at this softened point, and on dissecting out the artery it was found that its lumen at the above-mentioned point was increased and its walls attenuated, the aneurysmal dilatation thus formed being about the size of a pea. It was clearly from a rupture of this aneurysm that the hæmorrhage had occurred.

Remarks by Mr. EVANS.—Attention having been called to hæmo-pericardium in a recent issue of THE LANCET by Mr. J. W. Batterham, I have been induced to report the above case. Although hæmorrhage into the pericardium is of frequent occurrence from a variety of causes, it rarely happens that rupture of an aneurysm of the coronary artery occasions it. I have been able to find records of nine similar cases, a *résumé* of most of which by Dr. Crisp will be found in the twenty-second volume of the Transactions of the Pathological Society; in most of these cases, however, the subjects had reached an advanced age, and the chief interest of the case just recorded is centred in the age of the patient.

Medical Societies.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

An Improved System of Flush Closets for Small House Property.—The Powers and Responsibilities of Local Authorities in regard to Rabies.

A MEETING of this Society was held at the Scottish Corporation Hall, Crane-court, Fleet-street, on Friday, May 20th, Dr. Alfred Hill, President, in the chair.

The Council presented the following report, which was adopted:—1. That the annual meeting be held at a date shortly preceding the October meeting, so as to enable the proposed amalgamation of the various societies to be completed and the officers for the ensuing session chosen from the reconstituted society. 2. That the dairies, cowsheds, and milkshops regulations as amended be issued.

The PRESIDENT referred to the loss the Society had sustained by the death of Dr. Iliff, and it was unanimously resolved that a letter of condolence be sent to the bereaved family.

The PRESIDENT read a paper on an Improved System of Flush Closets for Small House Property. After referring to the different methods of excremental refuse disposal and the disadvantages attending each, Dr. Hill explained his method by which slop water was utilised, which, being of higher temperature than water supplied by the mains, prevented pipes from freezing. The amount of water thus made available he estimated at fifteen gallons per day in a small house, or 150 gallons for a court or row of ten houses, a larger amount than is used in connexion with an ordinary closet supplied from a cistern. Slop water and surface water are conveyed to a tank which is constructed in two chambers, the first to arrest earthy and other solid matters, the second to constitute an automatic flushing tank, which, however, is only necessary in cases of one or two houses in which the quantity of water might prove insufficient. From this second tank the water is discharged into a horizontal glazed pipe, twelve by ten inches in diameter, in connexion with the sewer from which it is disconnected by a syphon trap, to which access is given by means of a man-hole. The closets are placed over this pipe, and beneath each seat is a perpendicular salt-glazed stoneware pipe connected with that below; the upper aperture of the perpendicular pipe is about seventeen by fifteen inches in its diameter, the lower twelve by ten inches. At the junction of the two the lower opening is received into a collar; the vertical pipe is so shaped that its posterior wall is perfectly vertical, while its anterior wall towards the lower end inclines in a straight line backwards and downwards, causing a narrowing of the lower aperture, to enable it to enter the collar or flange of the horizontal pipe; the latter is ventilated by a separate vertical pipe connected with it and running up the side of the house in a suitable position. Dr. Hill stated that this arrangement had the advantages of cleanliness and cheapness, and was being largely adopted in Birmingham.

Dr. WHITELEGGE, medical officer of health for Nottingham, read a paper on the Powers and Responsibilities of Local Authorities in regard to Rabies. In the first part of the paper the questions which present themselves to a local authority in considering its action in regard to rabies were examined from the point of view of the medical officer of health. These questions were stated thus:—1. Is rabies likely to become prevalent in the district? 2. By what means is it liable to be introduced and maintained? 3. What evidence is there of the utility of the preventive measures authorised by the Rabies Order of 1887, and the Dogs Act—viz., compulsory muffling and the slaughter of stray dogs? 4. What form should such regulations take? As bearing upon the first question, it was shown that before the number of known cases was such as to excite alarm, the disease must be already widely spread. Rabies could be detected with certainty, both by its symptoms and by the evidence attainable after death, but the great majority of cases doubtless occurred among vagrant dogs and other animals never coming under observation; and, apart from the fact that even the most characteristic symptoms were frequently overlooked by the owners of dogs, it was common for an affected animal to wander away from home in the earliest stage of the disease. The second question was answered by pointing out that the bite

Digitized by Google

of a rabid animal was beyond doubt the cause of many cases, and could scarcely ever be logically excluded, even if not proved. The alternative theory of origin *de novo*, or even origin otherwise than from a previous case of rabies, was shown to be unsupported by evidence, and indeed opposed to the experience of other countries. The history of rabies in Sweden, Malta, Mauritius, Réunion, and South Africa proved that cases did not arise apart from the introduction of rabid animals. Thirdly, a brief account was given of the complete success of preventive measures in Sweden and Réunion, and of the immense reduction in deaths from hydrophobia in less isolated countries, such as Prussia, which had adopted the same measure. The statistics of Berlin and London were taken as examples of the suppression of rabies in large cities by such means. Finally, it was urged that the regulations, both for muzzling and for the slaughter of stray dogs, should be stringent and rigidly carried out for a sufficient length of time. As regards the advice to be given to a person bitten by a rabid animal, it was premature as yet to pronounce any final opinion upon M. Pasteur's procedure, but for present purposes the problem might be regarded as an alternative between accepting his treatment, and thus joining those of whom 2½ per cent. die with or without the horrible symptoms of ordinary hydrophobia, or rejecting the treatment and sharing the risk of those of whom not less than 16 per cent. die of hydrophobia. In many instances it was essential to determine with certainty the existence or non-existence of rabies in a given animal, where this could only be done by experimental inoculation. Not only was this forbidden by law as regards ordinary individuals, but there was in England no official institution to which application could be made, and it therefore became necessary to appeal to the charity of the Brown Institution. The history of rabies in Nottingham and the adjacent rural districts during the years 1885-6-7 was then referred to at some length, and the results of the application of muzzling regulations in the borough shown to be confirmatory of their value. A temporary suspension of muzzling led to a considerable increase in the number of known cases of rabies, followed by a rapid reduction upon the re-enforcement of the regulations. Statistical and other details were given of the fifty-nine reported cases of rabies. The means adopted for sending patients to M. Pasteur were described, and also the precautions necessary in order to obtain experimental verification of the diagnosis of rabies in cases of doubt. The spinal cords of seven presumably rabid animals had been forwarded to Professor Horsley for examination, with an affirmative result in every instance. Nine patients from the Nottingham district had undergone Pasteurian treatment, and all of these remained in good health. The only case of hydrophobia was that of a man who was bitten by a strange dog four months previously, during the abeyance of the muzzling regulations. In conclusion, it was pointed out that rabies could not be permanently stamped out except by the co-operation of neighbouring districts, and that in an island such as this only a determined effort was needed in order to banish for ever rabies and hydrophobia.

CAMBRIDGE MEDICAL SOCIETY.

AT the meeting on May 6th, the following communications were made:—

Abscess between the Spleen and Diaphragm, with Secondary Pyæmic Abscesses in the Liver.—Mr. M. GRIFFITHS read the notes of this case, a woman, aged twenty-two, single, who had been admitted into Addenbrooke's Hospital, under Dr. Bradbury, on Feb. 23rd last. Her father, mother, and one sister died in decline. She suffered occasionally from dyspepsia, but was fairly well till February 1st, when she had pain behind the sternum, but improved under medical attendance until Feb. 19th, when she had frontal headache and shivers; no cough. On admission, she was pale, and complained of pain in the left shoulder, loss of appetite, and weakness. The physical signs pointed to commencing consolidation at the apex of the right lung, and there was a friction sound with the heart. The temperature was 102·2° morning, 105·6° evening. Pulse 120. The urine contained some albumen. For the next few days she had much pain behind the sternum and an attack of dyspnœa, and on March 8th some dulness was noticed at the base of the left lung with bronchial breathing. The temperature was partially controlled for a day or two with antipyrin. But diarrhœa and great prostration came on, and she died on March 18th.

The necropsy revealed a large abscess, containing a pint of thick pus, situated between the diaphragm and the diaphragmatic surface of the spleen. The walls of the abscess were formed by the diaphragm and the capsule of the spleen. The splenic pulp was soft and diffluent. The heart was healthy; the kidneys slightly enlarged. There were a few recent adhesions over the front of the left lung, and collapse and pneumonic consolidation at the bases of both lungs, the left being firmly adherent to the diaphragm. The liver contained numerous small pyæmic abscesses.

On the Accidents which not infrequently occur to Parturient Women.—Dr. WILLIAM DUNCAN'S paper on this subject is published on another page.

Early Decidua from the Human Uterus.—Mr. WHERRY exhibited a complete decidual cast of the uterus and Fallopian tubal extremities. There was no ovum, nor spot where the ovum might have lodged. It came from a young, childless, married woman, with the following history: A year previously she had some menorrhagia and pain in the body, which was thought to be gall-stones. She recovered and was well and regular in her periods during twelve or thirteen months, when she missed two periods. She then rode twenty miles on a tricycle in one afternoon. This performance was followed in a few hours by a violent attack of vomiting and abdominal pain. All the signs of peritonitis appeared; then subsided in ten days, leaving some fluid in the abdominal cavity; menstruation then began and the decidual cast was expelled. She made a good recovery.

Reviews and Notices of Books.

The Student's Guide to Diseases of Children. By JAS. FREDK. GOODHART, M.D., F.R.C.P. Second Edition. Pp. 692. London: J. and A. Churchill.

Treatment of Disease in Children, including the Outlines of Diagnosis and the chief Pathological Differences between Children and Adults. By ANGEL MONEY, M.D., M.R.C.P. Pp. 560. London: H. K. Lewis.

Clinical Studies of Disease in Children. By EUSTACE SMITH, M.D., F.R.C.P. Second Edition. Pp. 318. London: J. and A. Churchill.

OF these three books, the first two go over the whole field of children's diseases, Dr. Angel Money mainly confining himself to treatment, Dr. Goodhart entering more fully on pathology and symptoms. Dr. Eustace Smith, after a general introduction on the peculiarities of the constitution of early life, and their modifying influence on disease, and after laying down rules for the clinical examination and treatment of children, devotes the rest of his book to the clinical aspects and pathology of certain diseases of the respiratory organs and of tuberculosis.

Dr. Goodhart's work, of which this is a second edition, gives in a short compass, a very clear and concise account of all the more important diseases of children, with their treatment. It is by no means a mere compilation, but contains the results of the author's own experience at the Evelina and Guy's Hospitals, and though intended as a student's manual, for which it is well adapted, it will be found equally useful by the practitioner who wishes to have in a small space the modern views on the pathology and treatment of children's diseases.

Of Dr. Money's work, which is essentially one on therapeutics, we can also speak highly. It gives a pretty complete exposition of the various methods of treatment which have been recommended by different authorities, and embodies the results of the author's experience at the Great Ormond-street Hospital. Avowedly with the intention of making his work as complete as possible, the author has introduced an unnecessary number of plans of treatment of a very dubious or even positively injurious nature; but his own recommendations are judicious and will meet with

Digitized by Google

general approval, and it is satisfactory to see how great is the general agreement on questions of treatment of all three authors.

On the important subject of the artificial feeding of infants both Dr. Goodhart and Dr. Money give very full directions, and are in the main in accord. The great advance which has been made in a scientific preparation of artificial foods has rendered the bringing up by hand a much easier task than it was formerly. They both give the formula for the preparation of the artificial human milk, and speak highly of it, as it well deserves; and if its use could be introduced among the poor we should have much less of the marasmus which forms so large a part of out-patient practice at children's hospitals. Dr. Money rightly regards the plan of preventing the clotting of the casein of cow's milk by the addition of large quantities of alkali, as lime-water, to be unscientific, and much prefers the mechanical effect of barley-water and other glutinous substances.

With regard to points about which there is still more or less conflict of opinion, we may observe that Dr. Goodhart considers that there is a membranous laryngitis which is not diphtheritic, basing his opinion rather on the authority of others than on his own observation and arguments, which, indeed, support the other view. It is somewhat remarkable that while a membranous pharyngitis is almost always regarded as diphtheritic, even though no asthenic symptoms should be present, a difference of perhaps less than an inch in the position of the false membrane is sufficient to change the opinion as to the nature of the disease. Dr. Goodhart considers that diphtheria is at first essentially a local disease of the fauces, and that the constitutional symptoms are due to absorption of the poison from the local focus. He accordingly recommends forcible detachment of the membrane whenever it forms, and thorough local treatment by solvents and disinfectants. Dr. Money, though generally agreeing in Dr. Goodhart's views as to the pathology of the disease, disapproves of forcible detachment and solvents. If the views of the latter writer should be generally adopted, the practitioner and the attendants will have a difficult task to perform, and the little patients a terrible amount of suffering to go through, not only from terror, but also from severe pain, as these diphtheritic throats are often extremely sensitive. It must, however, be remembered that by whatever channels the diphtheritic poison finds entrance, by the time the false membranes have appeared there is always already a general infection of the system, and that the patient's danger, unless the larynx be affected, is not due to a layer of false membrane on the mucous surfaces. Moreover, although it is quite right to disinfect the membrane by local applications as far as it can be done without causing serious distress, it is a very doubtful proceeding to exhaust the patient's strength by a battle every two hours; indeed, to carry out the treatment with any real efficiency, still more frequent applications should be made. Neither of the authors notices the great relief which is given by cocaine where swallowing is very painful; sometimes, indeed, this will enable a child, who had previously resisted all attempts to give food, to swallow with comparative ease. With regard to laryngeal diphtheria, Dr. Money recommends early tracheotomy; Dr. Goodhart thinks the operation should be delayed as long as possible. We certainly should be disposed to agree with the former. When once it is evident that false membrane is present in the larynx of a child, nothing is gained by delay. In the treatment of empyema Dr. Goodhart objects to the method, now so common, of excising a piece of rib as a matter of course; and both authors are opposed to the practice of washing out the chest. Dr. Eustace Smith, on the contrary, recommends washing out the chest daily if any fetor be present. We are disposed to agree with the first two authors in regarding the persistence of fetor as an indication that the opening is insufficient.

Dr. Goodhart regards the acute febrile form of infantile paralysis as due to a general inflammation of the spinal cord, which rapidly subsides, leaving here and there patches which have been shattered by the storm. Other cases he considers with Dr. Buzzard to be due to a peripheral neuritis, and analogous to Bell's palsy of the face. He considers chorea to be a functional cerebral disease and not caused by embolism. Dr. Money regards it in the same way, and ascribes it to scattered discharges of nerve energy usually proceeding from the cortical motor centres, probably the result of defective nutrition of the nerve cells. Dr. Goodhart rightly attaches great importance to rest in bed, and ascribes the improvement which so often follows admission into a hospital to this cause.

A hypercritical reader might object to a few expressions or statements in both works, of trifling importance, but which in books intended especially for students it would be better to avoid. Thus Dr. Money uses the word "teichopsia" (p. 416) in such a manner as might well lead an unwary student who was ignorant of Greek to suppose it meant coloured vision. Again, by a printer's error, we find *tâche* cérébrale, which means something very different from what is intended. Dr. Goodhart adopts the barbarous form "leukæmia" instead of leuchæmia. At page 540 Dr. Money gives the incubation period of German measles as about a week; Dr. Goodhart, more correctly, as a fortnight or more. Dr. Goodhart only mentions generally that the glands in the neck are commonly enlarged in this disease, but does not describe their situation—a point of great importance in the diagnosis. Dr. Money rightly mentions the post-cervical glands, but neither author describes the most characteristic of all—namely, the gland over the mastoid process. Surely it is a libel on so innocent an organism as the bacterium termo to ascribe to it, as Dr. Goodhart does, the infection of diphtheria.

Dr. Eustace Smith's book is the second edition of a work well and favourably known to the profession. The chief alterations are in the chapters on croupous pneumonia, pleurisy, and tuberculosis. Of especial interest are the chapters on catarrhal pneumonia and fibroid induration of the lung, which are, however, practically unaltered; and perhaps in the present state of our knowledge as to the pathology of tubercle it might be objected that many of the cases described as catarrhal pneumonia and fibroid phthisis were really chronic forms of tuberculosis. The author describes catarrhal pneumonia as resulting in caseous deposits, which may themselves soften down or give rise to secondary tuberculosis; but it is now generally recognised that if a caseous deposit causes tuberculosis it must itself be tubercular, and most pathologists would regard a caseous deposit in the lung which softened down and caused ulceration as almost certain to be tubercular in its nature. The absence of any examination for the tubercle bacillus necessarily leaves the nature of many of Dr. Smith's cases doubtful; for whatever view may be taken as to the causal relation between the bacillus and tubercle, it is impossible now to doubt that it is a constant element in tubercle, and its presence or absence decisive as to the nature of the process. Although in some few points the pathology of parts of Dr. Smith's work appears to us a little behind the time, this does not detract from its great clinical interest and value, and it may be confidently recommended to the profession as well worth perusal.

Hay Fever and Paroxysmal Sneezing: their Etiology and Treatment. With an Appendix on Rose Cold. By MORELL MACKENZIE, M.D. Lond., Consulting Physician to the Throat Hospital, and late Physician to the London Hospital. Fourth Edition. J. and A. Churchill. 1887.

DR. MORELL MACKENZIE very opportunely publishes a fourth edition of his book on Hay Fever, which must be regarded as one of the most complete expositions of our knowledge of this curious complaint in our language, and which indeed has found translators in other languages. It is not a little surprising that so busy a practitioner should

Digitized by Google

have found time to go so fully into the literature of this subject as Dr. Mackenzie has done. But it is not a case in which literature takes the place of experience, for both are *en évidence* in this book. The author shows, what is now indeed practically conceded on all hands, that hay fever depends in most cases essentially on pollen—though the particular pollen which gives rise to the disease in one case may not be the cause in another. Nor, indeed, is pollen always to blame. The late Dr. Flint had a peculiar exemption from all forms of asthma save when he slept in a strange bed, where the bed or pillows were of feathers; this was especially the case in inns and steamboats. In other persons the attacks are brought on by emanations from animals—as the horse, the rabbit, the cat, &c. But the hay fever class of cases is much the more numerous; indeed, so much so as to make them a special care to medical men. Dr. Mackenzie alleges that treatment is very useful, apart even from removal from the pollen-laden atmosphere, which is certainly the best course to advise. We must refer our readers for particulars to the book itself, but in the main he relies on soothing treatment locally, such as the application of cocaine, and on constitutional treatment which recognises the neurotic element in cases, especially the exhibition of the valerianate of zinc. In some instances, where there is hypertrophied tissue, more active local treatment is required, but the author does not regard coarse local disease as essential to hay fever, but rather as exceptional.

COLONIAL AND INTERNATIONAL CONGRESS ON INEBRIETY.

THE first Colonial and International Congress ever held on Inebriety and the Special Treatment and Legislation needed for the Diseased Inebriate took place at the Westminster Town-hall on the 6th inst., under the auspices of the Society for the Study of Inebriety.

The opening address was delivered by the President, Dr. Norman Kerr, who, after welcoming the members of the Congress, defined the disease of inebriety as a disease of the nervous system, allied to insanity, and characterised by an almost overpowering impulse to, or crave for, the oblivion of narcotism—a true intoxication mania, or, as he preferred to call it, narcomania. The disease assumed varied forms—periodic, constant, social, solitary. The form might be determined by complicating disease; thus there is the inebriety of insanity, of syphilis, of sunstroke, and of injury. The form might also correspond to the inebriant used—alcoholmania, opiomania, morphinomania, chloralomania, etheromania, chlorodynomania, and chloroformomania. Causes were predisposing and exciting. The chief predisposing causes were heredity, injudicious diet, bad hygienic conditions, sex, age, religion, climate, race, education, pecuniary circumstances, occupation, mental relations, temperament, &c. Of exciting causes some kind of nerve shock was the chief; others were accidents, disease, idleness and overwork, functional derangement, &c. The indications for sound treatment were (1) the unconditional withdrawal of the poison, immediate or gradual, according to its nature; (2) the removal, if possible, of the exciting cause; and (3) the reparation of the physical damage wrought by inebriety, the remedying of the pre-inebriate morbid condition and the strengthening of the moral control. After a warm tribute to American work for the inebriate, the president concluded by impressing on each member of the Congress the imperative duty of patience, of being content to inculcate a knowledge of the truth that many inebriates were diseased individuals and required medical and legal treatment in accordance with justice, and of hopefully looking forward to a future time, whether they lived to see it or not, when the truth would be acknowledged by the Church and by the State, and full justice would be done to the physical infirmities of the weakest and poorest of inebriates. Dr. Norman Kerr then left the chair, which was taken by the chairman of the morning sitting, Dr. Cameron, M.P., who briefly reviewed the law as regards inebriety and eulogised the work of the Dalrymple Home at Rickmansworth.

Dr. Norman Kerr laid before the Congress the result of a special inquiry into our colonial legislative provision for the victims of inebriety.

Dr. T. D. Crothers, in a paper entitled Inebriety and Inebriate Hospitals in America, reviewed the progress of the temperance movement in that country, the condition of the hospitals for inebriates and the work done by them, and the conditions of legal control of inebriates. He said that the history of the inebriate asylum movement in America was a repetition of every real advance in science, passing through three regular stages of growth—agitation, opposition, acceptance. It was now in the first and second stages. All investigation sustains the conviction that the time is not far distant when the inebriate will be taken from his home and on the street, and be quarantined in special hospitals, the same as if suffering from an infectious disease.

Chevalier Max Proskowetz de Proskowmarstorff stated that in Austria inebriety was increasing everywhere on a dangerous scale. The consumption of alcohol (taken as at 100 per cent.) was 6·7 litres a head in a population of 39,000,000; but in some districts 15½ litres was the average. In all Austro-Hungary there was an increase of nearly 4,000,000 florins in the cost for alcohol in 1884-85 over 1883-84. In 1885 there were 195,665 different places where liquors were sold. The national Parliament has been asked to establish homes for inebriates, and to cause the intoxicating nature of alcohol to be taught in schools.

Dr. N. S. Davis said that the conflict between the vice view and the disease view of inebriety was the result of a misapprehension of terms. A drinking parent begets a child with a degenerated type of organisation, rendering the latter liable to inebriety, as to convulsions or imbecility. Inebriety is a disease, inasmuch as it is a departure from health, persisting in certain cases after the immediate act of drunkenness is over.

Mr. Clark Bell, president of the Medico-Legal Society of New York, read a paper on the relation of Intemperance to Insanity. After reviewing the opinions of the most celebrated alienists of Europe, he said that we might safely assume that science recognises throughout the world the abuse of alcohol, not only as the greatest and most direful cause of insanity known to the race, but alcoholism in its various forms as a distinct type of insanity.

Dr. Lewis D. Mason, discussing the relation of disease to alcoholic inebriety, said that apart from those who take alcohol for social reasons, a large proportion take to it because they are diseased—first, as a stimulant cardiac primarily, then on the cerebral circulation; secondly, as an anæsthetic in painful or distressing diseases or conditions. Thus disease may be in a certain proportion of cases the underlying cause of the alcoholic inebriety, and alcohol by degeneration may produce disease which when established may produce and keep up habits of inebriety.

Rev. J. W. Horley read a paper based on his experience while chaplain of Her Majesty's prison, Clerkenwell.

Dr. Petithan, Liège, said that alcoholism in Belgium had augmented with frightful rapidity, and called for immediate and thorough action.

Mr. Axel Dickson said that in Sweden there were two asylums for inebriates. One is at Bic, under medical superintendence, where the charges can be paid only by persons of the middle class; the other is for working people at Törnas, the charges varying from £11 to £22 per annum.

Dr. Richardson explained the action of the heart and circulation in the inebriate classes by sphygmographic tracings, and demonstrated that there was a deviation from health in every stage of inebriety.

Surgeon-Major R. Pringle, M.D., read a paper on Homicidal and Suicidal Inebriety, Dr. Alfred Carpenter on the Meeting Place of Vice and Disease in the Inebriate, and Dr. Edward C. Mann, Brooklyn, U.S.A., on the Pathology of Inebriety.

Dr. Moeller stated that in Belgium they were agitating for interdiction of the inebriate, and for his seclusion in a special asylum for the treatment of his disease.

Dr. Joseph Parrish said that from 500 cases he had come to the conclusion that the majority were at the outset of the disease the subjects either of disease or accident, and had a tendency to periodical outbreaks.

In the evening a dinner, at which 250 guests were present, was held in the large hall.

THE LANCET.

LONDON: SATURDAY, JULY 9, 1887.

THE holiday season is almost upon us. By common consent that large section of the population who have come to regard an annual holiday as the best means of mental refreshment and physical recuperation elect to take that holiday in the months of July, August, or September. This custom is capable of obvious explanation, and possesses certain definite advantages. Probably the desire to escape from the hot and dusty town to bracing coast and breezy heath originated the practice, and the growing popularity of sea-bathing, which can be enjoyed to greatest advantage at this season, has helped to stereotype and perpetuate it. Our social system is so complex that the habits of one class speedily react upon those of all the rest, and so it has come about that as summer wanes into autumn our vast social machinery begins to move a little more slowly, and many are able to enjoy some respite from the monotony of daily routine.

There are those who say that the usual autumnal holiday is a strategic error in the battle of health, and urge that, instead of leaving the shores of Britain when her gardens and meadows, her coasts and her mountains, are at their fairest, we should rather choose mid-winter or early spring as a time at which to escape from frost, and fog, and rain, to the sunny winter skies of southern lands. This argument is worth the attention of those who are free to choose their own time for their holiday, and can take distant flights to Algeria, Egypt, Madeira, or Teneriffe; but obviously this is an altogether exceptional class, and for the great majority of holiday seekers the prevailing custom rests upon a rational foundation. It is in summer and early autumn that the one short breathing space in the labour of the year can be turned to the most beneficial and pleasurable account without the necessity of undertaking distant and expensive journeys. It is not every holiday seeker who has

> "All the world before him where to choose."

For the overwhelming majority the choice is limited to some easily accessible locality within the bounds of the British islands, and there can be no doubt that in such cases the months of July, August, and September offer the maximum of advantage. There are some who, feeling the heavy stress of the winter's work, make a practice of taking a short spring holiday, and frequently take advantage of the interval at Easter for the purpose. No objection need be taken to this custom on the part of those who are simply overworked, but medical experience tends to show that a spring holiday is not without its special perils for those who are or have recently been seriously ill. The weather is apt to be then more than usually capricious. It is the east wind period, when too frequently the bright skies tempt to indiscretions which are speedily punished by the keen air and cutting blast. Travelling facilities are less ample than at a later period, and many of our health resorts are only beginning to awake from their winter torpor. On the whole, spring holidays must be recommended with caution, and in many cases the invalid, at any rate, will be better advised to remain in the enjoyment of the comforts of home until he can travel with greater security.

After the *when* of holidays, the next question is naturally the *where*. In the present article we shall confine ourselves to the needs of the family or the individual in whose case change of air is sought merely as an agreeable mode of rest and recuperation, reserving special cases for subsequent consideration. We may distinguish at the outset two classes of holiday: (1) the holiday which consists of a continuous and more or less prolonged residence at some single spot, and (2) the holiday tour, whether confined within the limits of the British islands or embracing a wider area. The therapeutic uses of these two types of holiday are worthy of some distinction. The former is evidently more suitable, as a general rule, for the extremes of life, for those who are much debilitated or recently convalescent, and for those persons who wish to carry out some special line of treatment at a selected sanatorium. The holiday tour, on the other hand, evidently affords more novelty, amusement, and instruction, and may be recommended to those who are fairly robust or whose ailments are "nervous" rather than organic. The great defect of the holiday tour is that, as a rule, too much is attempted in the way of sight-seeing. There is an excess of continuous fatigue, and not uncommonly health is injured rather than benefited. The tour with a crowd is open to grave objection, and should be positively prohibited to all whose main object in travelling is the restoration of physical vigour, impaired by over-work or disease. It is less within our province to point out the defects of this form of tour from the æsthetic point of view, but the spectacle of the average *bourgeois* tourist, introduced by easy arrangements to the wonders of the Louvre or the Vatican, irresistibly suggests the well-known saying about the impolicy of casting pearls before unsympathetic quadrupeds.

For continuous residence we have the choice of sea, mountain, and inland plain. Where the needs and tastes of children have to be considered, the first-named is rightly regarded as in general the most suitable. Children, with rare exceptions, love the seaside; the waves, the sandy beach, the seaweed, and the marine animals are to them a source of continuous delight. This joy in the ocean is the natural outcome of the physical benefit which usually accrues to the child by a residence at the seaside—a benefit which is very general, and specially marked in those who have any inherited or acquired tendency towards rickets, struma, or consumption. While seaside life is almost invariably beneficial to children, it does not necessarily follow that a bath in the sea shall be included in the daily programme. It is an admirable tonic to those who have a fairly sound constitution, and especially a vigorous circulation, but in all cases of delicacy it should be used with caution. Little harm will be done if the cardinal rule be kept in view that the sea bath does good when there is a speedy and sufficient reaction, but mischief if the reaction be imperfect or long delayed. It is also a safe rule not to insist upon bathing children who regard the process with lively aversion or alarm.

We have in this country a splendid array of admirable marine resorts—Brighton, Eastbourne, Folkestone, Margate, Cromer, Scarborough, Skegness, Whitby, Ilfracombe, Tenby, Barmouth, Llandudno, Douglas, Bray, Portrush. Such are a few of the many which might be mentioned with commendation. Their physiological action may be recollected by the general law that the northern and eastern coasts are bracing the southern and western coasts more or less relaxing. Scarborough and Cromer are two of the most bracing English marine resorts, while Ilfracombe represents the opposite pole.

Of mountain resorts, in the strict sense of the term the British islands are almost wholly destitute, but such agreeable spots as Pitlochry in Perthshire and Llanberis in Carnarvonshire, although at only a slight elevation, afford the active pedestrian ample facilities for scaling heights where the desired air of the mountains may be obtained. The mountain resorts of the continent of Europe are numerous and famous. The Alps, the Pyrenees, the mountains of Auvergne, all contain delightful spots of world-wide renown, where a charming holiday may be spent amidst some of the most sublime scenes in nature.

In agreeable resorts of the third class—namely, inland resorts other than mountains—our own country is rich. Malvern, Cheltenham, Tunbridge Wells, Buxton, Matlock, Ilkley, Harrogate, Leamington, Woodhall Spa, Bath, Moffat, Crieff, and Strathpeffer form a goodly list, which might easily be increased. It will be remarked that many of the places on this list owe their celebrity in some measure to the possession of mineral springs, the revival of popularity of the British spas being no longer a hope only, but an accomplished fact. Bath is already reaping the reward of the active public spirit of her municipality, and Leamington is following so worthy an example. It cannot be doubted that the great popularity of the foreign spas is in many cases due more to their energy and ingenuity in catering for the wants and amusements of their patrons than to any decided natural superiority over similar resorts in Great Britain.

The holiday tour remains for consideration. Here the choice is limited only by time, cost, and individual taste. The Scotch highlands, the English lakes, and the wilds of Connemara afford ample scope for pleasant and health-giving tours, to which the only serious drawback is the extreme uncertainty of the weather in this changeable climate. It is matter for regret that the tourist so commonly insists upon getting over a good deal of ground, and is hence obliged to keep to the beaten tracks, where the facilities for locomotion are in full operation. Pedestrian tours of ten or fifteen miles daily offer far superior attractions for the stout walker to the stereotyped journey by rail, coach, or steamboat. To such persons may be commended the dales of Yorkshire, the green lanes of Warwickshire, the valleys of Wicklow, or the incomparable coast scenery of Devonshire, Cornwall, Antrim, and Donegal. The pedestrian, unless thoroughly inured to his work, must not exceed fifteen miles daily; he must guard against foot-soreness, and abstain from alcohol during active exertion.

For those who desire more distant flights Norway, Switzerland, the Rhine, the Tyrol, the Pyrenees, &c., offer unlimited scope and endless variety. It is a good rule in planning the itinerary of a tour to estimate carefully the time required to accomplish the contemplated round, and then to add one-third of that time in addition for rest, recuperation, and casual delays. In our next article we shall deal with the Invalid's Holiday.

THE wide publicity which was given to the outbreak of diphtheria which prevailed at Ealing in January last will be remembered. As the result of numerous representations, Mr. W. H. POWER was instructed by the Local Government Board to make inquiry into it, and his report, which is now before us, deserves careful attention from several points of view.[1] At an early stage of the disease Mr. PATTEN, the local medical officer of health, was of opinion that the diphtheria was in some way connected with the use of milk from a particular dairy, but neither he nor Dr. CORFIELD was able to detect the means by which this was brought about, whether as regards the sanitary state of the dairy or the health of the cows. The dairy owner, on the other hand, was able to show many points which went to raise doubt as to this view, and the case was admittedly one surrounded by many difficulties, for it involved investigation of a very limited but fatal outburst amongst consumers of over 1000 quarts of milk daily, the supply coming, in part, from other sources than the main dairy farm. On Mr. POWER'S commencing his investigation, circulars asking for information under a number of headings were issued throughout the district, and by the aid of such answers as were sent in it was found that households served by the suspected dairy had suffered to twenty times the extent of households having a different milk service, and so far as a "sore-throat" outbreak was concerned, this appears almost entirely to have been produced after the cause of the diphtheria had come to an end, but even then it was mainly amongst the customers of the dairy in question. The actual diphtheria outbreak was limited to seven days—i.e., Jan. 19th to 25th—and of those then attacked every one of the deaths occurred in persons consuming the milk under suspicion. It was also ascertained that antecedently to this outbreak of diphtheria there was some insignificant prevalence of sore-throat, most abundant amongst customers of the particular dairy, but not affecting them exclusively. Whilst the diphtheria was in progress sore-throat also prevailed, and this, too, amongst the same class of the population; and then, after an abrupt cessation of the diphtheria, came another sore-throat prevalence. The precise meaning of these various occurrences is discussed in detail by Mr. POWER.

At the same time Mr. POWER makes no secret of the imperfect results he obtained during the course of his inquiry. The Ealing case was a peculiar one. An intelligent officer of health was available, and the views which he held at the onset as to the cause of the disease have been confirmed; but notwithstanding this, "panic," Mr. POWER says, seized on the population, and they clamoured in the public press and elsewhere for an "independent" inquiry. There probably never was a case in which it was more necessary to get accurately at all the facts, negative as well as positive; and it may be stated at once that, so far as the implicated

[1] Mr. W. H. Power's Report on an Outbreak of Diphtheria in Ealing. London: Eyre and Spottiswoode. Edinburgh: Adam and Charles Black. Dublin: Hodges, Figgis, and Co.

Digitized by Google

dairyman was concerned, every information was absolutely placed at Mr. POWER'S disposal. But out of nineteen medical practitioners personally urged by the Ealing Sanitary Authority to give information, it is stated that not more than eleven supplied facts of the sort asked for, eight sending either no reply at all, or refusing the names and addresses of their patients; and some of the private residents also refused information. Under these circumstances, Mr. POWER, after having at great labour put together a large number of extremely interesting facts, is obliged to conclude his report by stating that "questions further arising have not admitted of study on the present occasion, and consequently an opportunity has been lost of getting knowledge on this difficult subject." The aid which the Medical Department of the Local Government Board are able to give to communities affected with epidemic disease is necessarily limited by the small staff at their disposal, and by the necessity for doing such work as they undertake in a complete and exhaustive fashion. It seems, therefore, regrettable that they should not be furnished with the fullest possible information.

FATIGUE seems a simple word with a clear meaning, but how dark are the physiology and pathology of the subject is borne witness to by the elaborate researches of which it has been the centre, and the incompleteness of the solution of even its elementary problems. A thorough understanding of "fatigue" would include accurate knowledge not only of a physiological, but of a physical, chemical, and even psychological kind. Then, again, its influence as a means of treatment of disease or its effects on the already deranged organism is of interest to every medical practitioner. The most important branch of the question, however, relates to the nervous and muscular systems. In the process of getting fatigued, long before exhaustion sets in, what special parts of the neuro-muscular apparatus first become *hors de combat?* Many observers have endeavoured to elucidate this vital element of the question. Some of the latest consider the weakest link to be the peripheral apparatus, and the best researches at least support such an opinion. In his very interesting papers on Writers' Cramp and Allied Affections, contributed to the Royal Medical and Chirurgical Transactions, Dr. G. V. POORE has brought forward many facts connected with the living human body tending to support the hypothesis which locates the mischief in such cases in the peripheral apparatus. The experimental evidence adduced by Dr. AUGUSTUS WALLER is confirmatory of such a view, and, besides, is of a highly suggestive character. It is difficult to assign adequate reasons for the notion, but *a priori* we should expect that the points of junction of any apparatus would prove the weakest parts thereof. And so it apparently is in the neuro-muscular apparatus. The weakness appears to exist neither in the nerve cell of the motor cortex, nor perhaps even in the motor cell of the spinal cord, nor further down in the muscle itself, but rather in the junction between the pyramidal fibres and the motor cell of the cord and the similar place (the motor end-plate) in the muscle. An analogy between these two sites has been clearly drawn by Dr. GOWERS, who pertinently suggests that some agencies—disease as well as drugs—may paralyse the terminations of the pyramidal tracts in a similar way that curare, and perhaps other agents or agencies, destroy the function of the motor end-plate.

Another important point to be decided before we can be fairly considered to have any real knowledge of the nature of fatigue is the causation of the nutrition of these terminal organs—the actual conditions on which they depend for their existence as functional elements. All the information at present at our command would seem to show that the periphery is at the mercy of the centres; that the central motor cells can live and have their being without the aid of the terminal ramifications. And the evidence appears altogether opposed to the belief that any "mutual tension" exists between centre and periphery, though such a belief is entertained by Dr. BROADBENT and others. Easy as the matter seems of experimental demonstration, a further consideration clearly shows the vast difficulties in the way of settling even the simplest points in the problem. Dr. WALLER thinks there is evidence of a trustworthy character tending to prove that the nerve trunk lasts longer than the motor end-plate; that repeated stimulation of the latter causes its functional death before the disappearance of the function of excitability of the nerve. In the nature of things, a definite proof of this problem could only be ascertained by the employment of delicate instruments of research, whose indications, though accurate so far as they go, are yet liable to errors of interpretation. A deflection of the needle may be significant of the passage of a genuine impulse along the nerve which forms part of the circuit—the true negative variation; but accidental currents may cause confusion, and the phenomena attending the electrotonic state are not amongst the most simple in physiology. If matters are no better advanced in the sphere of neurology, what shall we say when we turn to the process of fatigue in other organs? Nor are the pathological manifestations sufficiently understood, a fact of which we are reminded by the work of ANGELO MOSSO, of Turin. He states that fatigue carried beyond the moderate stage, at which it is decidedly beneficial, subjects the blood to a decomposing process through the infiltration into it of substances which act as poisons—substances which, when injected into the circulation of healthy animals, induce malaise and all the signs of excessive exhaustion. That the chief cause of fatigue is the production of certain products and their action on the tissues is not a self-evident proposition, because it seems to be clear that any tissue excited unduly in a given space of time must become exhausted. And it is equally possible that fatigue as a sensation may be caused by the negative condition of diminished reconstruction as by the positive one of actual irritation by the products of metabolism. The facts at present ascertained would seem to prove that the negative and the positive states are both operative in the causation of fatigue.

THE 30th of June, 1887, "the day appointed" by their Lordships of the Privy Council under the Medical Act of 1886 and for certain purposes contemplated in that Act, is now past, and we may profitably devote an article to the consideration of the Act as a whole, and to the bearing of it on the future of the profession in the United Kingdom and its dependencies.

Perhaps the provision of the Act on which its promoters

Digitized by Google

and admirers would most pride themselves is that which defines a Qualifying Examination for the future to mean an examination in *Medicine*, *Surgery*, and *Midwifery*. Hitherto *Midwifery* has been left out in the cold very much. In a court of law, for purposes of recovering charges for obstetric services, a midwife of the old order has been almost in as strong a position as an eminent obstetric physician, and even a little stronger, inasmuch as she was not hindered as he is by the bye-laws of his College from taking legal measures to enforce the payment of fees. Henceforth, in law, Midwifery is recognised as an indispensable part of medical education, without a knowledge of which no person shall be put on the Medical Register. Not only so, there must be also proof of knowledge of both Medicine and Surgery. Hitherto bodies were excused in law if they examined a man in one-half only of his profession—in Medicine or Surgery; now they must examine in all three subjects mentioned above. Of course this is as it should be. But the credit to the Act is not so great as it seems; for, as a matter of fact, nearly all the authorities have for some time been examining in all three subjects, though technically they, with one exception, conferred a diploma only in regard to one—Medicine or Surgery. The gainers will be chiefly the medical authorities and corporations, who will have a sort of excuse for charging a double set of fees for what is practically one examination, capable of being conducted by one body, which double set of fees will be of very unequal amount in different divisions of the kingdom, and in England and Ireland a very heavy charge for what is after all a minimum qualification to practise. The Act practically makes every corporation *per se* unable to give a complete and legal qualification, and so requires their conjunction or the appointment of assistant examiners by the Medical Council. In the former case both the conjoining corporations expect to be indemnified against loss of fees, and the luckless candidate will have in future to pay, as we have said, two Bodies for what could easily have been done by one. It remains to be seen whether the great disparity of fees charged by the corporations still left to compete with each other will operate injuriously on London schools or to the disadvantage of the public. We should have admired this much-praised feature of the Act if it had achieved a complete examination with more justice to the student and more security of moderation and equality of terms in the different divisions of the kingdom. It will be interesting to see if the conjunction and co-operation imposed on Corporations, which have hitherto cultivated the notion that a physician and a surgeon are essentially different and incompatible beings, will have any effect in widening the culture and the charity of each.

Another great feature of the Act of 1886 is the creation of Inspectors to secure the maintenance of the standard of proficiency in candidates at the said qualifying examinations. Three such inspectors, men of high character and fitness, have been already elected. Such a small number can scarcely do full justice to the work; but they will do their best; and if they give us a fair report on the Final Examinations, to which their present attention is to be restricted, they may well justify their existence. They will best do so by perfect frankness and independence. They come into office when the attention of the profession is directed to the disastrous rejections in practical subjects. They will perhaps tell us the explanation. The gift of a new lease to the Apothecaries' Societies is a feature of the Act which has already been fully discussed. The next change effected by the Act was a change in the constitution of the Council. Not only is there given for the first time a Direct Representation to the profession, but for the first time also a direct and independent representation to every Medical Authority. The half-representation of the Scotch universities has been removed; but they have no more voice in the Council than the Apothecaries of Dublin or the Faculty of Glasgow. We are not ungrateful for small mercies, but it would be absurd to affect satisfaction with so large a Council in which twenty bodies are so minutely and individually represented.

The recognition of Foreign and Colonial degrees by a nation which expects its own diplomas to be recognised everywhere was inevitable, and, if care be taken, need not injure either the public or the profession. The last, but by no means the least, feature of the Bill is the free importation of the Privy Council into the settlement of many questions affecting medical education and examination. Reports of inspectors of examinations are to be forwarded by the Medical Council to the Privy Council. And "if at any time it shall appear to the Privy Council" that the General Council is not doing its duty or maintaining a sufficient standard in the qualifying examinations, the Privy Council may notify their opinion to the Medical Council; and if the Medical Council fail to comply with any directions of the Privy Council, the Privy Council may supersede the Medical Council.

Such is the Act under which, "for better, for worse," the profession is to be regulated in the immediate future. It is badly drawn, and open to much criticism. But if the medical authorities which it recognises or creates do their duty in an unselfish way, perhaps the result may be better and juster than may have been anticipated.

Annotations.

"Ne quid nimis."

PROJECTED CHANGES AT THE COLLEGE OF SURGEONS.

SOME important changes, both in the College itself and in its *personnel*, were decided on at the last meeting of the Council. Among the latter we notice with pleasure that a pathological curator is to be appointed, whose whole time and service shall be devoted to his duties at the College. This is so wise a determination, and so obviously in the interests not of the museum only, but also in the interests of pathological anatomy, that it will be received with acclamation by the whole profession. The Council have done well to determine that this officer shall give his whole time, and shall not practise. We should be glad to know that he will be required to give lectures on surgical pathology, so as to keep the profession well posted in the latest interpretation of pathological facts. It would, perhaps, be too much to expect another series of lectures, such as those delivered by Sir James Paget many years ago and since published; they may nevertheless serve as a model towards which to aspire, and may help the future incumbent of the new office to shape both his

Digitized by Google

work and his ways. Another duty, of hardly less importance, if we may venture to say so, should be the weeding out of old useless specimens. If this were done thoroughly, we are convinced that there would be little need at present to enlarge the museum. Hitherto, too much attention has been devoted to the acquirement of gross specimens; there are scores of tumours of different sizes and shapes which have no sort of value for a museum, and which, without the clinical history, are quite void of interest as well as of instruction. More attention should be given to the minute structure of such growths, and to the preservation of carefully made microscopic preparations. Acting on the recommendation of the Committee on the Extension of the College Premises, the Council have definitely determined to pull down the two houses immediately adjoining the College, the one to permit of an extension of the library, the other to serve as a residence for the conservator, after being suitably rebuilt. As regards the enlargement of the library, we quite feel that this may be a necessary step; and if it can be adequately accomplished "at an approximate cost of £2500," no very valid argument against the proposal can be made. As regards the rebuilding of No. 38, Lincoln's-inn-fields, "now occupied as chambers on annual tenancies," there is greater room for doubt. For besides the outlay on rebuilding, there will be the annual loss of rents. Then it is somewhat questionable whether the conservator need actually live on the premises. Many conservators would prefer to live out a little more in the country, and thus some valuable property would be at the disposal of the Council. We sincerely trust that these structural changes will satisfy the yearning for extension which seems to have overtaken the Council contemporaneously with the realisation of Sir Erasmus Wilson's great legacy. There are many other and far more important uses to which this money might be put, and these have been signified to the Council over and over again from many different sides—time alone will show with what result.

THE RELATIVE RANK OF ARMY MEDICAL OFFICERS.

IN the discussion which has taken place on the subject of the rank of army medical officers, nothing has struck us as being so remarkable as a suggestion offered by a contemporary as a "healing measure" by which the authorities might give evidence of their real desire to give satisfaction to the Army Medical Service. The suggestion is, "Let them restore this warrant [of 1858] in its integrity, and let future War Ministers set their faces firmly against all insidious attempts on the part of those who have more regard for their own class privileges and prejudices than for the best interests of the public service." Now let us examine what the practical results to the army medical officers would be of the restoration "in its integrity" of this Warrant. It would restore to them the duty of sitting as members of mixed boards, and as president when they happened to be the senior officer, instead of being, as at present, exempted from serving on such boards in any capacity; and it would also revive the extinct grade of assistant-surgeon. In exchange for these boons, if boons they can be called, it would deprive them of the right to retire with a gratuity at various periods under twenty years' service, of the right to retire on pension after twenty instead of twenty-five years' service; it would reduce the army rank of every grade of medical officer except surgeons-major under twenty years' service; it would lower the pay and retired pay of every grade, and would check the course of promotion by the return to the age of sixty-five years as the period at which medical officers of the administrative grades must retire instead of sixty years as at present, and by the abolition of the grade of brigade surgeons. That such a measure, if demanded by the department, might be acceptable to "Mr. Secretary Stanhope and his advisers" is possible, because it would carry with it a considerable money saving; but that it should be asked for by the department, or accepted by them as "a healing measure," is utterly beyond our belief. That the Warrant of 1858 was an acceptable measure, that it did much good, and was fully appreciated by the department, are well-known and undeniable facts; but since that date great and important changes have taken place in the army, and valuable concessions have been made to the demands of the profession on behalf of their brethren in the Military Service. Is it possible that an Act cancelling all these concessions and reverting to a state of affairs which was deemed satisfactory nineteen years ago would prove acceptable or "give satisfaction to the Army Medical Service"?

THE TREATMENT OF LUPUS BY INJECTIONS OF CORROSIVE SUBLIMATE.

DR. IGINIO TANSINI, of Lodi (*Gazzeta degli Ospedali*, June 12th), narrates the treatment of a case of lupus of the nose and face by means of repeated injections of corrosive sublimate. He began with a weak solution: corrosive sublimate 50 centigrammes, distilled water 100 grammes. This produced no reaction of any kind. A stronger solution—corrosive sublimate 1 gramme, distilled water 100 grammes—was then used. This produced some tumefaction and œdema in the neighbourhood of the punctures, and slight suppuration in some of them. Some fourteen or fifteen injections of a few drops were practised. Improvement soon became marked, and eventually all traces of the disease disappeared, the only marks left being those of the punctures in which suppuration had taken place. Dr. Tansini was led to try these injections by the following considerations:—1. That lupus is a form of tubercle. 2. That the bacilli are few and have no tendency to diffuse themselves. 3. That corrosive sublimate has proved certainly destructive to bacilli. He claims advantages for this method on account of lessened pain and disturbance and superior cosmetic results.

SUDDEN DEATHS.

SUDDEN deaths are almost necessarily frequent at times when the conditions of life change suddenly, or are especially changeful. It matters little to the result whether the change effected be for the better or for the worse, relatively. Thus it may be more favourable to the needs of a particular life that the temperature should be high than that it should be low, yet the change from cold to heat may be so rapidly effected as to throw upon the circulatory and transpiratory functions a strain which those parts of the organism which are concerned in the performance of the work required are unable to bear. In this way it happens that persons with unsound or weak hearts, or weak arteries, die suddenly when the temperature rises rapidly, although, if only there were no special strain consequent on the change, it would in itself prove advantageous to them. The converse is true, and without going into details which it is needless to particularise, it may be laid down as a proposition which cannot be disputed that at periods of seasonal change, and at times when the weather is so changeful as to produce great and rapid variations of temperature and pressure, sudden deaths are especially—we may even say *naturally*—likely to occur, and must, as a rule, be numerous. It cannot, therefore, be held to be surprising that the record of events of this class has been a heavy one during the past few weeks. The deductions to be drawn from the facts of the subject are—first, that a very

Digitized by Google

large proportion of these calamities must be regarded as distinctly avoidable; and, second, in a considerable number of instances the difficulty of avoiding death would have been extremely small. In truth, it is little short of madness for persons who know themselves to be organically unfit, or weakly, to take exceptionally violent exercise—for example, in the cricket field—before the organism has had time to adapt itself to conditions which have been quickly changed. We are not now speaking of persons with recognised heart disease, who, of course, ought not to indulge in arduous sports at all. Our remarks are intended to apply to the cases of persons who, not being "diseased," are scarcely in robust health. It is strange that persons who escape for a few hours or days the monotony of a sedentary occupation generally set themselves, without preparation of any kind, to perform feats of muscular exercise which would severely tax the strength of those who are habituated to this sort of work. It seems to be forgotten that to suddenly change the mode of exertion is practically to call upon parts of the organism which are more than likely to be out of order and incapable of performing the task required of them, whether it be walking, climbing, playing games of muscular activity, or even exposure to more than an accustomed amount of excitement of any description. It is unwise—because unsafe—to assume that the brain or body generally will be able to do what is asked of it without preparation. It is for the most part out of small errors of self-management that great disasters to health and life are developed. It ought, therefore, to be remembered and impressed on holiday-makers of all classes that no unaccustomed exertion of any sort should be attempted without such care and preparation as a common-sense view of the matter suggests and enjoins.

HEALTHY HOUSES FOR THE LABOURING CLASSES.

THE proper accommodation of artisans and their families in town or country is an object still so far from attainment that almost every new suggestion relating to it is possessed of interest. The future of the country as a working and prospering unit is far more nearly connected with the healthy vigour of its native labouring population than with its natural products or its reserve of capital; and as strong muscular power cannot be reared in crowded homes planted in an unwholesome atmosphere, it behoves us to find for it those healthy surroundings which are so indispensable. In London and other great towns the work of providing suitable house room is fortunately making some progress. Much, however, remains to be done, and there is a good deal to be said for the contention of Lord Henry Bruce that this is a matter in which private enterprise, to be efficient, must be largely assisted by the various local authorities. He speaks, indeed, with special reference to London, but his remarks might be applied with more or less fitness to the case of any of our large towns. His complaint is that the Metropolitan Board of Works, while it has condemned many areas as insanitary, has remodelled very few; while, on the other hand, it has not forgotten the more attractive part of its functions, but has, perhaps, done it more than justice by opening up new streets and showy thoroughfares. It must be said in defence of the Board that its duties are manifold, and require a reasonable time as well as method for their execution. We must remember, also, that the demolition of slums is a gradual process, and implies a simultaneous provision of house accommodation for their occupants. Still, the fact that many thousands of families in the metropolis inhabit only one room ought to prove that there is need for increased activity; and it will not fail, we hope, to exert its full effect upon the mind of the Board and of the public. In rural districts a good deal has been made of the compulsory allotment of land to agricultural labourers. The project, if economically practicable, has certainly this in its favour—that it will help to stem that influx of the country population into towns which threatens, if continued, to drain the former of much of its best working material, while the close life of the towns must tell somewhat against the health of the in-comers. A modification of this system has lately been suggested by Dr. Downes at a meeting of the Essex Chamber of Agriculture with a view to improving the sanitary state of labourers' cottages. He proposes that rural sanitary authorities should be empowered to compel the sale of vacant land to cottage owners to be apportioned so that every such dwelling shall have attached to it a garden-plot of about one-eighth of an acre. The particular advantage claimed for this plan is that it will allow of more efficient removal of sewage than is now possible in the case of those small houses where underground drains are not used. The facilities for tillage, the greater supply of fresh air per house, and the consequent advantage with a view to isolation in case of infectious disease, are other reasons why the proposed arrangement, if it can be got to work, should prove satisfactory. The chief obstacle is the financial difficulty of securing to the purchasing owner a due return in rent for his outlay. We have not space to enter into this question, but it is so far satisfactory to know that the scheme is considered a practical one by the Essex Chamber of Agriculture.

TOMMASI-CRUDELI ON MALARIA.

THE last addition to the already voluminous bibliography of this subject is the elaborate "note" recently submitted by Dr. Tommasi-Crudeli to the Royal Academy of the Lincei, entitled, "Stato attuale delle nostre Conoscenze sulle Natura della Malaria e sulla Bonifica dei Passi Malarici" ("On the present State of our Knowledge as to the Nature of Malaria, and as to the Reclamation of Malarious Countries"). The paper is a reply to the author's many critics, and his fair and courteous tone is quite as remarkable as the trenchant force of his dialectic. Without entering into the arguments with which he seeks to remove objections, or to add confirmation to his position, we may admit that he has shown reasonable cause for adhering to the conclusions set forth in his now well-known treatise on the "Climate of Rome," reviewed in THE LANCET of October last. Even as a working theory of the origin of malaria and its remedy, it is not too much to say that his doctrine still holds the field, while he can claim the independent investigations of pathologists like Mosso of Turin as yet further reinforcing that doctrine. The concluding section of his paper refers to the treatment—the prophylaxis, rather—to be adopted in malarious countries, and he still holds to his belief in the preventive utility of arsenic, as "augmenting the mean resistance of the human organism to the invasion of the malarious ferment." Often enough he confesses this end is not obtained because in many cases the "specific resistance" has already sunk below the "mean resistance," either through defective or deleterious alimentation, or through long-continued depression, moral as well as vital, or through previous malarious attacks. Dr. Ricchi, medical supervisor of the South Italian Railways, and now of the Adriatic network, has, at the instance of Tommasi-Crudeli, set himself for some time to obviate these adverse conditions; and to aid the preventive virtue of the arsenic, he has prepared an aliment which has been found materially to answer that end. It consists of a powder, impalpable, soluble in water, in coffee, in broth, and such-like, prepared with the "sterilised" and desiccated blood of calves, and now known to commerce under the name of "Trefusia." The composition, quite accessible to the very poor, "has served," says Tommasi-Crudeli, "to render resistant to malaria those whose organisms, already deteriorated, were

Digitized by Google

not susceptible of protection by the arsenical treatment alone." He further reiterates his confidence in the decoction of lemon as a prophylactic, and even as a remedy, in cases in which quinine and arsenic have failed. In testimony of this he adduces the experience of Professor Colasanti and of Drs. Taussig and Ferraresi of Rome, and of Dr. Shakspeare of Philadelphia, all of whom have noticed the efficacy of the decoction in every stage of malarious disease.

MORTALITY OF COTTON OPERATIVES IN OLDHAM.

IN an appendix to a valuable report recently issued by Dr. Niven, the medical officer of health for Oldham, on the health of that borough in 1886, the results are published of a preliminary inquiry into the effect of the cotton industry upon the health of the population in that town, more especially as regards the mortality from acute diseases of the respiratory organs and from phthisis. The inquiry is unfortunately beset with as much statistical difficulty as it is full of interest. Dr. Niven has attempted to gauge the influence of this occupation upon the mortality from the above-mentioned diseases by comparing the proportion between the deaths from these diseases among the total population of the town aged between fifteen and sixty years, with the proportion of such deaths at the same ages among persons engaged in the cotton industry. The conclusion at which Dr. Niven arrives, after what he holds to be ample allowance for possible sources of error in the application of his method, is that "the cotton operatives do not suffer more from phthisis than the general population, and that they suffer decidedly less from bronchitis and pneumonia." It will be eminently satisfactory if this somewhat surprising conclusion can be established as entirely trustworthy, but it is necessary to point out one or two obvious defects in Dr. Niven's method, which he will probably be one of the first to admit. In the first place, we find it difficult to see how, if Dr. Niven wishes to ascertain the effect of occupation in the cotton industry upon health, his object can be furthered by embracing in his inquiry the mortality statistics of the husbands, wives, sons, and daughters of cotton operatives. This might be desirable if the inquiry were one into class mortality instead of occupational mortality. Moreover, this extension of the inquiry considerably adds to its statistical difficulty, as the Census Report gives no clue to the numbers of persons *dependent upon* the cotton industry. The Census Report for 1881, however, states that 28,949 males and females were in that year actually engaged in "cotton, cotton goods manufacture," and Dr. Niven estimates the number engaged in the trade at 35,000 in 1886. Another source of difficulty inseparable from Dr. Niven's method is that of age distribution, which must differ very widely in the cotton industry from that in the general population. The partial correction for this disturbing influence by omitting all under fifteen and all over sixty is quite inadequate for the purpose, as the age distribution between fifteen and sixty must differ widely enough to render the conclusions of Dr. Niven of somewhat doubtful value. It should be borne in mind that the result of Dr. Ogle's investigations into the subject of the comparative mortality of males aged from twenty-five to sixty-five engaged in different industries during the three years 1880-82 differs considerably from that arrived at by Dr. Niven. Among men engaged in the cotton and linen manufacture in Lancashire, Dr. Ogle gives for phthisis a mortality figure of 272, against 220 for all males; while the respective figures for diseases of the respiratory system are 271 for the cotton industry and 182 for all males. It is needless to say that Dr. Ogle's figures are more in accordance with the general impression of the effects of cotton factory labour on health than are those of Dr. Niven. We shall look forward with interest to further investigation of the subject by Dr. Niven and other medical officers of health in towns where the population is mainly engaged in the cotton industry. It is necessary, however, that the disturbance due to varying age distribution of the populations dealt with should be fully and carefully guarded against.

OVER-PRESSURE AND TYPHOID.

M. PETER made a distinct contribution to the pathology of over-pressure in the striking paper he read on the 28th ult. before the Académie de Médecine. Having drawn a trenchant distinction between *sur-ménage volontaire* and *sur-ménage involontaire*, and reviewed the various injuries to which the developing school-boy is liable under the severe competitive ordeal to which he is nowadays subjected, he showed that the *courbature cérébrale*—the analogue of the *courbature musculaire*—may have fever not only as its sequela, but almost as its concomitant. Febrile disturbance, most frequent in the summer months, because at that season examinations and competitions are in full blast, may attain in the *surmené* to actual typhoid; for not only is there in these special cases a general rise of temperature, the thermometer often indicating as much as 39° and 40° C., but there are, as M. Peter has had occasion to remark, epistaxes and diarrhœas—symptoms which disappear with the cessation of the *sur-ménage*. This fever is well known, he says, in convents, where the ladies superior have learned to enjoin immediate relaxation of brain tension as the only remedy. M. Peter has noted cases in which one member of a young family, living under precisely the same conditions with the others, drinking the same water, eating the same food, and breathing the same air, has yet had to be treated by him for typhoid, the predisposing cause in the case being the long-continued pressure of preparatory study, a systemic nidus being thus developed, in which the *microbe pathogène* finds everything ready for its evolution. Many of his data have been drawn from the École Polytechnique, where he shows that, even more commonly than fever, phthisis is induced by the high-pressure life the pupils lead under conditions unfavourable to the renewal of healthy tissue. Having shown the unrelieved strain these young minds are subjected to, in view of the test examination, he dwells also on the muscular inaction, the rebreathed air, the constrained posture, and, last of all, the inadequate alimentation which is their portion: "At 6 A.M. a little black coffee and bread, and the first 'square meal' at 2 P.M.; in other words, seven hours' severe head work on an empty stomach. And the second meal does not take place until 9 P.M.—just," adds M. Peter, "when they are going to bed." It is difficult in these circumstances to resist his conclusions that the *lycées* and *écoles* of France are in urgent need of reform.

A PLEA FOR OUR HORSES.

THE sufferings of horses in the streets of London during the summer months cannot fail to excite feelings of compassion in the mind of every humane person. The increased strain upon them, from the slippery state of the asphalte and wood pavements, the state of thirst arising from the heat to which they are exposed and the sweating consequent on their exertions, are all factors which might, by judicious arrangements, be considerably modified. But there is yet another subject which cannot fail to excite feelings of indignation—the brutal cruelty of many of the drivers, who appear to make up for their own feelings of discomfort by lashing their horses and striking or kicking them when, through exhaustion, they are unable to do what their drivers consider a satisfactory amount of work. The interference of humane passers-by rarely leads to any satisfactory result, and they can hardly be expected to take all

Digitized by Google

the trouble and give up the time necessary to have the offenders punished. But we think it is a point on which Sir Charles Warren might do good service by issuing orders to the police to take out summonses in all cases in which they see cruel treatment inflicted. We would also suggest to the owners of draught horses the duty of seeing that either the bearing rein be abolished, or that at least it be so used as not to be an instrument of torture, which it too often is in the hands of coachmen in the fashionable quarters of London.

ARSENICAL WALL PAPERS.

IT is well to give a note of warning that, in spite of utterances to the contrary, many of the gaudy-coloured wall papers are contaminated with arsenic to a not inconsiderable extent. It has been known that certain shades of green are made with arsenical pigments, and that "flock" papers with a rough surface are peculiarly dangerous from the liability of the flock to be rubbed off and disseminated as a fine dust in the air. This is so generally and so well understood that there can be but little sale for papers of the "green flock" type. An arsenical pigment is one in which the element arsenic enters definitely into the composition of the coloured compound. The green compounds of arsenic and copper and the yellow and red sulphides of arsenic are true arsenical pigments, and as such are especially dangerous. The danger is not limited to these gaudy colours, and it is well to be aware that arsenic acid is used in the preparation of many pigments which are not properly "arsenical." In these it is used as an oxidising agent, and is often imperfectly removed from the manufactured article. Arsenic acid is used largely in the preparation of "aniline pigments," and is often present in these pigments "as an impurity" caused by carelessness in manufacture; but whether arsenic be present by carelessness or intention is a matter which signifies little to the sufferer. It is well to remember that the colour of the paper is no guide to its being contaminated with arsenic. It is liable nowadays to be found in papers of all shades and tints. The pigment known as "fuchsine" is stated by Hoffman and Ludwig to be very commonly contaminated by arsenic, and they assert that of six specimens bought by them only one was found free from arsenic. In the same way the colour known as "magenta" is very liable to contain arsenic owing to the very free use of arsenic acid as an oxidising agent in the process of manufacture. In short, arsenic is so useful in the Arts in the production of pigments other than those which are essentially "arsenical," that the greatest caution is necessary before employing any coloured paper for decorative purposes. Happily the detection of arsenic is not difficult, and may be effected by persons possessing an elementary knowledge of chemistry. As a preliminary test, perhaps that known as Reinsch's test is most convenient. This consists in boiling portions of the suspected paper with distilled water, to which a fourth part of strong and pure hydrochloric acid has been added, and into which a slip of bright copper foil has been introduced. If arsenic be present, a greyish film will be deposited on the copper. This is not conclusive as to arsenic, as some other metals will also cause a film to be deposited on copper under these circumstances. As a confirmatory test Marsh's apparatus may be used. Hydrogen is generated by acting on *pure* zinc with *pure* distilled water and pure sulphuric acid. To the mixture is added a decoction of the suspected paper made by boiling with pure hydrochloric acid. If arsenic be present, arseniuretted hydrogen will be formed, which burns with a bluish-white flame and deposits a film of arsenic on a cold porcelain surface introduced into the flame. Certain confirmatory tests would be necessary to be sure that the deposit is not due to antimony. Antimony, however, is not a common impurity of pigments, and we shall not be wrong in advising that any wall papers which, when treated as we have directed, give a film on porcelain, should be at once discarded. If a wall paper which is already *in situ* be found to contain arsenic, it should be removed, or, if this be not practicable, it should be sized and doubly varnished, and the varnish should be renewed every year or so.

FEVER HOSPITAL ACCOMMODATION.

DR. TATHAM, medical officer of health for Salford, has presented to his authority an excellent report upon the hospital requirements of their district. Not infrequently sanitary authorities, in their desire to avoid expenditure, provide hospitals on sites which are insufficient when the increase of population necessitates the extension of the building. Dr. Tatham has properly pointed out that a site of ten acres of land should be procured, in a situation reasonably accessible to the bulk of the working classes, and has discussed in detail the manner in which this site should be utilised, and the character of the buildings which should be erected upon it. In instructing Dr. Tatham to lay before them a full account of the hospital which is required the sanitary authority have shown much wisdom, and in adopting his recommendations they will be able to congratulate themselves in being free from the risk to which some other authorities are exposed, of having to abandon the site when the growth of the town has rendered it insufficient for their purpose. It would be well if all sanitary authorities had the foresight of that of Salford. The planning and arrangement, and the details of construction, so far as they relate to health, are described in the report, and much judgment shown in the recommendations which are embodied in it. Salford will, doubtless, desire to possess an institution having all the advantages which the best medical knowledge shows to be necessary, and Dr. Tatham's paper will render them important service in this direction.

QUARANTINE IN THE RED SEA.

DR. ABBATE PASHA, the delegate of the Egyptian Government to the International Sanitary Conference of Rome, has just issued a paper on the "Neutralisation Quarantenaire" of the Suez Canal. Abbate Pasha's arrival in Rome seems to have been timed to prevent his doing anything more than present a memorial, which was never discussed, in which he maintained that the English proposal to allow of the passage of the Suez Canal without prior quarantine detention was the only reasonable solution of the difficulty, and he explained how this should be done by allowing the passage of vessels "in quarantine"—that is, without communication with the shores of the canal. In this respect his views were far in advance of those held by the majority of European delegates, and they were diametrically opposed to those of his Turkish colleague. His late arrival, which he naïvely explains as due to *raisons de force majeure*, was, under such circumstances, not altogether free from ambiguity; but not having had an opportunity of setting forth his views in detail at the Conference, he has done so in his present report. He strongly maintains that the present quarantine restrictions in the Red Sea are not only illusory, but ridiculous, and, as indeed must be generally admitted, in no way protective of the health of Europe. In some detail he sets out the administrative changes necessary to give effect to his views, and he proceeds to point out the advantages of allowing all vessels properly equipped from a sanitary point of view to pass the canal whatever illness may be on board, communication being sent to the ports of arrival, so that all needed measures of precaution may be at once prepared and set in motion. Far better, he

Digitized by Google

says, to leave all doors thus open, than to close the entrance to the canal and go through a series of fantastic and useless performances which abound in cruelty to those who, whether sick or healthy, are, under the quarantine laws, set down in the deserts of Arabia. Dr. Abbate deserves the thanks of intelligent sanitarians for having thus publicly expressed views, the value of which is the greater on account of his long personal experience of the *tracasseries absurdes* now performed off Suez.

PUBLIC HEALTH IN AMERICA.

IN the address on State Medicine delivered before the American Medical Association, Dr. Rohé of Baltimore gave a summary of the progress that had been made in the knowledge of the means for preventing disease, and urged that the watchwords of the practical sanitarian of the future must be: "The compulsory notification of infectious diseases, the prompt and effective isolation of the sick and infected, and the thorough disinfection of all infected articles and sources of infection." He attributed to these three factors mainly the good results which had been obtained in many parts of America, leading to a reduction in Michigan of the number of deaths from scarlet fever of 338 per year. In Memphis, moreover, the general death-rate had fallen from 35 to 23·8 per 1000 of population, and in Chicago from 25·7 to 19·5 per 1000. In America, where the adoption of new thought is easier than in older countries, it may be anticipated that this progress will encourage all parts of that great continent to adopt similar means for the prevention of disease, and that the old methods of quarantine which Dr. Rohé condemns will give place to a more rational system. America evidently requires as active sanitary administration as other countries, and particularly with regard to food supplies, the results of analysis during one year in Massachusetts and New York showing that of the more common articles of food more than half the samples examined were adulterated, whereas the analysis of drugs gave results which were no better.

DIPHTHERITIC CONJUNCTIVITIS IN A YOUNG INFANT.

DR. COPPEZ of Brussels mentions in *La Clinique* a case to which he was called in consultation where an infant of nineteen days old had been suddenly attacked with true diphtheritic inflammation in both eyes—a circumstance extremely rare, even if not actually unique, as Dr. Coppez seems to think. He observes that von Graefe and Wecker have both stated that newborn infants are not liable to diphtheritic conjunctivitis, and though there are, he says, 120 cases of purulent conjunctivitis neonatorum annually in Brussels, of which at least a third present diphtheritic complications due for the most part to too zealous applications of caustic remedies, no case of veritable diphtheria has ever before been noted. Dr. Coppez does not at all believe that the pus from a case of purulent ophthalmia can cause purulent, catarrhal, or diphtheritic inflammation indifferently, as held by some authorities, for in all the numerous instances in which he has performed inoculation, as well as in those he has seen where it has been brought about by accident, he has invariably found the resulting inflammation to be purulent like the original affection. In the present case the child was weak and puny, having been brought up on the bottle; it presented, besides, a considerable patch of intertrigo; there was no syphilitic history. It was elicited that two days before the child was taken ill it had been out, and had been in a locality where there were several cases of croup. The eyelids were much swollen, and the skin was of a dark-red, contrasting signally with the rest of the face, which was very pale. It was a matter of considerable difficulty to evert the eyelids, and when this was accomplished the conjunctiva could be seen to be of a yellowish-grey colour dotted over with ecchymoses. There was no discharge at all, the whole surface being indurated and dry. The eyelids were remarkably hot. The treatment adopted was the frequent instillation of lemon-juice and the constant application of lint wetted with iced solution of boracic acid. For two or three days the local as well as general condition of the child gradually grew more alarming, and it became quite impossible to evert the upper eyelid; the cornea, too, had become dull all over. It was difficult to suggest any more active treatment; leeches were contraindicated by the debilitated condition of the child, calomel by the diarrhœa actually present, and mercurial inunctions by the diseased state of the skin. Locally, slitting up the external canthus and scarifications were thought of, but only to be rejected on account of their very questionable utility in diphtheritic ophthalmia, even in robust subjects of full age. It was decided, however, to add eserine applications to the other treatment. In two days' time, the instructions having been most conscientiously carried out, a manifest improvement had taken place, and in about a week more the child was convalescent, the cornea being perfectly bright and clear.

THE CHALMERS HOSPITAL, EDINBURGH.

THE directors of the Chalmers Hospital, Edinburgh, have offered the post of honorary physician to the institution to Dr. G. W. Balfour, who has accepted their nomination. He takes office in the room of Dr. Halliday Douglas, who recently resigned the appointment after many years' tenure of the post. Dr. Balfour is vice-president of the Royal College of Physicians of Edinburgh and consulting physician to the Royal Infirmary. His well-known contributions to medical literature and the honourable and leading position he has so long occupied among his professional brethren in Scotland are features that will render his appointment a popular one, while the general public may well be gratified that services so much appreciated while rendered in the Royal Infirmary are again placed within the reach of the sick poor through the medium of another charitable institution.

DRUNKENNESS IN SCOTLAND.

THE *Scottish Leader* is properly concerned at the drunkenness which still exists in Scotland. There are, it is stated, 40,000 persons a year in this part of the United Kingdom brought up on a charge of drunkenness, either as drunk and disorderly, or drunk and incapable—the police classification of such offences. Our contemporary, referring to a return just issued by Hansard, shows that 1213 of these cases occurred between Sunday morning and Monday morning, and 39,103 between Monday morning and the next succeeding Sunday morning. From the much less number of cases occurring on Sunday he infers the efficacy of the legislation which prohibits the sale of drink on Sundays. The grocer's licence still exists, and is the cause of intemperance of an insidious character to a great extent. Still, it is for the press and the pulpit to enlighten communities on this subject. Neither in Scotland nor in England have either of these powers been perfectly free to make effective onslaughts on this vice. Up to very late days, at any rate, there have been men of light and leading in Scotland who could claim membership in clubs where a minimum of ten tumblerfuls had to be drunk at a sitting. What surprise can we feel at vulgar people indulging when such scientific ignorance prevails among the leaders of society? To do the Church of England justice, in all its sections it is doing its share to modify and improve the old and coarse habits of society in this respect. And we

Digitized by Google

believe the same is true in Scotland. But a deeper faith seems to tarry there, if not in the virtue, at least in the harmlessness, of its own favourite whisky. We are not aware of any medical authority for the belief that Scotch tissues are proof against Scotch drink. And the great authority of Sir Walter Scott himself for moderation is not to be forgotten. It is more than sixty years since he said, "Wine I seldom use when alone, and use instead a little spirit and water. I have of late diminished the quantity, for fear of a weakness inductive to a diabetes, which broke up my father's health, though one of the most temperate men who ever lived."

ANTHRAX.

AT the recent Gloucestershire Quarter Sessions the prevalence of swine fever and anthrax in the county was reported. The first outbreak of anthrax was at Thornbury; and at Poulton, near Fairford, where it had since appeared, it has unfortunately been accompanied by loss of life. A man who skinned the carcase of a bull which had died of anthrax was taken suddenly ill and died. Sir John Dorington, M.P., said that at Thornbury the entrails of one of the animals that died of anthrax were given to half-a-dozen pigs, and they all died. At Poulton ferrets were similarly fed, and they died. He wisely drew attention to the highly contagious nature of the disease, and the liability of infection by persons attending affected animals if they had any cuts or scratches on the hands. In connexion with this subject we learn of a death from woolsorters' disease at Keighley. The case was that of a labourer fifty years of age engaged at Dalton Mills, who was attacked on June 17th and died on the 23rd. In this case a malignant pustule appeared on the neck. The post-mortem examination was made by Dr. Dobie, with Drs. Hime, Rabagliati, and Bell, of Bradford, and they were unanimously of opinion that the case was one of woolsorters' disease. It was given in evidence at the inquest that during the day on which the man was taken ill he had been engaged with five or six others in removing wool from bales of English and Persian wool. No special precautions were taken to prevent infection, but it was pointed out that hitherto Persian wool had not been regarded as dangerous. The firm promised, however, to adopt the Bradford prophylactic regulations in future.

MATERIA MEDICA IN CHINA.

WE have received from Hong-Kong the first number of a book which promises to be of unusual interest—viz., "Notes on Chinese Materia Medica," conducted by Charles Ford, F.L.S., Ho Kai, M.B., and William E. Crow, M.P.S. The authors draw attention to the want of accessible information concerning Chinese drugs, and hope their labours may promote the identification of many of them. They make graceful reference to the work of others in the same direction, and, indeed, intend to stamp the identity of the plants dealt with by affixing the number originally awarded to the Pên ts'ao drugs by the late Daniel Hanbury. The present number deals mainly with gelsemium elegans, a drug which owes its importance to its frequent employment in criminal poisoning, suicidal or homicidal. After a very full description of the plant and its habitat, the root which is used in medicine is dealt with more particularly. It is stated to yield an alkaloid, belonging to the strychnine or tetanus-producing group. This alkaloid is said not to be associated with *gelseminic acid*, and not to bear the action of sulphuric acid at a temperature of 100° C. Although the drug is never used internally, being employed ordinarily only in the treatment of boils, ulcers, ringworm, and leprosy, yet its powerful properties appear to be widely recognised, numerous cases of criminal poisoning having occurred in Hong-Kong within the last few years. In some brief remarks upon a form of strychnos, it is curious to note that the Chinese appear to be unaware of the poisonous action of these seeds. Judged from this first fasciculus, the work promises in its complete form to be an interesting and valuable epitome of Chinese materia medica. The authors express their readiness to send specimens of drugs of doubtful origin to anyone desirous of prosecuting inquiries.

THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

IN his recent address as retiring President of the above Society, Dr. F. H. Alderson, after alluding to the satisfactory state of the Society, said that perhaps to the general practitioner the two most important events of the year were the accomplished fact of the direct representation of the profession in the Medical Council, and the inquiry initiated by Sir Andrew Clark as to the best means of providing medical attendance for the sick poor on a provident basis. One important result of direct representation had been to raise the question of limited pupilage, for Dr. Glover moved and carried at the very first meeting of the Council a resolution for a committee to consider the best means of increasing the practical element in medical education. Dr. Alderson attached much importance to this revival of pupilage, in a limited form, as a means of increasing not only practical knowledge, but good medical conduct and respect for the honourable methods of practice. He concluded his address by several suggestions bearing on pupilage, hospitals, the relation of hospitals to general practitioners, and of the latter to consulting and hospital surgeons and physicians. Finally, he urged the establishment of a night medical service for London and other large towns as in Paris.

MIDDLESEX HOSPITAL.

WE are glad to notice that a concert, under the immediate patronage of Her Majesty the Queen and many members of the Royal Family, is to be given on Wednesday next at the Royal Albert Hall in aid of the funds of Middlesex Hospital. The "Golden Legend" will be performed. Sir Arthur Sullivan will conduct his own work, and Madame Albani, Madame Patey, Mr. Edward Lloyd, and Signor Foli will take the principal parts, and will be supported by the choir of the Albert Hall Choral Society. An influential Ladies' Committee has been energetically working for its success, and has already obtained for it much support. We hear that there is a good demand for tickets, and it is to be hoped that a satisfactory balance will be handed over to the treasurers of the hospital.

PATENT MEDICINES.

THE enormous public importance of "patent medicines" can be estimated from the fact that during the financial year which has recently ended a sum of no less than £179,071 was contributed as stamp or label duty. Regarded simply as a measure of public credulity, these figures are sufficiently surprising; but a more serious aspect of the case remains—the question of the morality of the stamp duty. To the ignorant section of the public the stamp is generally supposed to imply some sort of official guarantee of the excellence, or at least the harmlessness, of the preparation so mystically enclosed; the consequence is, as the records of many coroners' inquiries show, that mistakes and misadventures are of frequent occurrence. Considering the great increase in the use of patent medicines, it is surely time that the stamp should be no longer used to cloak many substances which without it could only be dispensed in coloured bottles as poisons, with the usual restrictions regarding

Digitized by Google

their sale. At present the only real information conveyed by the stamp is the strict compliance with the regulations affecting the sale of proprietary drugs; in other words, it is simply the indication of a commercial speculation, in which the Government goes shares with adventurous advertisers.

ARMY SURGEONS.

IN the House of Commons, on Monday last, Dr. Farquharson asked a question respecting a grievance of the Army Medical Officers to which we have repeatedly called attention—the difference of the system adopted with regard to the dating of the commissions in the Army, Navy, and Indian Medical Services (*vide* THE LANCET, Sept. 18th, Dec. 25th, 1886). It is one of the real grievances of the department; it is obviously unjust that entering the service under exactly the same conditions as regards qualifications and examination, the army medical officers should, during the whole period of their executive service, be junior to those of the Indian and Naval Services, who gained their appointments at the same time, and have certainly no equitable claim to obtain this precedence. We are far from satisfied with the answer given by Mr. Brodrick. Admitting the facts, he said that "whether the army surgeons experience any practical inconvenience from the antedate given to Indian and naval surgeons may be doubted." This is a point upon which the Financial Under-Secretary has no right to be in doubt. He has it in his power to obtain authoritative information from the head of the department, and he is bound in justice to the officers to use every means to remove what is felt and acknowledged to be a very real grievance. Mr. Brodrick gave it as his opinion "that the best way to remove the anomaly would be for the Admiralty and the India Office to follow, in future appointments, the practice of the War Office." This may be an exceedingly convenient way of answering a question, but it does not relieve the War Minister from the duty of seeing that officers are not treated with injustice. What steps have been taken by the War Office to rectify this "anomaly"? Have any suggestions been made to the heads of the other two services on the subject? and with what result? If not, or if they have been made without success, what does the Secretary of State propose to do to obtain just treatment for the army medical officers? We trust that Mr. Stanhope will repudiate the shelter of "doubt" put forward by Mr. Brodrick, and that he will ascertain through the Director-General the actual state of the case, and will adopt efficient measures to remedy a manifest injustice inflicted upon officers of a branch of that service of which he is the responsible head.

THE PUBLIC VACCINATOR FOR CARDIFF.

WE can feel much sympathy for local authorities who are jealous of the health reputation of their town, and who endeavour to maintain this reputation by active sanitary administration. We fail to understand, however, the action of the Vaccination Committee of the Cardiff Board of Guardians, who are reported in a local journal to have recommended that the public vaccinator for Cardiff, Mr. [redacted], should be deprived of his office because he has [redacted] a member of the Town Council with information [redacted] the existence of certain cases of small-pox in [redacted]. Statements, we understand, had recently been [redacted] a meeting of the Health Committee as to the [redacted] of Cardiff from small-pox, and their accuracy being [redacted] by some members of the corporation, one of their [redacted] sought further information from the public vac- [redacted] Whatever view the Vaccination Committee may [redacted] the propriety of the action of this gentleman in [redacted] to a member of the Corporation knowledge [redacted] we hold very strongly that there [redacted] to the existence of disease. If the guardians adopt the recommendation of their committee, Cardiff will be exposed to the charge of endeavouring to maintain its character for salubrity by methods which will not meet with public approval, and which will, indeed, lead the public to regard with distrust any statements that may be made in the future on this subject. When sanitary administration is effective, and when town authorities are honestly engaged in the duty of preventing disease, a plain statement of facts cannot possibly do injury. We believe, moreover, that were local authorities to publish every week a statistical return of the cases of infectious disease which have occurred during such period, considerable aid would be rendered to the progress of health administration in the country, and they would not suffer by such publicity; they would, indeed, be able to claim that they had nothing to conceal, and would thereby win public confidence. If we understand the Cardiff incident aright, this view is not sufficiently understood in that town, and we shall watch with some interest the action of the Board of Guardians in dealing with the report of their committee. Nothing can be more damaging to a town than that its authorities should be credited with the desire to conceal the existence of disease, yet the story published by a local journal points to this conclusion. Certainly the facts recorded there require explanation.

A CONSUMPTION HOSPITAL FOR EDINBURGH.

WE gather from articles in the *Scotsman* that there is some difference of opinion in Edinburgh as to the best use of a Jubilee Fund, which was to be devoted in one way or another for the benefit of consumptive patients. The writer of the articles pleads strongly for a consumption hospital for Edinburgh similar to those of London. A hospital, however, is but a poor part of the remedy for the misery of consumptive disease. We urgently need legislation to diminish the risk of certain callings which engender the disease, and to improve the homes of the poor, in which it grows as in a hot-bed. We also require a large charitable fund for the good of those threatened with, rather than actually ill of, phthisis. A timely voyage or change of air would do more for such cases than any mere hospital treatment, and is a form of charity that would be worthy of the Jubilee Year of Queen Victoria.

CHOLERA IN ITALY.

IN March last we drew attention to the existence of cholera at Catania, in Sicily. The outbreak was not severe, and at Rome its identity with the Asiatic disease was held in some doubt. From that date to the present time no further cholera intelligence has been received from Italy; but now comes news of a serious outbreak at Rocella on the Calabrian coast, and within a suspiciously easy distance of Sicily. Some panic has ensued, the inhabitants fleeing from the affected locality; and, according to a report dating from Naples on the 3rd inst., seventeen cases and nine deaths had already occurred. The latest news from Rome, however, is to the effect that the Calabrian disease, though of a suspicious character, is not cholera.

MILK SCARLATINA.

THE Royal Agricultural Society have been informed by the Privy Council that the inquiry concerning the infection of milk through an eruptive disease of the cow is now being prosecuted, and it is proposed that it should include all the questions which have been raised in Dr. Klein's reports and papers, and the Society are further told that they might assist by urging farmers to examine their stock frequently, and at once to give notice to the Agricultural Department of the existence of any eruption on the teats or udders of

Digitized by Google

cows. We are glad to see that the subject is to be dealt with in a comprehensive manner; but probably the Hendon disease will only be able to be identified when further outbreaks of scarlatina due to milk infection have enabled its clinical characters to be better appreciated. When opportunity occurs, it is to be hoped that accurate drawings will be made of the affected udders and circulated amongst farmers. As yet the official reports on Dr. Klein's more recent work as to the relation between the cow disease and human scarlet fever have not been published, but we may anticipate they will appear in the next volume of the report of the Medical Officer of the Local Government Board.

MR. SPURGEON ON THE GROCERS' LICENSING SYSTEM.

MR. SPURGEON is nothing if not severe and sweeping in his denunciation of what he believes to be wrong. We do not sympathise with all his views on matters of social policy, but we believe he is absolutely right about the grocers' licensing system. It is one of the most mischievous of the facilities offered for the growth of the drink vice in this country. Multitudes of otherwise respectable women, in all classes of society, are led to indulge in the pernicious practice of drinking secretly, by the ease with which they can procure spirits and wine and beer while purchasing other household stores at the grocers. A great deal has been done and said with the purpose of inducing the Legislature to abrogate this system of licensing, leaving the sale of intoxicating drinks to the licensed victuallers and wine merchants, from whom what is bought must needs be bought openly; but no argument as yet adduced has been potent enough to counteract influences and to outweigh interests which would be affected by the withdrawal of licences from grocers. Whether further efforts may be successful remains to be seen. We fear they will not.

THE POLLUTION OF THE THAMES.

AT last there is some prospect that the right of local authorities to pollute the Thames will be tested in a court of law. The Staines Local Board have been repeatedly fined for allowing the sewage of their town to enter the river, but no other result has followed. Their action, which has thus been condemned, has been continued without intermission. The Thames conservators have now determined to prosecute the Staines Board, and the grand jury of the county of Middlesex have been summoned to the Lord Chief Justice's Court for this purpose, and have returned a true bill against this Board. These proceedings have not been taken too soon. The dangers to London water drinkers from the pollution of the Thames is a very definite one, and has been frequently insisted upon by ourselves. The issue of the trial which is about to take place will be awaited with some anxiety, for one of two conclusions is obvious—either the condition of the Thames must be improved so as to make it a safe source of supply, or a fresh source must be found.

NOTIFICATION OF INFECTIOUS DISEASES.

IN his annual report on the sanitary condition of Cardiff during 1886, Dr. Paine suggests the adoption of the dual system of notification of infectious diseases. He would make it a compulsory notification on the householder, and leave it as a voluntary one on the part of the medical attendant, who, whenever he notified, should receive a fee for his certificate. Dr. Paine evidently attaches importance to the medical aspect of notification, and he refers especially to the fact that such notification supplies definite information as to the nature of the infectious disease to be dealt with.

THE CROWN PRINCE OF GERMANY.

HIS IMPERIAL HIGHNESS continues to make a steady improvement. We learn from Berlin that the piece last excised by Dr. Morell Mackenzie, and submitted to Professor Virchow, is "shown even more clearly than the one removed by the previous operation to be a hard and composite wart, which had proceeded or grown out of a moderately irritated and thickened surface, while its base has not shown the slightest ground for assuming the existence of a new growth penetrating into the tissue."

THE CAUSE OF PUERPERAL ECLAMPSIA.

IN a recent number of the *American Journal of Obstetrics* (March and April, 1887), Dr. A. F. King enunciates the theory that pressure on the aorta and vena cava inferior, which he believes to be the cause of the renal troubles in pregnancy and labour, are due to the abnormal position of the fœtus in the latter part of pregnancy. This he believes to be normally the "dorso-anterior position of an oblique presentation"—i.e., the head normally lies not in the brim of the pelvis, but in the iliac fossa; in this position the shape of the fœtus is such as to avoid pressure on the great vessels. He does not believe that in primaparæ the head of the child is normally lower at the end of pregnancy than in multiparæ, and attributes its frequent low position to vanity, leading to tight lacing. This pressure on the great vessels leads to pressure in the renal and cerebral arteries, thus accounting for the renal troubles as well as the nervous condition. The paper, which is the result of much thought, fails to convince us, and will probably fail to convince others. It serves to show the unsatisfactory condition of our knowledge on this subject, but, like all thoughtful inquiry, should help, directly or indirectly, to put an end to this ignorance.

PUBLIC SERVANTS AND THE HOT WEATHER.

WE are glad to see that a committee has been formed to raise subscriptions for the purpose of recognising the services of the metropolitan police, "a body of men who, by their steady conduct in the performance of duty, have deserved well of their countrymen," and that it is proposed that such recognition should take the practical form of a seaside convalescent home for the sick and wounded of the police force. It is necessary, however, that those who are in health should also be cared for, and we would suggest to the Commissioner of the Metropolitan Police to follow an excellent example set elsewhere, notably at Brighton, and to allow his constables in this very hot weather to wear white instead of black helmets. It is satisfactory to observe that some of the railway companies now permit their servants to don light comfortable linen jackets in place of their ordinary heavy coats, and that occasionally postmen are to be seen wearing light sun-hats.

A CASE OF TRICHINOSIS IN BRUSSELS.

HITHERTO Belgium has been believed to have been free from trichinosis. A case has, however, recently occurred at the Molenbeek Hospital, and, being reported to the Minister of the Interior, M. Wehenkel was deputed to report on the matter. The patient was a German, and was born in 1811, but had lived in Belgium for many years. He seems never to have complained of rheumatic pains except in 1886, during which year it was remarked that his voice had become altered. He was known to have been very fond of American bacon. The man was admitted into the hospital on the 13th of June with a cyanotic skin, a thready pulse, an inaudible voice, and profuse diarrhœa, from which last he had been suffering for five days. He died the next day. At the necropsy trichinæ were found in all the muscles except

Digitized by Google

the heart. The cysts had some of them undergone calcareous degeneration; others contained living trichinæ. No trichinæ were discovered in the intestinal canal. M. Wehenkel advised that the body should be destroyed either by incineration or by sulphuric acid. Professor Crocq, whose patient the man was, in an instructive clinical lecture on the subject, which is published in *La Presse Médicale Belge*, gives it as his opinion that the infection was due to American bacon eaten at least seven years before the acute symptoms appeared.

HOSPITAL SATURDAY FUND.

MR. ROBERT FREWER, Secretary to the Hospital Saturday Fund, calls our attention to an error in an annotation on this subject in our issue of the 25th ult. The workshop collection, it appears, does not take place until September, and the street collection for the present year has reached nearly £5000, instead of £145, as was stated by us. We were ourselves somewhat puzzled with the figures which came under our notice, but regarded them as an imperfect and temporary statement. We trust that the true report of Hospital Saturday, 1887, will show an eminently satisfactory result.

CHRONIC RHEUMATISM.

THE manifestations of simple chronic rheumatism are not unfrequently throughout a large part of their course more or less limited to one side of the body, and much capital has been made out of this fact in order to support the theory of the nervous origin of many forms of rheumatism. M. Cazalis is one of those who support this theory; he avers that in these cases pulmonary congestions and chronic bronchitis frequently affect only the lung of the same side of the body, the other lung and bronchi remaining free. The right side of the body enjoys the unenviable distinction of being affected more frequently than the left; and, according to M. Collin, rheumatic pleurisy is most common on the right side. M. Cazalis finds support for his contention in the greater frequency of deformity and deviation outwards of the right great toe in the cases in question; and also in the dextral hemi-laterality of megrim, chorea, and hysteria, due to arthritic causes.

MODERN FASHIONS.

POPPY RED, porcelain blue, royal blue, and mauve are, we are told, to be the favourite tints at French, and therefore at English, watering-places during the coming bathing season. Pink is discarded in favour of heliotrope, although the latter colour fades directly in the sea air, and assumes a dirty-brownish hue. Those who have weak eyes and yet sit much in the open air may remember that neutral and dull tints are less irritating than bright-red and saturated blue. The injurious effect of scarlet on the eye is demonstrated by the discomfort and irritation felt by those who are engaged for many hours daily in making soldiers' clothes. In most instances, however, it is not the light that comes from above that harms—nature has provided us in that respect with quite sufficient protection in the eyelids—but it is the glare that is reflected in bright sunlight from sea and land, as is abundantly shown by snow blindness.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

The deaths of the following foreign medical and scientific men are announced:—M. le Dr. Liouville, Deputy for the Oise, and *professeur agrégé* of the Paris Medical Faculty, from cardiac disease, at the age of forty-nine.—M. Caytan, [illegible], the oldest and most respected of the medical practitioners of Antwerp.

A GUNSHOT WOUND OF THE CLAVICLE.

DR. MANUEL S. SORIANO has recently brought before the notice of the Mexican Academy of Medicine an interesting specimen in the pathological museum under his charge of an old gunshot wound, where the ball penetrated the substance of the left clavicle and fractured the bone, but ensconced itself behind it, and, with the callus thrown out, forming a perfectly rigid structure, though some deformity remained; the man, however, lived for twenty years, and then merely applied for advice on account of some fistulous openings which had presented themselves. The surgeon who saw him proceeded to resect the bone, but the patient died from septicæmia in a few days' time. At the necropsy the bullet was found embedded in the bone.

LEAD POISONING FROM HOME-MADE WINES.

LAST year Dr. Donald Campbell of Calne brought under notice in an excellent report the fact that lead poisoning in and about Calne was being largely brought about by the use of home-made wines, which during the process of fermentation took up the lead contained in the glaze with which the local earthenware pans were coated. The publicity given to this method by which lead poisoning can be brought about does not appear to have sufficed to stop the manufacture of these wines in pans lined with a glaze containing lead, for, according to the recently issued report on the Upton-on-Severn rural district, Mr. J. S. Cowley finds the same results in progress there, the wine in question being mainly a home-made plum wine.

DYSPEPTIC VISUAL TROUBLES.

SUCH symptoms as tenderness of the globe of the eye brought on by the act of accommodation, associated with vertiginous attacks and intellectual torpor, or with scintillating scotoma, hemiopia, and photopsia, or even polyopia, sometimes supervene after meals, and have been ascribed to auto-intoxication by peptones the result of defective action of the liver; but these symptoms are far more common in neuropathic subjects, and the question must remain unsettled whether the dyspepsia may not be of as neurotic an origin as the other disorders, which are clearly of nervous kind.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—The Veterinary College was on the 29th ult. officially proclaimed by Dr. Lucius, the Minister of Agriculture, to have been raised to the rank of a Hochschule or University. The first rector is Professor Müller.

Brussels.—M. le Prof. Pigeolet has been elected President and M. le Prof. Kufferath Secretary of the Medical Faculty.

Cracow.—Dr. Rudolf Trzebitzky has been recognised as *privat docent* in Surgery.

Innsbruck.—The Professorship of Midwifery, vacant by the translation of Professor Schauta to Prague, has been filled by the appointment of Dr. Emil Ehrendorfer, *privat docent* in Vienna.

Lyons.—M. Albertin has been appointed Prosector for three years.

Montpellier.—A valuable library, together with the sum of 15,000 francs, has just been bequeathed to the Medical School by M. Bouisson, who desires that the monetary legacy shall be employed in erecting a suitable building for the reception of the volumes and for the expenses of printing a catalogue. In addition to all this, M. Bouisson has left 100,000 francs to found five annual prizes to be called by his name.

Munich.—The municipal authorities have promised to grant a site worth £15,000 between Findlingsstrasse and

Digitized by Google

Krankenhausstrasse for a new surgical clinic as soon as the Government is prepared to build. It is estimated that the cost will amount to more than £30,000.

Poitiers.—M. Buffet-Delmas has been appointed for a period of nine years Supernumerary Professor of Anatomy and Physiology.

Prague.—Two schools for midwives are about to be established. The instruction to be given in German and Bohemian respectively.

Vienna.—Dr. Sigmund Lustgarten has been recognised as *privat docent* in Dermatology.

Würzburg.—July 6th is being celebrated by Prof. Kölliker as the seventieth anniversary of his birth, and as marking the completion of forty years' occupancy of the chair of Anatomy.

THE prizes at St. Mary's Hospital Medical School will be distributed by Sir Edward Sieveking on Thursday, July 21st, at 3 P.M. At the same time it is proposed to present Sir Edward Sieveking with a testimonial (on his retirement as senior physician), to mark the high esteem in which he is held, and in recognition of the great service he has rendered to the hospital and school. Subscriptions to this fund should be sent to the dean.

DR. VINCENZO SCIALPI of Taranto has issued a pamphlet dealing with the symptoms, prognosis, causes, and cure of cholera. Details as to the latter he reserves, desiring to submit them, for the purposes of securing an award, to the Italian Medical and Chirurgical Academy. Dr. Scialpi had experience of cholera both in 1854 and in 1884, but his views as to the causation of the disease are not those current in this country.

DR. ANTHONY COLLING BROWNLESS was on April 30th presented with an illuminated address from the office staff of the University of Melbourne, congratulating him on his accession to the honourable and responsible post of Chancellor of that institution. Dr. Brownless has for seven years acted as Vice-Chancellor.

IT is understood, states the *Daily News*, that the Queen has intimated her intention to confer a baronetcy on the Dublin physicians, Dr. J. T. Banks and Dr. H. H. Head, respectively.

THE governing body of the Bristol Royal Infirmary has resolved to elect, for the first time in the annals of the institution, an obstetric physician.

SEVERAL soldiers at the Curragh camp have during the recent hot weather died from sunstroke.

DR. HENRY GERVIS has resigned his post as Obstetric Physician to St. Thomas's Hospital.

PRESENTATIONS.—H. D. King, M.D., M.A., B.Sc. Edin., of the Limes, Linton, on the occasion of his leaving that town to settle in Sudbury, was presented by his friends and patients in the neighbourhood with an illuminated address and a silver salver, an antique tortoiseshell tea-caddy being at the same time presented to Mrs. King, and a spade guinea to the doctor's son.—Dr. Octavius Jepson has been presented with a handsome marble clock and vases by the officials of the City of London Lunatic Asylum, Stone, Dartford, on the occasion of his resigning the post of medical superintendent, which he has held for the past twenty-three years.

MEDICAL MAGISTRATE. — Mr. Charles J. Jones, M.R.C.S. &c., Tonypandy, has been placed on the Commission of the Peace for the County of Glamorgan.

REPORT
OF
The Lancet Commission
ON THE
POLLUTION OF THE THAMES AT THE HENLEY REGATTA, 1887.

THE Henley Regatta proved this year a brilliant success. The presence of the Prince and Princess of Wales, together with several other members of the Royal Family, helped to attract a highly fashionable throng. The fact that the aquatic carnival followed so closely on the celebration of the Jubilee imparted to the fête an aspect of exceptional rejoicing. Extensive illuminations, both on the shore and on the water, further contributed to attract increasing thousands of visitors. The weather also was remarkably fine—indeed perhaps too fine, for the heat was somewhat overpowering; yet behind all this glitter and gaiety lurked a cruel suspicion that evil consequences might possibly arise. The long-continued drought has made the water of the Thames fall very low. It is therefore more than ever necessary that the reduced volume of water should be kept exceptionally clean. This we had hoped would be done by the enforcement of the new bye-laws rendering it illegal for house boats and steam launches to drain direct into the Thames. It has, however, already been explained that these bye-laws were not gazetted before the Saturday previously to the race. This only allowed the following Monday and Tuesday for the carrying out of the new regulations. Of course nothing was done. Indeed the numerous occupants of the house boats whom we questioned were not even aware that any alteration had been made. So the dangers of last year have had to be encountered again this season. In the present instance the risk is aggravated by the fact that the water is much lower; on the other hand, there is as yet no extensive cholera epidemic in Europe. At the time of the last Henley Regatta, it will be remembered, cholera was very prevalent in Italy, and it was quite possible that some travellers from the south—persons who, for instance, had wintered in Italy and in an incipient stage of the disease—might then have returned to England in order to be present during the regatta. The patients would probably have resorted to one of the closets on a house boat before the true nature of their complaint was ascertained. Thus the choleraic dejections would have been drained into the drinking water used in London. How far the specific germ might have grown and multiplied to a sufficient extent to produce an epidemic in London we are unable to say. The consequences, however, would be so appalling that the risk, if ever so slight, should, at any cost, be avoided. Nevertheless, this has not yet been done.

On the day before the regatta we proceeded to Henley, to investigate the present state of affairs. A great number of house boats and launches had already assembled. On the course we counted sixty-six house boats and thirty-nine steam launches; but there were some more on the other side of the bridge. It was no easy matter to ascertain the condition of the house boats. In several instances the occupiers or owners were absent; in other cases there were so many ladies on board that we were obliged to postpone our questions as to the drainage. Nevertheless, we succeeded in obtaining information on a sufficiently large scale to arrive at a definite conclusion. We found that on four boats there were earth-closets. Two boats had been altered since last year, probably in anticipation of the new laws. The other two boats were newly built, had not been on the water before, and were therefore free from the error of construction of the older craft. On the other hand, we found eighteen house boats with closets on board that drained direct into the water. The occupier of another boat refused to answer our questions, so we may fairly conclude that in this case also the drainage was conducted direct into the water. Thus, of the twenty-three house boats we were able to visit, there were not more

Digitized by Google

than four that possessed earth-closets. Alteration in view of the new law had only been made in two instances, and in eighteen cases drainage into the Thames was admitted. We may therefore conclude that the great majority of the house boats still drain into the water, and the same may be said of those among the launches that possess closets. Among the boats draining into the Thames must be specially noticed the starting boat. This is an exceptionally large craft. It contains saloons and a large upper deck, entirely covered with chairs, and each seat was let for the modest fee of five shillings. At least a hundred persons must have gone on board this boat; and all had access to the closet that communicated directly with the drinking water of London. That the Thames Conservancy could not apply the new law to all the house boats in the two days it possessed for action we readily admit. But the boat on which the committee meets, and which is moored opposite the winning post, is so much of a public institution that here, at least, an earth-closet could have been introduced within the two days. This boat was the headquarters of the Thames Conservancy officials during the race. From this point they started to clear the race-course; here they returned immediately the race was over. A few words, a little gentle pressure, would have sufficed to remove the scandal, instead of allowing the boat of all others, which was the most seen, the most frequented, to remain, as in times gone by, a source of infection to all London.

The Thames Conservators, acting according to the suggestions we threw out last year, have, however, effected one notable improvement. They have brought down two scavenger boats which go up and down the Henley race-course late in the evening and early in the morning. All the refuse from the house boats and launches, together with the soil from the few earth-closets that exist, are collected by these floating scavengers and brought to shore at Henley. The carts belonging to the Henley Local Board remove the same to a shoot situated about a mile out of the town. While we were at Henley some complaints were made concerning the landing of this refuse, and perhaps a more appropriate and solitary spot might have been selected for this somewhat unpleasant operation. Not a few persons connected with house boats also expressed strong opinions against the earth-closets, a remedy which they qualified as worse than the evil it is sought to cure. This, however, is evidently a partial statement. An earth-closet, if properly managed, would not cause any nuisance whatever; and, even if it does produce some slight unpleasantness, this would only affect the occupants of the house boats, whereas draining into the Thames compromises the interests of all London. No one is obliged to live in a house boat, but several millions of people find it necessary to live in London.

When the races were over we inspected the river, looking carefully between the house boats and the various creeks, where the refuse generally accumulates. The result was eminently satisfactory. Up to Friday evening, in any case, the scavenger boats had done their work well. Certainly there was a great deal of green stuff floating on the surface of the water, but on examination it proved to be, for the most part, the vegetation of the Thames itself broken up by the many boats collected within close compass during the last few days. The proportion of cabbage stumps, salad leaves, and other edible vegetables was very small. There was a formidable array of corks and empty bottles floating and jostling together in commemoration of recent rejoicing; but we failed to detect the offal, the fish-bones, the pieces of bad meat, the stale fruit, the lobster shells, and the dead fish noted last year. Even faded nosegays seem for the most part to have been reserved for the scavenger boats, and were no longer allowed to float down the Thames as melancholy mementos of forgotten gallantry. There were, however, a large number of pieces of bread, perhaps thrown in by beggars, who do not approve of relief given in kind. It is not yet known how much refuse has been removed by the scavenger boats, but to judge from the improved aspect of the river, the quantity must have been considerable.

These are notable improvements, though the worse danger still remains; but we are assured by the Thames Conservators that they will carry into effect the new bye-law suppressing all closets that drain into the river. Let us hope that not a day will be lost in applying the new regulations. Though the house boats are no longer gathered together in such large numbers on one spot, they are still, for the most part, inhabited, and the pollution of the river therefore continues. Further, the scavenger boats will not follow the house boats as they leave Henley. There is nothing to prevent the occupants of the latter from resuming the practice of throwing offal and other refuse into the water, unless it be the knowledge that the new bye-law applies to all offensive matter as well as to sewage. The circular drawn up by the Thames Conservancy to this effect should therefore be distributed without a moment's loss of time to the occupants as well as the owners of the house boats, and a conviction obtained for the very first offence proved. The Thames Conservancy have always protested that they did not create the grievance, that they were most anxious to remove all cause of complaint, if the law would only empower them to act. They now possess the necessary power, and it is to the interest of every inhabitant of London that they should protect the water we drink from daily, hourly contamination. The great majority of house boats and steam launches floating about on the Thames above the intake of the London water supply still drain into the river. The weather is hot; this is the season for epidemic diseases; not a moment must be lost to put an end to the danger we have often denounced, and, we trust, not in vain.

Pharmacology and Therapeutics.

WARNINGS ABOUT THE USE OF ACETANILIDE.

Two articles have recently appeared in the Hungarian medical journal *Gyógyázat*, in which the profession is warned that acetanilide, or antifebrin as it is called, though it is not without value, is an uncertain, and indeed a dangerous, antipyretic. Dr. Géza Dulácksha finds, after giving the drug a prolonged trial in the hospital, that small doses may bring down fever, but that in some cases even three-grain doses produce violent sweats, prostration, and hæmorrhage or cyanosis. It does not appear to him to exert any favourable action on the course of the disease itself, being thus inferior to salicin, resorcin, and ichthyol. If given at all in fever, its action requires to be very carefully watched. In certain neuroses, however, Dr. Dulácksha has found it very useful, and as the doses required were smaller, he is disposed to recommend its employment in such cases, as it appears to be free from danger. In a case of severe trigeminal neuralgia, in which quinine, gelseminum, and morphia had produced but little improvement, three grains of acetanilide were given night and morning without effect; seven grains and a half were then ordered, divided into ten powders, one to be taken every two hours. This produced a great improvement, and after ten days of this treatment the cure was complete. No unpleasant effects beyond some nocturnal perspiration showed themselves. Two other cases, where severe pain was associated with meningo-myelitis and syphilitic tabes respectively, which had been treated in various ways unsuccessfully, were greatly benefited by acetanilide, no unpleasant effects being produced. Dr. Biro gave acetanilide in eighteen cases of various kinds including typhoid, croupous pneumonia, pleurisy, polyarthritis, tuberculosis, and phthisis, in doses varying from a grain and a half to forty-five grains per diem, and was much struck with the uncertainty of its action, an effect being sometimes produced by a grain and a half, while at others ten or eleven grains had no effect at all. Most of the patients complained of chilliness, while cyanosis and irregularity of pulse occurred in several cases. In one case, where seven grains and a half had been taken, there was a severe rigor followed by cyanosis, sweating, and an irregular, thready pulse, the symptoms being so alarming that recourse was had to brandy and hypodermic injections of ether. In another case, in which acetanilide had been given for eleven days, similar symptoms presented themselves, together with clonic spasm of the lower extremities, reminding one of the symptoms in anilin poisoning. Altogether, Dr. Biro thinks that the evil effects of acetanilide are so great that it cannot be recommended for general adoption.

ANTIPYRIN.

Two Scandinavian physicians have recently written on the use of antipyrin, the apyretic properties of which they unreservedly admit to be the rule. Some exceptions, however, were observed. Thus Dr. Wetterdal of Upsala found in one case a rise of temperature during the first hour after

Digitized by Google

a thirty-grain dose of more than 1° F. Rigor and collapse never occurred in any of his cases. Copious sweating, however, was observed at times, over which atropine exerted no control. A rash with bluish-red spots on the face, as described by Wising, was also occasionally noticed. In some cases cinchona was advantageously combined with antipyrin. Dr. Laache, who made a special study of the action of antipyrin in phthisis, found that, though as a rule it brought down the hectic very satisfactorily, in one instance it produced, at first at least, a contrary effect, the temperature rising very markedly after a thirty-grain dose. It afterwards fell gradually, reaching a point decidedly below the normal. Simultaneously with the rise a rash appeared, and the patient complained of a burning sensation in the mouth and eyes and along the œsophagus. Curiously enough, the patient had previously taken antipyrin for a longer period without having experienced any unpleasant effects. The sample could not well have contained any poisonous admixture, as other patients took it with impunity.

INGLUVIN.

Dr. Paul Mohr of Cologne, writing in the *Allgemeine Medicinische Central-Zeitung*, mentions some cases in which he found this preparation give good results when all other treatment had failed. In a very troublesome case of tabes mesenterica, in which nourishment of every description was invariably vomited, the very first dose produced a marked effect. About four grains were ordered to be dissolved in liquid nourishment three times a day, and in a few days' time food of various descriptions could be retained without difficulty. In two other cases somewhat larger does—i.e., five grains four times a day—were employed with equal success. One was a case of delirium tremens, and the other one of severe dyspepsia associated with entozoa, the patient being utterly unable to retain the nauseous medicine necessary for the destruction of the worm. By means of ingluvin this condition was remedied, and the entozoon (a tænia solium) got rid of, a complete cure resulting.

NEUTRAL HYDROCHLORATE OF QUININE.

Neutral hydrochlorate of quinine is soluble in its own weight of water, and therefore possesses many advantages over its basic ally, which dissolves in twenty-two times its weight of water. M. Clermont prepares the neutral salt by mixing one equivalent of neutral sulphate of quinine (548 grammes) with two equivalents of dry chloride of barium (208 grammes), after having dissolved them in a sufficient quantity of water; the moisture is then evaporated below 100° C., and the neutral hydrochlorate is left behind. A solution of this ought not to have a caustic taste.

SANTONIN.

The chemical constitution and the physiological action of this anthelmintic have just been made the theme of fresh investigation by Coppola and other Italian pharmacists. Their results have been embodied in three separate papers submitted a month ago to the Accademia dei Lincei, and will shortly appear in the "Atti" of that society. Tommasi-Crudeli contributes a note on these results.

TREATMENT OF TOOTHACHE DUE TO DENTAL CARIES.

Dr. Popoff, writing in the *Russkaya Meditsina*, states that he has succeeded in relieving toothache caused by caries of the teeth by making the patient rinse the mouth every half-hour with a dessertspoonful of a 20 per cent. solution of permanganate of potash, taking care to hold the liquid in the mouth for some minutes.

HEALTH OF THE IMPERIAL JAPANESE NAVY.

THE special reports upon the improvement in the scale of diet in the Japanese navy for the years 1883 and 1884 afford some very interesting information bearing on the influence of diet upon health, and especially upon the prevalence of kakké (*beri-beri*) in that service. From a table in the second report it appears that the deaths, on the average of the six years 1878-83, in a force of 4887, amounted to 17·29 per 1000, and of these 8·39 per 1000 were from kakké. The Director-General of the Medical Service, Takaki Kanehiro, F.R.C.S. Eng., being struck with this high rate as compared with that of European and American navies, instituted an inquiry into the causes of this fatal disease, and came to the conclusion that it depended, in great measure at least, on the quality of the food supplied to the men. A scheme for the improvement of their diet was prepared, and came into operation in 1884. The practical result was an immediate reduction in the general death-rate, which, on the average of the two years 1884-85, was only 7·49. This great decrease was chiefly in the deaths from kakké, which during the first period averaged 8·39, and in the last two years were only 0·64 per 1000. But the beneficial results of the increased and improved scale of diet were not confined to the reduction of the death-rate, they are manifest also in the cases treated. The returns do not give the number of these prior to 1883, but in that year they are stated to have been 3235 per 1000 of the strength; in 1884 they were reduced to 1864, and in 1885 to 992.[1] These ratios somewhat overstate the amount of sickness, as the compiler of the returns has fallen into the error of adding the number on the sick list at the beginning of the year to the cases orginating during the year; but for the purposes of comparison they are sufficiently correct. The mean daily sick per 1000 of strength in 1883 was 121, in 1884 it was 84·5, and in 1885 it was still further reduced to 52·25. From 1878 to 1883 the cases of kakké averaged 324 per 1000 of strength annually, in 1884 they were 137, and in 1885 only 5·9; but even this does not fully represent the gain, for of the 5·9 no less than 4·6 were cases under treatment at the beginning of the year; those occurring during the year, therefore, were only in the proportion of 1·3 per 1000 of strength. The improvement in health, however, as shown by the reduction of cases, was by no means confined to kakké. It was very marked in diseases of the digestive and respiratory systems (the classes giving rise to the highest ratios of cases), and diseases of the eyes were reduced to one-half the previous amount. In 1883 the average daily amount of food issued to the petty officers and seamen was 50·37 oz., of which 25·78 were rice, 9·56 vegetables, 4·85 fish, and 2·18 meat. In 1884 the total amount was increased to 78·38 oz.: the rice to 32·16, vegetables to 12·41, fish to 6·56, and meat to 8·02; and milk and tea were added. In 1885 a further modification took place, the total amount being raised to 85·81 oz.; the rice was reduced to 18·45 oz., 8·85 oz. of wheat and 8·48 oz. of bread being substituted; meat and fish remained nearly the same, but vegetables were increased to 17·89 oz. and the milk was raised to about a pint and a quarter daily, with some modifications in subsidiary articles of the ration. It would be interesting to know whether the army was dieted on the same meagre scale as the navy, and whether the same improvements were introduced into it with similar results. It is very satisfactory to find the medical officers of the Japanese navy devoting so much attention to the health conditions of the men entrusted to their care, and following up the results of their investigations with so much success. It would be a great advantage in these reports if the numbers who died or have been invalided from each class of diseases were given in the tables, instead of merely the ratio per 100 of cases, as it would render the data much more available for purposes of comparison. In the second report—that for 1885—the summary of the report on the health of the English navy has been reprinted from our columns, to serve as a standard of comparison for the Japanese navy.

In the Chinese man-of-war now lying in the Tyne it appears that several cases of kakké occurred during the voyage to England, of which one died in the Red Sea, and another when passing through the Suez Canal. When the ship arrived in the Tyne there were fifteen or sixteen cases on board, of which three were sent to the Newcastle Infirmary, where two of them died, and a third death occurred on board the ship. As the men had a great objection to being sent to the hospital, Dr. Slater was engaged to attend the cases, and so far all have done well. He is stated to have treated them with nourishing diet, and to have protected them from cold. The success which has attended this appears to bear out the views of the Director-General Takaki Kanehiro as to the cause of the disease in the Japanese navy. It would be interesting to get a detailed statement of the dietary on board the *Yoo Nan* from the time of her leaving China till her arrival in the Tyne.

[1] We find it necessary to call attention to an error in the letterpress of the first report. At page 2 the strength and the number of cases are stated to be for "the 16th year of Meiji" (1883), while the figures quoted are those for the year 1884, as shown in the tables.

HONOUR TO A VETERAN ANATOMIST IN RUSSIA.

ON April 30th, at 11 A.M., the Anatomical Theatre of the Imperial Medico-Chirurgical Academy of St. Petersburg was the scene of a lively and noteworthy gathering of physicians, surgeons, students, and deputies from numerous learned societies, lay and medical, from every part of Russia, to congratulate Professor Wenzel Gruber upon his having held the professorship of practical anatomy for no less a period than twoscore years. During that time Dr. Gruber, besides having instructed, examined, and passed 8000 medical students in practical anatomy, has himself dissected, or superintended the dissection of, upwards of 30,000 bodies. His talents, when Hyrtl's demonstrator in Prague (from 1844 to 1847), having been noticed by the late Prof. Pirogoff, he was invited by the eminent Russian surgeon to St. Petersburg, where he at once received the appointment of Demonstrator of Anatomy at the Imperial Medico-Chirurgical Academy. Gruber, like the late Goodsir of Edinburgh, belongs to a race of students whose sole object in life is the pursuit of their favourite science irrespectively of all difficulties, and to whom worldly pelf presents no attractions. To Gruber the discovery of a new muscle (however insignificant its size), of an anomalous bifurcation of the tiniest arterial twig, of the capricious course of some barely detectable nerve, or of a bursa which had successfully eluded the penetrating eye of former anatomists, afforded more pleasure than would have done the possession of the fattest of the flesh-pots of Egypt. Outspoken and rough at times, Gruber has, however, managed to gain universal respect and love for his honesty, disinterestedness, and kindness of heart. Though apparently indifferent to everything that has not some bearing on anatomy, he is a keen observer of human nature, which he looks at from under thick eyebrows and through large tortoiseshell spectacles. His serious, concentrated look is often lighted up by the pleasantest of smiles, while under an exterior that seems to preclude the idea of a joke or laughter there lurks a fund of dry, at times irrepressible, humour. But to return to the demonstration of which Gruber himself was the subject on April 30th. From various parts of the world there were eighty telegrams sent to the veteran anatomist, while upwards of twenty gorgeously illuminated and bound addresses from different societies congratulated him on the completion of his fortieth year of professorship. A large gold medal, struck in his honour, was presented to him, while a copy of it in silver was struck for and presented to Mrs. Gruber. On one side of the medal are the Christian and family names of Gruber, and below a very good likeness of him; the finely-shaped oval head, the high and full brow, the thick, bushy head of hair, and the rounded and beautifully chiselled chin are admirably portrayed by the sculptor. The reverse of the medal presents, in its centre, the large Roman numerals XL.; below the inscription is 1847—1887; while above is written: "To the teacher of 8000 Russian surgeons." A splendid album, containing upwards of sixty original paintings in oil and water-colours, was presented to him by some of the first artists in Russia. The Emperor created him a Knight of the White Eagle, one of the highest of Russian orders. Indeed, there was no end of telegrams, addresses, memorials, and speeches—all tending to show how deeply respected and beloved Gruber is, alike by colleagues, pupils, and the public in general. So remarkably prolific a writer is Gruber that during forty-three years, the number of his published anatomical memoirs and pamphlets exceeds 540—a proof that the anatomists of a bygone age were generous enough to leave something for their followers to do and discover. Although honoured by the Tsar of Russia, the Minister of War, the Town Council, and literary and artistic societies throughout the country, the embassy of Austria, of which country he is a native and subject, was conspicuous by its absence. Gruber was met and loudly cheered by the young, honest, and lusty voices of hundreds of medical students who waited for him in the corridors of the academy and in the street, and who triumphantly carried him to his home shoulder-high. Gruber thanked them at his door with tears in his eyes, and told them that all he had striven to do during his life was to work and be honest, and if they all did the same he was sure they would succeed in whatever they undertook.

HOSPITAL SUNDAY FUND.

THE following are among the principal amounts received at the Mansion House during the past week on behalf of the Hospital Sunday Fund:—Christ Church, Lancaster-gate, £801 6*s.* 7*d.*; St. Stephen, South Kensington, £193; Portman Chapel, Baker-street, £154; Christ Church, Westminster-road, £57; Eaton Chapel, Eaton-square, £54; St. Alban's, Streatham-park, £67; St. James's, Marylebone, £90; St. Peter's, Vere-street (corrected), £247; St. Gabriel's, Pimlico (corrected), £89; St. Peter's, Eaton-square, £542; St. John's, Wilton-road, £86; Kensington Parish Church, £372; Christ Church, Kensington, £103; St. Stephen's, South Kensington, £193; St. Martin-in-the-Fields, £114; Rosslyn-hill Unitarian Church, Hampstead, £91; Trinity Presbyterian Church, Notting-hill, £62; St. Anne's, Soho, £61; Holy Trinity Chapel of Ease, Wandsworth, £50; St. John the Evangelist, Blackheath, £50; St. James's, Norlands, £63; Holy Trinity, Sydenham (corrected), £123; Wanstead Meeting House, £60; West London Synagogue of British Jews, £232; S. C., £100; St. Mary, Aldermary (corrected), £83; St. John, Paddington, £175; St. Augustine, South Kensington, £85; St. Stephen, Paddington, £100; St. John's-wood Presbyterian Church, £85.

The total amount received on behalf of the fund up to the time of our going to press is rather over £35,000.

VOLUNTEER AMBULANCE INSPECTION.

BY request of the Principal Medical Officer of the Northern Military District, Surgeon Sullivan, M.S., recently made an inspection in camp at Beverley of the bearer company attached to the 2nd Volunteer Battalion, Yorkshire Regiment. The company consisted of fifty non-commissioned officers and men, with three surgeons—viz., Surgeon-Major J. W. Taylor of Scarboro', and Acting Surgeons W. T. Colby of Malton and R. Bruce Low of Helmsley. After a careful inspection of the men, the various movements in stretcher drill were gone through. Twenty-three recruits were then examined in elementary anatomy and surgery, as well as in bandaging and the improved methods of lifting and treating the wounded. The inspection and examination were very thorough, lasting nearly three hours. At its close Surgeon Sullivan spoke highly of the men as to their drill and their knowledge. He said he would send in a very good report, and expressed astonishment at the amount and extent of the proficiency displayed by the bearers.

On Saturday the official inspection of the battalion took place. The inspecting officer, Colonel Barratt, commanding the 19th Regimental District, who has in previous years shown great interest in the ambulance movement, requested the bearers to treat various injuries indicated by himself men from the combatant ranks being supplied for the purpose of illustration. Colonel Barratt questioned the bearers regarding the injuries and their treatment, and afterwards stated that the men fully stood this practical test as to their efficiency. He addressed the bearers, and complimented Surgeon-Major Taylor on the evident proficiency of his men. The bearer company marched past with the battalion at the conclusion of the regimental inspection.

The formation of regimental bearer companies would seem to solve some of the difficulties which many surgeons feel in trying to promote the efficiency of the Volunteer Medical Department. The Volunteer Medical Staff Corps appears to be confined to the large centres of population, and every difficulty seems to be put in the way of getting official recognition. Dr. Taylor's men are all efficient Volunteers as well as bearers. They have passed all their drills, including even musketry. In this way they are doubly efficient, and deserve a double recognition from the military authorities.

PERILS OF SHAVING.—A case of some interest, as suggestive of a danger not generally recognised, has just been heard and decided in the Brighton County Court. A carpenter sued a barber for £5 damages, in consequence of having, as he alleged, contracted a skin disease in the process of undergoing shaving in the shop of the defendant. The decision was in favour of the plaintiff for the amount claimed.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

South Shields Urban District.—In commencing his report in 1886, Dr. Campbell Munro states that the mean death-rate for the borough during the decade which has just closed indicated an annual saving of life amounting to 31 per 10,000 living, as compared with that of the previous decade. During 1886 the death-rate was 20·5 per 1000, and the deaths under one year only amounted to 134 on each 1000 registered births. As regards infectious diseases, the borough isolation hospital did excellent work, no less than 137 cases being admitted, and of these 120 were scarlatina patients. The deaths were only as 1 to every 17·1 cases admitted, a result which is especially satisfactory to Dr. Munro, who has taken upon himself the administrative charge of the institution without remuneration. A considerable part of the year has been devoted to improving the houses of the poor, and Dr. Munro says that the red-tapeism connected with action under McCullagh-Torrens' Acts is such that he will never again resort to them, preferring procedure under Section 97 of the Public Health Act. Satisfactory proceedings were taken in connexion with some Tyne alkali works; and as to milk pollution, such measures as were adopted were aimed, not against retailers, but against the more culpable wholesale dealers, and in every case the action was successful.

Maidstone Urban District.—Mr. M. A. Adams, F.R.C.S., gives the death-rate for the borough as 17·5 per 1000 during 1886. Scarlet fever was somewhat prevalent. Eighty-eight cases came under notice, and of these no less than fifty-eight were received into the new isolation hospital, as to which the report has only praise and satisfaction to record. In like manner 4795 articles were disinfected, this being done free of cost. The need for extending the public water service is shown by the fact that of three samples of well water analysed not one was fit for use, and it is stated that many remain which are highly dangerous. Amongst other improvements effected, we are glad to note the paving of courts and alleys, a proceeding sadly wanted in a vast number of our towns and cities. The year was one without special sanitary incident, but it was marked by steady progress in regard to hygiene.

Marylebone.—Under the name of "Sanitary Chronicles" Mr. Wynter Blyth issues a monthly record of work in this parish, and these supply much of the information which goes to make up the annual record. During 1886 the birth-rate was 25·6, and the death-rate 19·7 per 1000; the mean duration of life for the whole parish being 44·5 years. Considerable improvements as to dwelling accommodation are steadily in progress, artisans' dwellings taking the place of insanitary property. So, also, the leases of great estates are falling in, and this involves extensive repairs or re-erections. Under the Sanitary Acts 2048 orders were issued during the year, and only sixteen owners were summoned for neglect. Amongst tenemented houses, 901 have now been put on the register, and it is believed that but few of the class of houses intended to be dealt with under the law as to houses let in lodgings now remain which are not under control. In 1200 instances extensive improvements in house drainage were effected during the year, and, speaking generally, a large amount of good work was done as the result of nuisance inspection.

Liverpool Urban District.—One of the most satisfactory records contained in Dr. Stopford Taylor's recent annual report is that relating to the mortality from "fever," which since 1866, when typhus was largely prevalent, has fallen with fair annual regularity from 1523 deaths to 198. It is a great pity that the deaths thus tabulated all appear under the meaningless head "fever," except as regards an epidemic of relapsing fever in 1870-72; but this is, perhaps, to some extent, brought about by the terms used in registering deaths. Thus, of the 198 "fever" deaths in 1886, 7 were said to be from gastric fever, 85 from typhoid, 48 from enteric fever, 3 from continued fever, 1 from low fever, 47 from typhus, 3 from fever, and 1 from relapsing fever. As to typhus fever, the disease still clings to Liverpool, and we regret to notice the continued practice of occupying cellar dwellings. Typhus will never be eradicated from Liverpool until much more has been done in improving the dwelling accommodation of the lower classes, and in securing ample means for isolating the disease. The beginning made in the latter direction is excellent in its way, but when we compare Liverpool and its present proposals, and Glasgow with hospital grounds of thirty acres in extent, we have greater hopes for Glasgow in the matter of typhus than we have for Liverpool.

Peterborough Urban District.—Dr. Paley reports that of the cases of enteric fever which were not imported there was a definite local cause ascertainable in nearly every case. Such an experience should lead to increased energy in the matter of inspection, for the value of true sanitary work is mainly shown in the removal of these conditions before, and not after, preventable disease has been brought about. Privy nuisances are especially adverted to, and we have already commented on the question of refuse removal in connexion with the report of the inspector of nuisances. The annual death-rate for 1886 was 17·8 on the population for 1881 and 16·4 on the estimated present population.

Peterborough Rural District.—In this rural area Dr. Paley records a death-rate of 14·5 per 1000, and he strongly endorses the advice given by Mr. Spear of the Local Government Board as to the need for scavenging and refuse removal by the authority themselves in the more populous parts of the district. He says that the question is rather one of organisation than of expense, and only needs the instruction of the authority to carry it into effect.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6114 births and 3207 deaths were registered during the week ending July 2nd. The annual rate of mortality in these towns, which had steadily declined in the preceding five weeks from 20·4 to 17·6, rose again last week to 18·1. During the thirteen weeks ending on the 2nd inst., the death-rate in these towns averaged 19·8 per 1000, and was 1·4 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 9·4 in Derby, 12·5 in Portsmouth, 12·5 in Halifax, and 12·9 in Sunderland. The rates in the other towns ranged upwards to 24·6 in Blackburn, 27·9 in Newcastle-upon-Tyne, 28·1 in Preston, and 29·2 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 489, 501, and 512 in the preceding three weeks, declined again last week to 486, notwithstanding the greater fatality of diarrhœa; they included 156 from measles, 136 from whooping-cough, 110 from diarrhœa, 38 from scarlet fever, 22 from "fever" (principally enteric), 22 from diphtheria, and only two from small-pox. No death from any of these zymotic diseases was registered during the week in Derby or in Halifax; while they caused the greatest mortality in Manchester, Norwich, Birkenhead, and Newcastle-upon-Tyne. The highest death-rates from measles occurred in Oldham, Huddersfield, Manchester, Norwich, Birkenhead, and Newcastle-upon-Tyne; from whooping-cough in Norwich, Sheffield, Liverpool, Blackburn, and Nottingham; and from scarlet fever in Bristol, Birkenhead, and Blackburn. The 22 deaths from diphtheria in the twenty-eight towns included 13 in London and 2 in Manchester. Small-pox caused two deaths in Cardiff, but not one in Greater London or in any of the twenty-six other large provincial towns. The mortality from diarrhœa somewhat exceeded the average for the season. Only one case of small-pox was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease, no new case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding five weeks from 333 to 184, rose again last week to 199, but were 21 below the corrected average. The causes of 65, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Plymouth, Wolverhampton, and Derby. The largest proportions of uncertified deaths were registered in Salford, Sheffield, and Leicester.

Digitized by Google

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·3 and 20·3 per 1000 in the preceding two weeks, declined again to 19·5 in the week ending July 2nd; this rate exceeded by 1·4 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 14·6 and 16·9 in Aberdeen and Edinburgh, to 23·3 in Greenock and 28·2 in Paisley. The 487 deaths in the eight towns last week showed a decrease of 20 from the number in the previous week, and included 43 which were referred to whooping-cough, 18 to diarrhœa, 7 to scarlet fever, 7 to diphtheria, 6 to measles, 3 to "fever" (typhus, enteric, or simple), and one to small-pox; in all, 85 deaths resulted from these principal zymotic diseases, against 90 and 71 in the preceding two weeks. These 85 deaths were equal to an annual rate of 3·4 per 1000, which was 0·7 above the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 48 and 38 in the preceding two weeks, rose again last week to 43, of which 16 occurred in Glasgow, 9 in Edinburgh, 9 in Dundee, and 4 in Greenock. The 18 deaths attributed to diarrhœa, of which 7 were returned in Glasgow and 3 in Dundee, showed an increase upon the numbers in recent weeks, and were 2 above the number in the corresponding week of last year. The 7 fatal cases of scarlet fever showed a further decline from recent weekly numbers; they included 2 in Dundee. Of the 7 deaths from diphtheria, showing an increase upon the low numbers in the previous two weeks, 4 occurred in Glasgow and 2 in Edinburgh. All the 6 fatal cases of measles were returned in Glasgow; and the death from small-pox occurred in Aberdeen. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 109, 76, and 72 in the preceding three weeks, rose again last week to 80, and were 3 above the number returned in the corresponding week of last year. The causes of 85, or more than 17 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 26·7 and 27·6 per 1000 in the preceding two weeks, further rose to 29·4 in the week ending July 2nd. During the thirteen weeks ending on Saturday last the death-rate in the city averaged 28·7 per 1000, the mean rate during the same period being but 18·0 in London and 19·4 in Edinburgh. The 199 deaths in Dublin last week showed a further increase of 12 upon the numbers returned in the preceding two weeks; they included 30 which were referred to measles, 5 to diarrhœa, 3 to whooping-cough, 2 to "fever" (typhus, enteric, or simple), and not one either to small-pox, scarlet fever, or diphtheria. Thus the deaths resulting from these principal zymotic diseases, which had been 32 and 28 in the preceding two weeks, rose last week to 40, and exceeded the number in any previous week of this year; they were equal to an annual rate of 5·9 per 1000, the rates from the same diseases being 2·8 in London and 2·8 in Edinburgh. The fatal cases of measles, which had increased in the preceding eight weeks from 6 to 21, further rose last week to 30, and exceeded the number in any previous week of this year. The deaths from diarrhœa, whooping-cough, and "fever" also showed an increase upon the numbers in the previous week. The deaths of infants had declined, whereas those of elderly persons somewhat exceeded the number in the previous week. Six inquest cases and 5 deaths from violence were registered; and 61, or nearly a third, of the deaths occurred in public institutions. The causes of 24, or more than 12 per cent., of the deaths registered during the week were not certified.

TASMANIAN MORTALITY STATISTICS.

The Government statistician for the colony of Tasmania (Mr. Robert M. Johnston) has recently issued his return of the vital and meteorological statistics for the year 1886. Vital statistics relating to our Australian colonies, especially their mortality statistics, are full of interest for comparison with those of England and Wales. Their interest and value would, however, be far greater if we could be assured of the approximate accuracy of the civil registration of births, deaths, and marriages in our several colonies. Tasmania has the reputation of being one of the healthiest of our healthy Australasian colonies, and the statistics of the return just to hand fully corroborate this impression. This colony, with an area of rather more than 26,000 square miles, had last year an estimated population of only 135,501 persons. The recorded birth-rate of this population was equal to 34·2 per 1000, ranging from 36·8 in the chief urban districts (Hobart Town and Launceston) to 32·7 in the country districts. It may be noted that the birth-rate in the colony steadily increased from 30·2 in 1877 to 35·7 in 1884, since which it has somewhat declined again. It would be useful to know whether these differences may be attributed to varying accuracy of registration or to variations in the proportions of women at the child-bearing ages. The death-rate in the colony in 1886 was so low as 14·6 per 1000, showing a further decline from the rates in recent years. In the absence of official information on the point, it is fair to assume that the registration of deaths in recent years is at any rate fully as accurate as in past years. It is, therefore, very satisfactory to note that while the mean death-rate in the first five years on record (1856-62) was 17·2 per 1000, it did not exceed 15·7 in the last five years (1882-86). The return before us contains a singular defect (probably due to oversight) in its statistics bearing upon the mortality in 1886 in various parts of the colony. The death-rate in the year per 1000 of the mean population is given as 5·30 in Hobart Town, 3·33 in Launceston, and 5·95 in the whole of the country districts, while in the whole colony, as before stated, it is said to be 14·58. It would appear that by an oversight the rates given for the subdivisions of the colony are the proportions of deaths in each district to the *whole* population of the colony; these figures being, of course, valueless as a test of comparative mortality. It appears from the facts given in the table that the *true* death-rate per 1000 of the population of Hobart was 23·5, and that of Launceston 23·8; these are too high for rates in colonial towns, which should be free from the unhealthy areas which raise the death-rates of cities in the Old World. The death-rate in the Tasmanian country districts in 1886 would appear to have been as low as 9·4; this low rate may probably be partly due to defective registration in sparsely populated districts. It is unsatisfactory to find that "fever," principally enteric or typhoid, is more fatal in Tasmania than in England and Wales. The deaths in 1886 included 47 from this cause, of which 25 occurred in Launceston, 9 in Hobart Town, and only 13 in the rest of the colony. The mortality from the other principal zymotic diseases was decidedly below the English average. Infant mortality from all causes, measured by the proportion of deaths under one year to registered births, was 105 per 1000, comparing most favourably with the rate of infant mortality in England and Wales; it should, however, be noted that, while in the country districts the proportion was only 73 per 1000, it was more than twice as high (152 per 1000) in Hobart Town and Launceston, the chief urban districts. It is evident from these figures that the sanitary condition of the principal Tasmanian towns is not what it might be and ought to be.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon-General John O'Nial, C.B., has been granted retired pay (dated June 14th, 1887).

INDIA OFFICE.—The Queen has approved of the following promotions made by the Governments in India:—Surgeon-Major William Roe Hooper (dated March 31st, 1887), and Surgeon-Major John Richardson (dated April 29th, 1887), of the Bengal Medical Establishment, and Surgeon-Major A. Nickson Hojel (dated April 1st, 1887); Surgeon-Major Peter Stephenson Turnbull, M.D. (dated April 1st, 1887), and Surgeon-Major H. Cook, M.D. (dated April 2nd, 1887), of the Bombay Medical Establishment, to be Brigade Surgeons. This cancels the promotion of Surgeon-Major Hojel, from April 2nd, 1887, notified in our columns on May 21st, 1887.

ADMIRALTY.—The following appointments have been made:—Surgeon Penrose J. Barcroft, to the *Malabar* (dated July 2nd, 1887), and Surgeon William R. White, to the *Duke of Wellington*, additional (dated July 2nd, 1887).

ROYAL NAVAL ARTILLERY VOLUNTEERS (Bristol Brigade). Charles A. Wigan, M.D., M.R.C.S., to be Surgeon (dated July 4th, 1887).

Digitized by Google

ARTILLERY VOLUNTEERS.—1st Gloucestershire: J. Lidderdale, Gent., to be Acting Surgeon (dated July 2nd, 1887).—3rd Volunteer (Kent) Brigade, Cinque Ports Division, Royal Artillery: John Irvine Boswell, M.B., to be Acting Surgeon (dated July 2nd, 1887).—Richard Joseph Bryden, Gent., to be Acting Surgeon (dated July 2nd, 1887).

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the Duke of Cornwall's Light Infantry: Surgeon R. C. M. Pooley, M.D., is granted the honorary rank of Surgeon-Major (dated July 2nd, 1887); Thomas Baxter Carlyon, Gent., to be Acting Surgeon (dated July 2nd, 1887).—1st Dorsetshire: Acting Surgeon W. A. E. Hay, to be Surgeon (dated July 2nd, 1887).—1st Dumbartonshire: William Drysdale, Gent., to be Acting Surgeon (dated July 2nd, 1887).—1st Volunteer Battalion, the Essex Regiment: St. Clair Brockway Shadwell, Gent., to be Acting Surgeon (dated July 2nd, 1887).—4th Volunteer Battalion, the South Wales Borderers: Surgeon and Honorary Surgeon-Major Robert Smythe resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated July 2nd, 1887).—3rd Volunteer Battalion, the Duke of Wellington's (West Riding Regiment): Lieutenant J. F. Arlidge is appointed Acting Surgeon (dated July 2nd, 1887).

THE VOLUNTEER MEDICAL STAFF CORPS.—The London Division: Philip Henry Whiston, Gent., to be Surgeon (dated July 2nd, 1887).

Correspondence.

"Audi alteram partem."

THE POSITION OF MEDICINE IN THE STATE.

To the Editors of THE LANCET.

SIRS,—Now that the Jubilee week has come and gone, and the list of those deemed worthy of honour is open to our study, it seems a fit time for the medical profession to take stock of the estimate formed of it by the ruling coterie in the State. "Honour a physician with the honour due unto him" has come down to us from nearly 3000 years ago as embodying wisdom, and now in this marked year of our era we have an opportunity of testing how far these ancient opinions on the healing art are recognised under our so-called advanced civilisation. I take the list of honours as a fair index for guidance. The occasion was a special one, and furnished an opportunity for making up any leeway. The profession has not been passed by either as sufficiently weighted with awards or as unworthy of recognition, but duly considered and value assessed; and though the healing art is noble, second to none, and in the opinion of some self-sufficing, yet like other callings some of our members have accepted gifts from the "fountain of all honour," sinking their professional title in that applicable to the rank bestowed; and hence our profession, as to the nation's estimate of it, is fairly gauged by the distributions awarded its members. All professions, judging by acts, accept the honour as something above, and added to, that derived from themselves. What, then, does an analysis of the list reveal as bearing on our present subject?

Excluding promotions in the navy and army and those nursing sisters decorated with the Royal Red Cross, there are about 272 individuals deemed worthy of recognition, and among them we number twelve, six belonging to the civil segment and six to the services, a ratio of 4·4 per cent. Taking the navy and army as expressive of a calling the very opposite to the healing art, we find a ratio of 40 per cent., the medical departments among them reaching only to five. We have no place among the six peers and thirteen baronets; and among the knights commencing with Pryce Jones, Esq., and terminating with mayors of different towns, we have three out of thirty-three. Of the civil division of the Order of the Bath, its highest grade passing us by, we get two out of twelve K.C.B.'s, none out of thirty-one C.B.'s; and in its military division, giving us a similar omission in the highest grade, we have three out of forty K.C.B.'s, and three out of sixty C.B.'s. The Order of St. Michael and St. George, among sixteen colonials, give us one—an M.D. of Ottawa. Hence the healing art is deemed honourable by the State at a percentage of 4, one-tenth of the value of the fighting force; it is not worthy to take a place in the highest grade of any order in existence in our country; its level is with the trades; and former experience repeats the present. The medical profession has no high-paid and titled appointments as the church and law, and hence, acting on the principle advanced in the army, that the combatants are entitled to honours in a higher ratio than medical officers on account of the smallness of the pecuniary remuneration, we should have an excess as compared to others, and this makes the invidiousness of our present position more pronounced. Thus this Jubilee year finds us lowly rated and lowly graded in the bestowal of distinctions; it finds no small number of our military members smarting (rightly or wrongly) under a sense of degradation and unfairness; it finds several in our lower ranks who in the struggle for existence are working for a pittance barely, if at all, above the artisan class. Surely there is food here for reflection and occasion for reasonable discontent, irritation, and a desire at least (to use your own words) for "redress of what is felt to be a grievance," if nothing more.

Does the cause of offence lie in our calling, in ourselves, or in the power that honours? The first may be dismissed, though it must be said that it places the sufferer only under an obligation; its influence is personal rather than general; it is not obtrusive; it makes no appeal to the emotions of the mass as an army does in a victory gained, or as politics in a great liberating measure passed; in its public work it is preventive and silent in working, unseen by the many, not demonstrative; and hence its value and influence are easily overlooked in this busy world and thrust aside. Again, its members are not recruited from the upper strata, from the moneyed or influential ranks—rather from the medium or lower middle class as a rule. They come under the category of self-made men; they have little time or desire or means for social matters; they do not come much under the cognisance of those capable of influencing the inner circle surrounding the throne except as units. Nor are they potent politically. Their main power resides in the position their special education gives them in the world of intelligence, and their influence is probably best seen in those who carry their medical education into other spheres of work than in those who practise the healing art. Again, in the distribution of honours, it would appear, judging by the results, not to be based solely on professional work, the selection, the outcome of a responsible body having the necessary knowledge. In the civil section several have been distinguished by Royalty after services personally rendered; and in the military section seniority has generally determined the result, and the awarder has been the military, not the professional head. Hence it would seem that our calling is not one to prominently thrust itself under the nation's recognition; its members, as a rule, lack the social or political influence to impress the fountain from which honours flow, and the system of awarding leaves much to be desired. These points, however, furnish no excuse for the poor distinction that the medical profession has hitherto enjoyed. Surely the State should have no favouritism in professions or callings, all (if honourable) should stand on the same basis, and awards in ratio to numbers should be mainly based on selection made by the respective heads acting in council.

I presume that the profession regard the present condition as one far from congratulatory. We want to extend our influence socially and politically; we want to raise the standard of our profession, increasing its value and power in the State. Most of us tend to undermine our power by the ease with which we gratuitously give our professional services. We want our ranks recruited more, if possible, from the upper middle stratum, and especially to guard against the numerical swamping of the profession by the entrance of more than can be properly provided for. This is unquestionably a great rock ahead, increasing competition and the struggle for existence not probably affecting those in the first rank or those of middle age, but vitally touching those about, or in the future, to enter, and increasing the numbers earning a miserable pittance, degrading in tendency, besides reducing the influence of the profession as a whole, and allowing the State to fill its posts with men at a lower rate. It is certainly the best for all that this severe competition for work and its pay should be prevented, that entries should not be double the vacancies as at present; and to this end it would seem well that the Colleges should use their authority, and by raising the required standard increase the difficulties, so diminishing the number passed

Digitized by Google

in, while augmenting the value of the passed professionally and socially. Both of these points we want, if the profession is to have due weight in the State, and such are the thoughts which have passed through the brain of

July, 1887. ONE OF ITS MEMBERS.

"ACUTE EPIGASTRIC PAIN IN PUERPERAL ALBUMINURIA."

To the Editors of THE LANCET.

SIRS,—I beg to enclose extracts from a private letter recently received from Dr. Goss, giving additional evidence of the value of the symptom I alluded to in a recent issue:—

"Roxbury, Boston, Mass., U.S.A., April 28th, 1887.

"MY DEAR SIR,—In the report of a case of 'Acute Epigastric Pain in Puerperal Eclampsia,' published in THE LANCET of the 2nd inst., you do me the honour to refer to a case published by me in the *Boston Medical and Surgical Journal* in 1884. Towards the close of your article you say: 'The above cases, five only in number, are all I have been able to meet with.' It may interest you to know that since the publication of my case others of a similar nature have been observed in this vicinity. In the *Boston Medical and Surgical Journal*, vol. cxi., Dec. 18th, 1884, p. 580, Dr. C. F. Withington gives an account of the malady in question, and in vol. cxiii. of the same publication, Sept. 24th, 1885, p. 299, the late Dr. F. H. Lombard published a case reported to the Boston Obstetrical Society. ..... In spite of all reasonable care, the presence of renal trouble will sometimes escape our notice till a catastrophe occurs. Dr. Lombard reported that the urine of his patient had been examined monthly up to within a fortnight of her decease, without discovering any abnormality, and there was nothing in the condition of my patient to lead me to suppose her situation to be critical. The renal affection must be at times very rapid in its development, and the microscopical examination of the urine in both Dr. Lombard's case and my own confirms this statement. The urine resembles that often found in the acute nephritis of scarlet fever.

"Trusting, &c. ..... Yours, very truly,

"FRANCIS W. GOSS.

"John Phillips, Esq., B.A., M.B., M.R.C.P."

I may also say that I have received letters from two other practitioners detailing single cases in which this very important and too-little noticed symptom was well marked.

I am Sirs, yours truly,

Harley-street, W., July 6th, 1887. JOHN PHILLIPS.

"A DOCTOR'S INCOME."

To the Editors of THE LANCET.

SIRS,—My good friend Dr. Paget Thurstan, who is better qualified than many hospital physicians, has succeeded in raising a lively discussion on this—to us doctors—most interesting question. Permit me, as a man who knows the world better I suspect than some of my brethren, to make a few remarks on the subject. The general public care little what a doctor does or is, provided they know his name well; they draw no distinction between consultants so-called and general practitioners, and, most naturally, we should do the same in their place—get the best advice at the lowest fees. Again, hospitals, clubs, and dispensaries offer good treatment at low fees the public will accept all they can get, and as much more. Our medical brethren in general quite forget that clubs do not exist to provide medical treatment; their primary object is to supply their members with so much per week in sickness, and certain benefits at death. The medical attendance is thrown in in a secondary kind of way. Now, as long as twenty practitioners offer themselves for a club surgeoncy, as long as club doctors holding the highest qualifications, are ready to go *twelve miles* to see club patients, speak of facts—the public would be lunatics to offer more than the 2*s.*, 4*s.*, or 5*s.* generally paid for medical attendance. So no wonder at young men taking such work as they can get at present practice and are glad of anything to do, but I do wonder at eminent men offering themselves. A [illegible] surgeon to a great provincial [illegible] to his death many clubs. I do [illegible] he held forty clubs. Again, [illegible] neighbourhood several rich people, [illegible] the local doctors have gone as in-patients to London hospitals of late years. As long as great hospitals compete for inmates and gladly receive any and all comers, the public naturally think (if they trouble themselves at all in the matter) that the staff are remunerated somehow and sufficiently. One remedy would be for our great consultants to resign their hospital appointments earlier in life; a second, a more systematic weeding out of hospital patients. At this moment there are several poor sufferers in my neighbourhood whom I would gladly send away for severe operations, but they cannot face the cost of the journey; at the same time rich shopkeepers, large farmers, and prosperous business men, who can get up to town, are eagerly received again and again. Moreover, I must demur to the singular statement that consultants are a different class to general practitioners. The distinction between barristers and solicitors will not continue; public opinion is against it. Consultants are not always better qualified or more competent than general practitioners. With the exception of part of the staff of certain London hospitals, there are hundreds of consultants (so-called) whose education, diplomas, and standing are precisely the same as those of good general practititoners. One of our local club doctors is a London University scholar. The corporations can do nothing; Parliament cannot and will not interfere; and as for the Medical Council, what right has it to interfere? Combination will effect nothing. Our leading men must protect themselves from downward competition, and our younger men must have more self-respect.

I am, Sirs, yours truly,

June, 1887. AN OLD OXONIAN.

A THERAPEUTICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—I sincerely hope that the scheme of a Therapeutical Society, as mooted by Dr. A G. Bateman, will be carried out to a successful issue. To general practitioners, intimately concerned as they are with the actual and immediate treatment of disease, such a society would be of inestimable value. As a matter of fact, a great number of practitioners scan the medical papers with avidity that they may pick up any therapeutical crumbs which perchance might fall from those in high places, and truly they are, as a rule, but crumbs, the feast itself generally consisting of pathology or etiology. In other words, the science of therapeutics has not received the same amount of attention as other branches of medicine have, and is still, as your correspondent states, in a "chaotic condition," from which, however, a Therapeutical Society would go far in helping it to emerge. Trusting that the idea may be taken up with the enthusiasm it deserves, I remain, Sirs, yours truly,

Hastings, July 7th, 1887. J. STENSON HOOKER.

VANS AND INFECTION.

(*From a Correspondent.*)

AN outbreak of measles has been traced at Grantham to some travelling showmen and hawkers who attended the fair recently held in the town. The case affords a good illustration of the danger to the public health which results from the extremely unsatisfactory character of our sanitary system so far as it affects our nomadic population. This question was discussed at considerable length during the sittings of the Housing of the Working Classes Commission two years ago. It was then shown that the van population—under which generic term was included that numerous class who inhabit movable dwellings, whether vans or tents—were subject to no sanitary regulations whatever. A magisterial decision, that a van was not a house, had been upheld by the High Court, with the result that none of the enactments which regulated the inhabitants of houses affected this vagabond section of the community. In some parts of the country, it is true, where van towns had sprung into existence, some attempts had been made to cope with the difficulty. At Woodford, for instance, where the squatters ejected from Epping Forest made a settlement, the local board succeeded in compelling them to have a supply of water. But it is doubtful whether this was a legal proceeding, and the settlement, of course, still re-

Digitized by Google

mained independent of the bye-laws of the board. And this was the state of things all over the country. As to the condition of these people, it was shown to be admirably adapted to breed pestilence. Cases of typhoid fever and small-pox were frequently occurring among them, vaccination, owing to their migratory habits, being unknown, while they furnished instances of overcrowding of the worst type. An attempt was made, it will be remembered, to bring vans within the Canal Boats Act, but the House of Commons committee reported against the proposal, and Mr. George Smith of Coalville, has since been indefatigable in urging the necessity for a "Movable Dwellings Bill." It is, however, in the meantime, of considerable importance that it should be remembered that sundry of the recommendations of the Royal Commission with regard to vans and tents were carried into effect by the Housing of the Working Classes Act, 1885. That statute, for instance, extended the Public Health Act, 1875, and the Sanitary Act, 1866, so as to include any structures used for human habitation. It declared, in so many words, that if any tent, van, or shed were so overcrowded as to be injurious to the health of the inmates, it should be deemed to be a nuisance. Sanitary authorities and nuisance authorities were further empowered to make bye-laws for promoting cleanliness in this class of dwellings, and for ensuring their being kept in a habitable condition and preventing the spread of infectious disease by those inhabiting them. Any person duly authorised by a sanitary authority or by a justice of the peace was enabled, if he had reasonable cause to suppose either that there was a contravention of the provisions of the Act or bye-laws or that any person was suffering from any infectious disorder, to enter any such structure between the hours of six in the morning and nine in the evening, and any person obstructing him in the performance of this duty was liable on summary conviction to a fine of forty shillings. From all this it will be seen that pending further legislation there is plenty of authority under the Act of 1885 for taking all necessary precautions to prevent infectious diseases being introduced into towns by this means. It is true that the commissioners expressly limited their recommendations to those cases in which van towns were located near populous places, and did not propose to interfere with the nomadic population. But there is no such limitation in the words of the Acts which apply equally to travelling vagabonds and settlers. The Grantham authorities intend, it is said, to inspect caravans in future before they are permitted to enter the town; and, as we have shown, they possess full authority to carry out such a precaution. Bye-laws which have been framed under the Act have been carried out to much good purpose in Battersea and Wandsworth and in a few other districts, but in comparison with their obvious utility these provisions of the statute have been so little used that it may be doubted whether their existence or effect are generally known. It is certainly of the first importance, in view of its influence upon the public health, that no pains should be spared to render the itinerant masses amenable to sanitary regulations, and it therefore seems to be very desirable to call attention to the existing statutory powers in that behalf.

MANCHESTER.

(From our own Correspondent.)

ROYAL INFIRMARY.

A DEATH from hydrophobia has recently occurred in the wards of the infirmary; the patient had been bitten by a dog a month previously in one of the outlying districts of the town. It is not long since another death took place in a patient at the opposite side of the city. It is satisfactory to note that the authorities are now enforcing the regulations for the proper control of all dogs throughout the city. Jubilee Day passed without any very serious accident happening; a few minor casualties were brought in, together with one or two persons suffering from the effects of the heat or alcohol, or the two combined. A catastrophe caused by the sudden falling of some business premises furnished some half-dozen patients recently, when two persons were killed. This unfortunate affair has had the good effect of directing attention to the need for increased supervision by the authorities, not only of new buildings, but over alterations of existing premises. Another case under treatment in the infirmary has been of interest, not so much from the nature of the accident as from the manner in which it was inflicted. A man at one of the theatres became so carried away by the acting that he jumped from the gallery on to the stage to render assistance to the heroine against the evil designs of the villain of the piece, in attempting which he broke his leg and had to be taken to the infirmary.

PRESENTATION TO DR. WATERS.

At the annual meeting of the Lancashire and Cheshire branch of the British Medical Association, held at Stockport, a presentation was made to Dr. Waters of Chester, consisting of a service of silver plate, in token of recognition of his services in connexion with the work entailed by the last piece of medical legislation. Subsequently the members proceeded to the Jubilee Exhibition at Old Trafford, where they dined and spent an exceedingly pleasant evening together. While speaking of the exhibition, it may be remarked that, owing to the occurrence of various accidents &c., amongst the huge numbers of visitors to this most successful of exhibitions, the committee have engaged the services of a qualified surgeon to be always on the spot, and many of the employés and attendants have been undergoing a course of "ambulance lectures."

MANCHESTER DEATH-RATE.

THE LANCET of June 25th contains a short article on the high mortality prevalent in Manchester, both during the last year and for some years past. The health authorities here are certainly not ignorant or unmindful of this unsatisfactory position of our city among the large towns of the country, but there are one or two facts which ought to be borne in mind when comparing Manchester with other places. In the first place, the density of the population is greater here than in any other town except Liverpool; and secondly, and perhaps of more importance still, Manchester, as represented by the municipal boundary, is, as far as the resident population is concerned, almost a city of cottages and poor property, and contains in excess that section of the community amongst whom the highest death-rates always prevail. The large warehouses and business premises contain no residents.

THE MAYOR.

The comparatively sudden death of the Mayor (Mr. Alderman Curtis) just before the Jubilee rejoicings was deplored by all. It is certain that had he lived he would have received the honour of knighthood, as has the Mayor of the neighbouring borough of Salford. For many years Mr. Curtis took much interest in the management of the affairs of the Royal Infirmary, and held the position of chairman of the Convalescent Hospital at Cheadle, where he will be much missed.

OWENS COLLEGE.

June 17th was "Associates' Day" at Owens College, when a large number of visitors assembled in the chemical theatre to hear the annual report, &c. The Council have elected twenty-one graduates to the associateship —i.e., eight in science, one in medicine, and five in arts of the Victoria University, three in science and one in medicine of the London University, two in arts of the Cambridge University, and one in arts of the Oxford University. Many old medical students in the College during the years 1873 to 1877 will learn with regret of the early death of Mr. J. B. Perrin, who during that time was demonstrator of anatomy. He was himself a Manchester student, and afterwards held posts in London at King's College and in the College of Surgeons, prior to his appointment here, since resigning which he has had a large practice at Leigh, near Wigan.

June 28th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE WATER SUPPLY OF NEWCASTLE.

IN view of the present dry season the water supply of the city of Newcastle has lately come to the front, and a meeting of the special committee of the Corporation has recently been held on the subject. It was mentioned that the new reservoir at West Hallington might be soon completed, which would give a storage of 700,000,000 gallons. It was

Digitized by Google

shown at the meeting that the water supply to Newcastle and Gateshead is about 15,000,000 gallons daily, of which 11,000,000 gallons are drawn from the water stored in the reservoirs and 4,000,000 gallons from the Tyne. The company, seeing that owing to the dry weather the quantity of water in store was rapidly decreasing, got the pumping engines at Wylam ready for use a month since, and a fortnight ago commenced pumping from the Tyne, and this water is delivered by a separate system of pipes to manufactories, and does not mix with the water supplied for domestic use. At the present time about 4,000,000 gallons per day are being pumped from the river, the pumping power being equal to 6,000,000 gallons a day. The quantity of water in store in the reservoirs on the 29th ult. was more than 1,000,000,000 gallons, which is equal to a supply of about 120 days, so that the people of this district need not fear a water famine.

THE DURHAM COUNTY ASYLUM.

A long report has been presented from the visiting justices of the Sedgefield Asylum respecting the crowded condition of that establishment. The visitors had anticipated that the institution might answer its purposes for some years longer without further additions under ordinary circumstances, but the action of the Sunderland guardians in demanding that all their chronic insane should be admitted into the asylum had upset their calculations, and, in consequence, they had been compelled to enter into arrangements for the reception by another asylum of 150 patients from Sedgefield for two years. The visitors regretted this, as the duty of an asylum appeared to them to be the *cure and treatment* of insanity rather than the custody of the insane. In view of this state of matters the visitors made various suggestions, one of which was the erection of a new asylum in the northern part of the county of Durham for 500 patients, at a cost of £75,000.

THE BLIND POOR OF NEWCASTLE AND GATESHEAD.

On Saturday last the Society for the Home Teaching of the Blind were enabled by the kindness of friends to convey the blind poor of Newcastle and Gateshead, to the number of about 170, in brakes, for a day's outing in the Armstrong Park, where they were supplied with refreshments and entertained with music; not only this, but the men were measured in the Park for trousers and the women for dresses, as a Jubilee gift from the kind friends of the Society. The blind guests were conveyed home to their several houses without a single accident to mar the day's enjoyment.

THE LEEDS WORKPEOPLE'S JUBILEE GIFT.

The workpeople of Leeds have contributed £500 as a Jubilee offering, which is to take the form of an ambulance carriage for the Leeds Hospital. It is to be constructed to carry four stretchers, two with wheels and two slung from the roof. The interior is convertible by loose cushions and backs into suitable beds. It is to be light enough for one horse to draw it short distances; a pole and bar for a pair of horses is also supplied complete, with easy springs and indiarubber axles, sun blinds, lamps, and all the latest improvements.

Newcastle-on-Tyne, July 4th.

DUBLIN.

(From our own Correspondent.)

UNIVERSITY OF DUBLIN.

At a meeting of the University last week, the degree of Doctor of [illegible] (*honoris causâ*) was conferred upon William Tennant Gairdner, Sir James Paget, Sir Thomas Spencer Wells, Sir John Simon, and Edward Waters.

JUBILEE HONOURS.

It is stated that the list of Irish Jubilee honours will not be announced publicly for three or four weeks; and in the interval perhaps the Government may see the folly and injustice of refusing to medical men in this country what has been granted to their brethren in the sister country. Rumour has it that at least two [illegible] will receive distinctions in honour of the [illegible] trust that the statement may be [illegible]

JUBILEE WARDS: NATIONAL CHILDREN'S HOSPITAL.

The two new Jubilee wards, styled respectively "Victoria" and "Albert Victor," which were inaugurated last week by H.R.H. Prince Albert Victor, are now open for the reception of patients. On Monday last the twenty-four beds were for the first time utilised. Although the hospital is situated in the city, the situation is very open, and, so far as ventilation and light are concerned, nothing could be better than it possesses in these particulars. A sum of £2000 is required, of which about £1000 has already been subscribed. I am confident that the energy and enthusiasm of Mr. L. Hepenstal Ormsby, the surgeon to the hospital, will succeed in enlisting the sympathies of the charitable, and obtain for a valuable institution the amount still required.

MERCER'S HOSPITAL.

On Monday last the Vice-Chancellor had before him the case of Mr. Edward Stamer O'Grady, an eminent Dublin surgeon, against the governors of Mercer's Hospital and Dr. C. F. Knight, in which he sought an order restraining the defendants, until the hearing of the action, from removing the plaintiff from his position as surgeon and governor of the hospital. Defendants asked for an adjournment, which was agreed to, an undertaking being given by them not to take the action which was sought to be restrained, pending the hearing of the cause. Certain of the governors who dissent from the board were also represented by counsel. There is a probability that the case may not be heard during the present sittings.

EPIDEMIC OF MEASLES IN DUBLIN.

For the past three months measles has been very prevalent in Dublin, and the number of deaths from this affection unusually numerous. For example, during the last five weeks the deaths from measles have amounted to eighty-four, as contrasted with four deaths during the first twelve weeks of the present year.

A child seven years of age died in the Waterford Workhouse last week from sunstroke.

Dublin, July 5th.

MEDICAL TRIAL.

PALMER *v.* MALLET.

IN the Chancery Division of the High Court of Justice, this case came before Mr. Justice Chitty. It raised a question of importance to the medical profession. It appeared that the defendant, a medical practitioner, had in 1885 entered into an agreement to act as assistant to Messrs. Palmer and Hall, two medical practitioners practising together in partnership at Newtown, Montgomeryshire. Messrs. Palmer and Hall having dissolved partnership and continued practising in Newtown separately, the defendant entered into the service of Hall, and the plaintiff, Palmer, complained that this was a breach on the defendant's part of the agreement, which was to the effect that the defendant should not directly or indirectly, or either alone or in partnership with or as assistant of any other person or persons, or otherwise, set up or carry on the profession of a surgeon, &c., at or within ten miles of Newtown, without the consent in writing of Hall and Palmer, their executors, administrators, or assigns. The defendant submitted, *inter alia*, that the agreement was a contract with Palmer and Hall jointly, and not a several contract with the plaintiff Palmer, and that the partnership being at an end he was at liberty to disregard the agreement. Mr. Romer, Q.C., and Mr. Alan Stewart appeared for the plaintiff; and Mr. Aston, Q.C., and Mr. Yate Lee for the defendant. Mr. Justice Chitty said that, in his opinion, the plaintiff could sue on the agreement without joining Hall, and granted an interim injunction restraining the defendant from acting in the way complained of. On the application of the defendant, the operation of the injunction, with the consent of the plaintiff, was suspended for a month.

BLIND EDUCATION.—Mr. H. Warmington, a blind young gentleman, has passed the "previous" examination in Cambridge University, obtaining a first class in part 1 and in part 2, and a second in the "additional subjects." Mr. Warmington was educated in the Worcester Blind College.

Digitized by Google

THE COLLEGE ELECTION.

THE voting at the above election, which took place in the Library of the Royal College of Surgeons on Thursday afternoon, the 7th inst., resulted as follows:—

Mr. Jonathan Hutchinson ...	120,	including	0	plumpers
Mr. Alfred Willett...	106	,,	27	,,
Sir T. Spencer Wells, Bart. ...	77	,,	2	,,
Mr. R. Brudenell Carter ...	67	,,	14	,,
Mr. John Couper	59	,,	6	,,

Mr. Jonathan Hutchinson and Sir T. Spencer Wells, Bart., were therefore duly re-elected, and Mr. Alfred Willett was elected to the vacancy caused by the retirement of Mr. John Wood.

There appeared to be less interest in the election than is usual; only 199 Fellows recorded their votes. One paper only was declared invalid from informality.

There was the usual exhibition of pathological specimens and preparations illustrative of human and comparative anatomy which have been added to the museum during the past year. Most of these are of special interest.

Medical News.

UNIVERSITY OF OXFORD.—At a congregation held on the 23rd ult. the following degrees were conferred:—

DOCTOR IN MEDICINE.—George Alfred Buckmaster, Magdalen.

BACHELOR IN MEDICINE.—William Wallis Ord, University; John Arkle Waring, New; Frank Sorell Arnold, Percy John Frederick Lush, and Lovell Drage, Christchurch; Ernest Le Cronier Lancaster, St. John's; William Williams and Charles Hubert Hands, non-collegiate; Frederick William Andrewes (Fellow), Pembroke; George Lindsay Turnbull, Magdalen.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following having passed their final examinations for the Letters Testimonial of the College under the old scheme regulations have been admitted Licentiates:—

James Burke, James Cahill, William J. Corrigan, Isaac Duncan, William V. Furlong, Nicholas John Gossan, William J. Mullany, Vincent Nash, Henry F. C. Pilcher, Matthew J. Dingley, Henry M. Rainsford, James M. Tidmarsh, and Benjamin P. Young.

Nineteen entered, one was absent, and five were rejected.

The undernamed have been admitted Fellows:—

F. A. B. Daly, A.M.D. | D. D. Redmond.

UNIVERSITY OF DUBLIN.—The following degrees were conferred last week by the Chancellor of the University:—

BACHELOR IN SURGERY.—Walter James Buchanan, Joseph Chambers, John Galwey Cooke, Parke Shaw Dobson, George Faris, Harry Fayle, John Hugh Roberts Glenn, St. George Gray, Christopher James Healy, Robert William Henry Jackson, Rev. Henry Simpson Lunn, Patrick Colley Pounder, Samuel William Robinson, Henry George Smeeth, John Henry Du Bedat Whaite, Charles William Henry Whitestone.

BACHELOR IN MEDICINE.—Henry Kingsmill Abbott, Samuel William Allworthy, William Sydney Bagot, Joseph Chambers, James Clarke, Thomas Willoughby Cole, John Galwey Cooke, John Cuffey, Edwin Lindsay Dunn, Harry Fayle, Edward Barrington Ffennell, Dionysius Lionel Fitzgerald, William Samuel Tomkins Foley, St. George Gray, Charles Grey-Edwards, Christopher James Healy, Robert Warren Herrick, Wensley Moore Jennings, John Freeman Knott, Thomas William Gordon Kelly, George Lane Mullins, Samuel William Robinson, William James Weir, Charles William Henry Whitestone, Humphry Worthington.

MASTER IN OBSTETRICS.—Hugh Woods.

DOCTOR IN MEDICINE.—Robert Samuels Archer, Arthur Wyndowe Willert Baker, Henry St. John Brooks (*stip. cond.*), William Morton Harman, Rev. Henry Simpson Lunn, Henry Brougham Pope, Richard Blayney Wrightson.

SOCIETY OF APOTHECARIES.—The following gentlemen having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates entitling them to practise as Licentiates of the Society on June 30th:—

Anderson, Ernest Chester, Chaplaincy, Bodmin.
Creasy, Arthur Zell Claydon, Hayesden, Wallington Surrey.
Doidge, Maurice John, Lifton, Devon.
Miles, Charles Henry, Stantonbury, Bucks.

ON the 29th ult. a concert was given at Exeter in aid of the funds of the Devon and Exeter Hospital.

THE first annual celebration of the Leeds Hospital gala was held on the 2nd inst., and proved highly successful.

THE annual general meeting of the trustees of the Salop Infirmary was held on the 18th ult. The business transacted was mainly of a formal character.

NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.—The tenth block of houses of this hospital will be inaugurated by H.R.H. the Princess Beatrice on July 21st next.

MR. WILLIAM P. BAIN, late medical officer for the East District of the Poplar Union, has after forty years' service been granted a superannuation allowance of £121 per annum.

ON the 3rd inst. the annual demonstration of the friendly societies in Sunderland took place, the collection on behalf of the medical charities of the town resulting in the receipt of a highly satisfactory amount for distribution.

THE existence at Leicester of several dogs suffering from rabies has been brought to the notice of the local police authorities, many of the inhabitants having been attacked by the animals.

VACCINATION GRANT.—Mr. J. B. Emmerson, public vaccinator for the Stotfold district of the Biggleswade Union, has been awarded the Government grant for efficient vaccination (first time).

THE AFTER-CARE ASSOCIATION for poor and friendless female convalescents on leaving asylums for the insane will hold its annual meeting on Thursday next, at 3 P.M., at 83, Lancaster-gate, Hyde Park, Dr. Hack Tuke in the chair.

ADELAIDE HOSPITAL, DUBLIN.—The following prizes have been awarded:—Hudson Scholarship: Gold medal and £30, Thomas E. Dunne. Hudson Prize: Silver medal and £10, Christopher Healy. Medical Prize: C. W. Healy. Surgical Prize: R. J. W. Mawhinny.

ON the 28th ult. Mr. James Shaw, of Ardwick, near Manchester, was found dead in his house, which he occupied alone. The cause of death, which had occurred about ten days before the discovery of the body was made, was due to valvular disease of the heart.

UNIVERSITY COLLEGE, LONDON.—On Saturday, July 2nd, the Council of the College made the following appointments:—Dr. W. J. Williams, F.R.C.P., Professor of Midwifery; Dr. H. Charlton Bastian, F.R.S., Professor of Medicine; Dr. W. J. Mickle, F.R.C.P., Lecturer on Mental Diseases; and Dr. W. R. Gowers, F.R.S., a Professor of Clinical Medicine.

CASES OF POISONING.—Nine children living at Pollokshaws, near Glasgow, were on Tuesday last seized with illness of an acute character, in consequence, it is supposed, of having picked up and eaten portions of a white substance, possibly arseniate of soda, which they mistook for alum. Two of the children have since died, the others are recovering.

THE Howard Association have issued an appeal for assistance to enable them to publish widely in the course of next year three works, which their secretary, Mr. Tallack, has prepared, bearing on prison discipline, and the treatment and prevention of crime. The works embody important facts, figures, and observations collected by the society during the past twenty years.

SANITARY INSTITUTE OF GREAT BRITAIN.—At the anniversary meeting to be held on Thursday, July 14th, at 3 P.M., Sir Douglas Galton, F.R.S., will present the medals and certificates awarded to the exhibitors at the exhibition held at York, after which ceremony an address will be delivered by Dr. G. V. Poore, entitled "The Shortcomings of some Modern Methods of Sanitation."

BEQUESTS.—The late Captain Douglas, formerly of the Scots Fusilier Guards, has bequeathed £500 to the Westminster Hospital, £200 to King's College Hospital, £200 to the Home for Sick Children, Great Ormond-street, and £300 to St. Mark's Hospital, City-road.—Mr. Richard Kemmis has left £100, and the Countess Dowager of Pembroke £100, to Sir P. Dun's Hospital, Dublin.

DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY.—At a meeting of the committee of management of this hospital, held on the 2nd inst., it was reported that during the half-year ending 30th ult. 1027 in-patients had been admitted, 750 discharged as improved, 28 as no better, and 7 at their own request; 234 remained on the books. The number of out-patients treated during the same period was 72, and of these 34 were discharged as improved. The financial report was satisfactory.

Digitized by Google

DR. NAISMITH, whose services to the Ayrshire Yeomanry Cavalry as instructor in ambulance drill for mounted troops were specially noticed by the inspecting officer, Colonel Lord Ralph Kerr, at the recent review of the regiment, has improvised a stretcher made with four swords and a piece of canvas, the swords, two on each side, being fastened at the centre by two simple clamps, carried in the pouch belt.

CITY PROVIDENT DISPENSARY AND SURGICAL APPLIANCE ASSOCIATION.—The tenth anniversary dinner of the supporters of this charity was held on the 29th ult., the Earl of Dartmouth presiding. During the ten years of its existence there have been 27,257 attendances at the dispensary and 2056 visits paid at homes. In the surgical appliance branch upwards of 7400 instruments have been supplied. During the evening the secretary announced subscriptions amounting to about £280.

EAST SUFFOLK AND IPSWICH HOSPITAL.—The anniversary court of the governors of this institution was held on the 29th ult., when it was reported that 712 in-patients had been admitted, against 707 in the preceding year, and 4423 out-patients, against 3998. The ordinary revenue account showed an excess of expenditure of £370 over the income, which, added to an adverse balance in the previous year of £209, left a deficiency of £579. The report was adopted, and the court was adjourned for three weeks in order to allow the board of management to report as to the propriety of electing an assistant house-surgeon to the institution.

MEDICAL NOTES IN PARLIAMENT.

Supply of Drugs to Prisons.

IN the House of Commons on the 30th ult., in reply to Mr. Picton, Mr. Matthews stated that in April, 1886, tenders were invited for the supply of drugs and sundries to Her Majesty's prisons; that the accepted tender was at the rate of 12½ per cent. discount off the list of prices supplied by the department; that one of the rejected tenders was at the rate of 20 per cent. discount; and that the firm sending in the lower tender had been in the habit of supplying several great hospitals, and furnished testimonials of competency and trustworthiness from upwards of thirty well-known medical men in various parts of Great Britain and Ireland; and that the reason assigned for the payment of a price 7½ per cent. higher than that for which the drugs could have been obtained was that it was held, and very reasonably, by the medical inspector of the department that contractors who have been tried and tested as supplying pure drugs should be preferred unless some considerable advantage was to be gained by not doing so. The difference of price referred to in the question would not for the whole of the prisons amount to more than £95. He saw no reason to interfere with the practice of the department, which was, he believed, similar to that followed in other public departments and large hospitals.

The Vaccination Acts.

In reply to Mr. C. Hanning, Mr. Matthews stated that he was not prepared to advise any special mode of treatment for persons imprisoned under the vaccination laws.

The Medical Staff in India.

On the 1st inst., Sir W. Forster asked the Under-Secretary of State for India whether it was the case that an executive officer of the medical staff in India, who officiated for less than one month as deputy surgeon-general in the absence of the deputy surgeon-general on sick leave or furlough, received no allowances for the period, although he performed the duties in addition to his other duties; whether in such an instance the "half-staff" of the appointment reverted to the State; whether the acting officer would be held pecuniarily liable in the event of loss of stores or other mistakes; whether officers officiating on the military (combatant) staff in a similar way would draw the "half-staff" for broken periods; and why the difference was made in the case of the medical officers.—Sir J. Gorst replied that the Secretary of State had not yet obtained the official information from India which was necessary to enable him to reply to this question. It had been asked for.

Dispensary Doctors in Ireland.

On the 4th inst., in reply to Mr. T. Harrington, Mr. A. J. Balfour stated that it was usual to select as constabulary medical attendant the dispensary officer of the district when he was found to be the most eligible, but not otherwise. The rule giving a doctor a certain priority of claim to the medical charge of the police situate within his dispensary district was cancelled in 1883.

Army Medical Officers.

The following is the text of the question put a few days ago by Dr. Farquharson, and of the answer by Mr. Stanhope:—Whether the Secretary of State for War is aware that considerable dissatisfaction exists in the Army Medical Department as the result of recent examinations for promotion from the rank of Surgeon-Major to that of Brigade Surgeon; whether it is the case that the unsuccessful competitors heard for the first time after their failure that they were not to be allowed a second chance, but must be passed over when their time for promotion came; whether this rule applied equally to combatant officers; and whether, in consideration of the fact that several medical officers of long service and proved capacity presented themselves for examination on the recommendation of the Director-General, and under unfavourable conditions, in the belief that a second opportunity would be afforded them of satisfying the requirements of the Board, he will consider whether he cannot relax the rule in their favour.—Mr. Stanhope, in reply, said, "I am not aware that there is considerable dissatisfaction, but I have understood that certain Surgeons-Major have felt aggrieved at not being allowed a second chance, although it does not appear that they had any right to expect it. Promotion to the rank of Brigade Surgeon is strictly by selection, and the fact of passing the examination does no more than remove the presumption of disability for promotion. The selection would be made from those Surgeons-Major of marked ability who had passed the test; and it is to be inferred that if any officer required more than an examination before he could prove his ability, it is unlikely that he would be selected as of conspicuous ability for the higher rank. The case of combatant officers is altogether dissimilar."

On the 4th inst., Dr. Farquharson asked the Secretary for War whether it was true that the commissions of army surgeons were dated after leaving Netley, whereas surgeons in the Indian army and also in the navy had their commissions dated—the Indian surgeons from the day of joining at Netley, and the naval surgeons from the day of joining at Haslar; whether this gave both Indian and naval surgeons an advantage of four months' seniority over the army surgeons who passed the same competitive examination at Burlington House with them; and whether he would undertake to do away with this distinction between the medical officers commissioned for duty in the three public services of the Army, Navy, and India.—Mr. Brodrick said that the facts were as stated. Whether the army surgeons experience any practical inconvenience from the antedate given to Indian and naval surgeons might be doubted. He thought that the best way to remove the anomaly would be for the Admiralty and the India Office to follow in future appointments the practice of the War Office.

On the 5th inst., Dr. Farquharson asked the Secretary of State for War whether he would take means to ascertain the ground of the present feeling of discontent among the medical officers of the army with their anomalous position, which, they allege, affords them neither relative nor substantive rank in the army; and whether he would enable them collectively to state their grievances to him and to suggest the desired remedies.—Mr. E. Stanhope said that he had already received a deputation from the civil branch of the medical profession on this subject, and that it would be a breach of military discipline for military medical officers to unite in any collective expression of complaint.

Water-supply at Albany Barracks, Parkhurst.

On the 5th inst., in answer to Dr. Cameron, Mr. E. Stanhope stated that the ordinary water-supply of Albany Barracks, Parkhurst, is derived from the surface water of an adjoining forest, but after being collected the water is passed through ample filtration beds. This water has been repeatedly analysed, and after filtration pronounced good and wholesome, but recently, from the long drought and other causes, the supply has become insufficient and of inferior quality. In April there were three cases of typhoid fever, and in the absence of any other known insanitary condition it is supposed that the water was the cause of the outbreak. The pipes of the Carisbrooke Water Company pass the barracks, and temporary arrangements for a supply from their main have been entered into. The question of the future supply will be carefully considered.

Surgeon-Major Sandford Moore.

In reply to Dr. Robertson, Mr. E. Stanhope stated that the Medical Director-General and the Medical Board had reported that Surgeon-Major Moore's ailment (loss of vision) was aggravated by his service.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BREESE, THOMAS T., M.B., C.M.Aber., has been appointed Medical Officer for the Puddletown District of the Dorchester Union.

CONWAY, DANIEL, Lic. Surg. Dub., has been elected Medical Officer to the County Tipperary Dispensary, vice Douty, deceased.

DUNLOP, SHULDHAM H., M.D., M.Ch. Roy. Univ. Irel., has been appointed House-Physician to the Belfast Royal Hospital, vice Caldwell, resigned.

EMMERSON, J. B., M.D.Durh., M.R.C.S., has been promoted from the Stotfold to the Biggleswade District of the Biggleswade Union.

HARGRAVE, HERBERT J., M.B., C.M.Aber., has been appointed Medical Officer for the First District and for the Workhouse of the Risbridge Union.

JAMES, ALFRED, M.R.C.S., L.S.A., has been appointed Medical Officer to the Biggleswade Union Contagious Diseases Hospital, and to the Biggleswade Union Workhouse and Infirmary, vice C. P. Stevens, F.R.C.S., L.S.A., resigned.

JONES, H. R., M.B., B.C., B.A.Cantab., B.Sc.Lond., has been appointed House-Physician to the Liverpool Royal Infirmary.

NESBITT, ROBERT ARCHER, L.R.C.S., L.R.C.P.Ed., has been elected Medical Officer for the Donaghadee Dispensary District, vice Stuart, resigned.

NOAD, ERNEST, M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Beerferries District of the Tavistock Union.

PIRIE, JOHN, M.B., C.M.Ed., has been elected House-Surgeon to the Whitehaven and West Cumberland Infirmary, vice Harris, resigned.

READ, H. G., M.R.C.S., L.R.C.P., L.S.A., L.D.S.Eng., has been appointed one of the Dental Surgeons to the Metropolitan Free Hospital.

ROECKEL, W. J., F.R.C.S.Eng., M.B., B.S.Lond., has been appointed Honorary Surgeon to the Bolingbroke Home Hospital, Wandsworth-common, S.W.

WARKE, C. L., L.K.Q.C.P.I., has been appointed House-Surgeon to the Liverpool Royal Infirmary.

WILLIAMS, C. L., M.B., C.M.Edin., has been appointed House-Surgeon to the Liverpool Royal Infirmary.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

CAPE COPPER MINING COMPANY, South Africa.—Assistant Surgeon. Earnings about £300 per annum; lodgings free, but no rations.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Resident Clinical Assistant.

CUMBERLAND INFIRMARY, Carlisle.—House-Surgeon. Salary £70 per annum, with board and lodging.

FEMALE LOCK HOSPITAL, Harrow-road, W. — House-Surgeon. Salary £100 per annum, and board and lodging.

HARTLEPOOLS HOSPITAL.—House-Surgeon and Secretary. Salary £60 per annum, with board (exclusive of beer, wine, and spirits), lodging, and attendance.

PENRITH UNION.—Medical Officer. Salary £38 per annum, with extra fees for iurgical operations, midwifery, and vaccination cases.—Vaccination Officer. A fee of 3s. in respect of each case of successful primary vaccination.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN, Waterloo-bridge-road, S.E.—Physician.

SEDBERGH UNION. — Medical and Vaccination Officer for the Dent District. Salary £20 per annum, with vacoination fees.

YORKSHIRE COLLEGE, Leeds. — Professor of Anatomy. — Demonstrator of Anatomy. Stipend £150.

Births, Marriages, and Deaths.

BIRTHS.

BROWNE.—On the 5th inst., at Norland-place, W., the wife of J. W. Browne, M.B., of a son.

COLES.—On the 4th inst., at Sydney House, Sutton-court-road, Chiswick, the wife of Donald Coles, M.D., of a son.

DRAGE.—On the 6th inst., at Hatfield, Herts, the wife of Lovell Drage, M.A., M.B., B.S.Oxon., of a son.

PHELPS.—On the 26th ult., at Ashford, Kent, the wife of Philip Phelps, M.R.C.S., of a son.

PHIPPS.—On the 7th ult., at Cape Town, the wife of Surgeon H. V. A. Phipps, Army Medical Staff, of a son (stillborn).

MARRIAGES.

BEALE—HANSON.—On the 27th ult., at St. Saviour's Church, Paddington, W., Thomas Miles Beale, M.R.C.S., to Maud Agnes Hanson, of Elgin-avenue, Maida-vale, W.

DERRY—HART.—On the 30th ult., at St. James's Church, Notting-hill, W., Bartholomew Gidley Derry, M.R.C.S., L.R.C.P.Lond., to Constance Georgina, fourth daughter of Mr. Henry Hart, of Norland-square, London, W.

DOBSON—WAY.—On the 5th inst., at St. Stephen's Church, Ealing, Leonard Charles Talbot Dobson, M.B.Lond., to Florence Sydney, daughter of T. E. Way, of Stanmer, Castlehill.

FENWICK—MANSON.—On the 6th inst., at the Church of St. Bartholomew-the-Less, City of London, by the Rev. Thomas Swan, M.A., Vicar of Thoroton, assisted by the Rev. William Ostle, M.A., Hospitaller and Vicar of the Parish, Bedford Fenwick, M.D., M.R.C.P., to Ethel Gordon Manson, younger daughter of the late David Davidson Manson, and of Mrs. Storer, of Thoroton Hall, Notts.

GEOGHEGAN—DEALY.—On the 5th inst., at St. James's Church, Kidbrooke, Alfred Osmond Geoghegan, M.D., Medical Staff, to Maud, sixth daughter of John R. Dealy, Esq., of Walton Lodge, Blackheath, Kent.

PLIMMER—ADERS.—On the 30th ult., at Norwood, by the Rev. S. A. Tipple, Henry George Plimmer, M.R.C.S. Eng., L.S.A. Lond., F.R.M.S., to Bertha Helena Aders.

THOMSON—STROMEYER.—On the 29th ult., at Holy Trinity Church, Twickenham, David George Thomson, M.D., to Melina Louise, fifth daughter of Charles Stromeyer, of Strawberry-hill, Twickenham.

DEATHS.

BARTLET.—On the 4th inst., at Ipswich, Alexander Henry Bartlet, M.D., F.R.C.S., in his 87th year.

CONOLLY.—On the 30th ult., at Church-hill-villas, Wood-green, Charles Thomas Conolly, L.R.C.S.I., L.S.A., aged 55.

CRICHTON.—On the 28th ult., at his residence in Maule-street, Arbroath, James S. Crichton, M.D.Ed., L.R.C.S.Ed.

POTTER.—On the 1st inst., at Cullompton, Devon, Samuel Reginald Potter, B.A., M.B., L.M.R.H.D., second son of the late Rev. L. Potter, Rector of Dromard, Co. Sligo, Ireland, aged 60 years, thirty of which he practised at Cullompton. Friends will please accept this intimation.

SHARPLEY.—On the 4th inst., at Louth, Lincolnshire, suddenly, Thomas Sharpley, M.D., M.R.C.S., Coroner for the parts of Lindsey, aged 55.

WRIGHT.—On April 27th, at 2, Carlton-terrace, Wynyard-square, Sydney, N. S. Wales, from apoplexy, Ellen, beloved wife of Horatio G. A. Wright, M.R.C.S.Eng., L.S.A.Lond., aged 59.

WRIGHT. — On May 10th, at 2, Carlton-terrace, Wynyard-square, Sydney, N. S. Wales, after many years of patient suffering, Annie, beloved daughter of Horatio G. A. Wright, M.R.C.S. Eng., L.S.A.Lond., aged 35.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

METEOROLOGICAL READINGS.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

URGENT CALLS AND THE CENSURE OF JURIES.

AT an inquest in Bradford lately the jury were very severe on the medical man summoned for not attending before the death of the patient. Only medical men know how misleading often is the account given of cases, and how often it errs in conveying an exaggerated notion of the case. Only they, too, can realise how difficult it is to decide between two urgent calls. The coroner in this instance remonstrated with the jury, who toned down their verdict considerably. We have no wish to apologise for undue delay in fulfilling a promise to see a patient. Rather we would urge increased promptitude, and where cases cannot be seen immediately, to refer them to other medical men.

Mr. H. A. Allbutt.—It is well and seemly for medical men, as a general rule, to act as substitutes for each other in unexpected emergencies. Such amenities increase the respect of medical men for each other, and that of the public for the profession. But the general rule will not cover all cases; and we are not prepared on the strength of an *ex parte* statement to say that the gentleman was not entitled to act independently.

A Victim.—We do not give medical advice. The ordinary medical attendant should be consulted.

W. S. W.—The licence is not accepted anywhere for the purpose name.

THE PROPOSED REGISTRATION OF FOREIGN DEGREES.

To the Editors of THE LANCET.

SIRS,—There are some points in connexion with the above subject to which I should like to draw attention. First, it seems reasonable to suppose that no Englishman would go abroad for his degree if he could get one as easily at home. Secondly, he would not seek such a degree unless he believed that at least in the eyes of the public it implied some professional superiority over his untitled brother practitioners. Assuming this to be correct, it would follow that his brother practitioners, and through them their British licensing bodies, would be injured. Also, it seems only reasonable that any supervision which the General Medical Council considers necessary for the British qualifying bodies should apply with at least equal force to those of foreign countries; and I would earnestly urge that it must be unjust to register any foreign degree, unless in the opinion of the General Medical Council it implies a higher professional knowledge than any British qualification which does not confer a similar degree. I am, Sirs, yours faithfully,

July, 1887. BRITTON

EDINBURGH UNIVERSITY.

THE Dean of the Faculty of Medicine of the University calls our attention to an inaccuracy of date of graduation given in our correspondent's letter last week. That ceremonial is always held on the 1st of August (except when that day falls on a Sunday), and not on the 2nd of that month, as stated in the letter referred to.

J. M. F.—While we sympathise with our correspondent, we do not think anything would be gained by a reference to a discussion which took place three years ago, and which we noticed very fully at the time. Slowness in promotion is an inevitable occasional result of the system adopted in our army, but we do not see how it can be avoided, except at a cost which we fear no Minister would feel justified in proposing to Parliament, or which, if proposed, would be sanctioned.

H. F. P.—Béclard died on February 16th last, and a sketch of his life and labours was published in THE LANCET of Feb. 19th. His chief work was entitled "Traité de Physiologie Humaine," which has reached the seventh edition.

General Practitioner will find an answer to his question in our last issue, page 50.

W. G. D. is thanked.

CLIMATE AS A THERAPEUTIC AGENT IN PHTHISIS.

To the Editors of THE LANCET.

SIRS,—It is with considerable interest that I have read Dr. Alexander Lindsay's article in THE LANCET of April 30th. Among the dry inland resorts Dr. Lindsay mentions that the Orange Free State is probably the best, but states certain drawbacks. My object in writing is to make known a town which enjoys all the climatic advantages of the Free State, and which is free from the objections against it mentioned by Dr. Lindsay. I mean the town of Aliwal North, which is the terminus of the Eastern System of railways of the Cape of Good Hope. It is in rail communication with the port of East London, distant some 400 miles, which is a great advantage to invalids proceeding up country. It stands at an altitude of about 4500 ft. It has excellent hotels, and living in them is cheap (about 10*s.* 6*d.* per diem). In the neighbourhood are fine hot mineral springs. It is pleasantly situated on the Orange River, which there forms the boundary between the colony and the Free State. It was only a month ago I met a clergyman there, who had come out to die, returning home after twelve months' residence in Aliwal, as he stated, "a new man." South Africa is not fashionable as a health resort; but I feel convinced that Aliwal has but to be known to be appreciated.

I am, Sirs, yours truly,

W. J. P. ROWE,
Maseru, June 3rd, 1887. Medical Officer, Basutoland.

TORQUAY AND ITS WATER-SUPPLY.

Dr. Karkeek, medical officer of health for Torquay, writes: "Just at this time, when so many towns are driven to great extremities for want of water, Torquay is enjoying the constant supply system, with plenty for street, garden, and sanitary purposes, and enough stored in its reservoirs to last until Christmas. The town has spent enormous sums in procuring a large supply of pure water, and now it is reaping the advantages of its judicious expenditure."

Anxious.—It is not our practice to answer communications from laymen, especially when they involve charges against medical practitioners which rest on *ex parte* statements.

Dr. H. W. Phillips.—We cannot decide until we see the paper.

VOMITING PERSISTING FOR YEARS.

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent who has treated unsuccessfully a case of vomiting for thirteen years, I beg to state that I have had a similar patient under my care at the St. George's Dispensary for many years, whom I have treated with partial success with koumiss (alone) as food, sherry as a stimulant, and ingluvin, from five to ten grains, before each meal between thin slices of bread-and-butter, or in a spoonful of water.

I am, Sirs, yours truly,

Richmond-terrace, S.W., July 4th, 1887. HENRY SUTHERLAND.

HOW TO TAKE CASTOR OIL.

The Monthly Magazine of Pharmacy quotes the following suggestion as to taking castor oil from a French source:—"Take a half-glass of frothy, sparkling beer, mix the dose of oil with it, and whip it up so as to make it froth strongly. The oil thus becomes intimately mixed with the froth, and if only the latter is drunk, he says, neither the taste of the oil nor that of the beer is perceived."

Curious.—Mr. Crookes appears to have found that seven, or perhaps nine, kinds of atoms are present in the substance known as yttrium. Other illustrations of the hypothesis of the same observer will be found described in an article which appeared in our impression of the 25th of February last.

Mr. J. M. Lund.—Some comments on the case will be found in THE LANCET of April 2nd last.

THE ABUSE OF BROMIDE OF POTASSIUM.

DR. GRELLETY, writing in *Le Practicien*, mentions that he has frequently met with cases where diabetics, a class of persons who, as he remarks, are especially prone to read medical literature bearing on their malady, having discovered that bromide of potassium has been highly recommended in diabetes, have commenced to prescribe this drug for themselves, and have taken enormous quantities, thus doing themselves a great deal of harm. Dr. Grellety is convinced that a good many of the boils which are met with in diabetic patients, and which are generally attributed to the disease, owe their origin rather to the prodigious doses of bromide which the patients have been taking surreptitiously. He remarks that M. Bernier is in the habit of always prescribing arsenic combined with bromide in the proportion of a drop of liq. arsenicalis to each drachm of bromide, in order to neutralise the undesirable tendency of the latter to produce cutaneous affections. He concludes by advising all practitioners before prescribing bromide to examine carefully into the condition of the patient's skin, circulation, digestion, and kidneys; and, if he find evidence of deficient transpiration or any urinary trouble, to proceed with great caution. Again, it is well to endeavour to obtain information as to whether the patient has ever taken bromide, and, except in cases of urgency, small doses only should be given at the commencement.

Mr. John J. A. Ray.—We can understand our correspondent feeling hurt at the letter he forwards us, and we quite believe that he acted in good faith in printing the testimonials and list of operations, &c. The form of the latter is, however, somewhat startling, and hardly to be approved in connexion with an application for an assistantship or locum tenency.

Alpha.—The case is weak. We would not recommend legal proceedings.

"PHOSPHATE OF LIME TREATMENT IN LOCAL TUBERCULOSIS."

To the Editors of THE LANCET.

SIRS,—In your Vienna correspondent's report, on the 2nd inst. (p. 44), of the above treatment he omits to state that in the prescription No. 1 for injections the solution *must* be sterilised. There is also an omission of a line from the formula. After the words "Deinde sensim adde" should follow "Acid. phosphor. q. s. ad solution. perfect. filtra; adde: Acid. phosphor. dil., 0·6," &c. (*Wien. Med. Pr.*, Juni 12, 1887, p. 839). Herr Ernst Freund says: "The solutions which Dr. Kolischer used as injections were, in accordance with his wish, most carefully sterilised. The acid phosphate of calcium having been separated into phosphoric acid and secondary phosphate of calcium (which itself separates) by means of boiling, a considerable precipitate in the solution No. 1 was apparent during the process of sterilising, which, however, after standing several hours at the ordinary temperature of the room, again dissolved." (*Op. cit.*)

I am, Sirs, your obedient servant,

New Cavendish-street, W., July 4th, 1887. WM. MARTINDALE.

"LE SCALPEL."

WE have to congratulate our Belgian contemporary on having completed its fortieth year. *Le Scalpel* is published at Liège under the able editorship of Dr. A. Festraerts, and always takes up a strong position on behalf of the profession when it is in danger of being imposed upon. It also speaks with no uncertain sound on the high standard medical men are bound to maintain in a moral as well as in a scientific sense.

Mr. A. W. Stirling (Grays).—An abstract of the thesis would no doubt be interesting. It should not exceed three columns in length.

A MIDWIFERY CASE.

To the Editors of THE LANCET.

SIRS,—On May 3rd last I attended Mrs. B—— in her seventh confinement. On the birth of the child's head I discovered that the cord was twisted once round its neck, and on trying to bring it over the head I found that I could not on account of its shortness. The pains were very strong. Fearing inversion of the uterus or sudden detachment of the placenta from the uterine walls, I asked the patient to cease bearing down. At the same time the head and shoulders, which were born, were kept firmly back. I then called for a pair of scissors, and divided the cord, previously tying the end next the umbilicus. Had I not acted promptly in this case the placenta might have been either forcibly torn from its attachment, and thus have caused post-partum hæmorrhage, or inversion might have occurred. I did not measure the cord.

I am, Sirs, yours very truly,

Peckham, July 2nd, 1887. ED. T. YEATES, L.R.C.S.I., &c.

ONE EFFECT OF CHEAP QUININE.

IT is said that the present low price of quinine and cinchona has caused the collection of the bark in Guayaquil to be so unremunerative that this industry has been almost given up there.

C. M.—The holder of the degrees mentioned has no legal entitlement to styled "Dr."

Lectures ON INJURIES OF NERVES.

Delivered at the Royal College of Surgeons,

BY ANTHONY A. BOWLBY, F.R.C.S. ENG.,

SURGICAL REGISTRAR AND DEMONSTRATOR OF SURGICAL PATHOLOGY AT ST. BARTHOLOMEW'S HOSPITAL, HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS.

LECTURE III.—*(Concluded.)*

TREATMENT OF NERVE INJURIES.

Causes of failure of primary suture of nerve.—I have already expressed my opinion that "if the nerve ends have been carefully coapted and kept in position, restoration of function will ensue in the great majority of cases," but I have no doubt that in some instances no such restoration occurs. The causes of failure are more than one, but those on which I would lay most stress are "sloughing of the nerve ends" and profuse suppuration in the wound. The deleterious effects of sloughing are so obvious that I need not enlarge upon them. It is evident that if portions of the nerves are destroyed union is not to be expected. This sloughing was the probable cause of failure in a case of ulnar suture at St. Bartholomew's Hospital, and also in the case of suture of the peritoneal nerve recorded by Iefremowsky. In cases where suppuration is profuse, portions of nerve may be destroyed by ulceration, and even if they escape this fate they are liable to be strangled and compressed by dense scar tissue, as in a case recorded by Busch-Madelung. But not only may the nerve ends be destroyed by the suppuration, the sutures which hold them in apposition may likewise be liquefied, and thus the ends may become separated. I am inclined to think that this accident most probably occurred in the two cases of failure of suture of the ulnar observed by myself, but it is quite possible that pressure by scar tissue may have caused the continuance of the paralysis. The treatment of cases of failure of primary suture is sufficiently clear. In any case where sufficient length of time has been allowed to elapse without restoration of function, the nerve should be exposed at the seat of injury. If its continuity is not interrupted, it should be freed from scar tissue, then thoroughly stretched to free the individual fibrils yet more. If the ends have become separated from any cause, the operation of "secondary suture" should be performed as described in the following pages.

Treatment of complicated wounds of nerves.—In connexion with this subject I shall allude but briefly to two complications: 1st, cases in which the nerve ends are much lacerated and contused; 2nd, cases in which the ends cannot be brought into contact. With regard to the first, the proper treatment, in my opinion, would be the resection of such an amount of nerve as seemed too much damaged to recover, followed by stretching of the proximal and peripheral ends and fixation by suture. That the most satisfactory results may follow such treatment, a case I have already mentioned of a wound of the median nerve supplies ample proof. Here there was a great deal of laceration of the soft parts, and I found it necessary to remove about one inch of nerve which had been almost completely separated from both the upper and lower ends. I did not meet with any material difficulty in bringing the cut surfaces into apposition, and, after fixing the hand in a flexed position on a splint, the case resulted in union by first intention. The second complication I have mentioned is much more serious, for where the ends of the divided nerve cannot be brought into apposition on account of too extensive loss of nerve substance, the prognosis cannot be very favourable. Létiévant has recommended that one of two operations should be performed. First, that the peripheral ends should be sutured to a freshened surface of some neighbouring [illegible], that the proximal end should be [illegible] sufficient extent, a cross section [illegible] the nerve at the highest point [illegible] carried, and then that the split portion should be turned down and placed as a sort of graft between the [illegible]. I am not aware that either of these operations has ever been put into actual practice, but should view each with but little favour. The second suggestion especially seems to be of more than doubtful value, for the split portion would really be completely separated from each end, and in my opinion would probably slough. In a case where an inch or two of nerve had been destroyed and I was unable to bring the ends into apposition, I should pass sutures through them, and bring them as close as possible by the aid of stretching and of position. In this way further retraction would be prevented, and the two cut surfaces would, at any rate, be fixed in the same plane. I have already detailed cases where union has occurred after excision of several inches of nerve independently of suture, and although I should not give a favourable prognosis, I believe that such treatment would afford the best prospect of recovery. Some experiments by Vanlair[1] are of interest in connexion with this subject. This author details how he resected three centimetres of the sciatic nerve of a young dog, brought the ends as near to one another as possible with sutures, and enclosed them in one of Neuber's decalcified bone drainage tubes. The wound healed readily, and four months later an examination of the seat of injury showed a reunion of the divided nerve. It is evident that the only value this treatment possesses is derived from the fact that the cut ends of the nerve are prevented from becoming adherent to the surrounding tissues, or compressed by the cicatrix.

Secondary suture of nerves.—The operation of secondary suture is performed at some time after the infliction of the original injury, generally in cases in which no attempt has been made to secure primary union of the divided nerve. It may be performed either before the wound has healed, or else after it has cicatrised. The indications for such an operation are afforded by the presence of symptoms pointing to the conclusion that a nerve has been divided, and has not united. These symptoms I have already alluded to and described in detail, and will only point out that, as I have already insisted, it is not sufficient to examine the sensation alone of parts supplied by the nerve in question—the conditions and electrical reactions of the muscles are of as great if not of greater importance. With respect to the advisability of performing this operation, I would say in its favour all that I have already said in connexion with "primary suture." In all cases in which a surgeon believes that a divided nerve has not united it is his duty to attempt the suture of the separated ends. In performing the operation it is of prime importance that the parts should be as bloodless as possible, and to obtain this end the use of Esmarch's bandage is most advisable. The limb having been exsanguinated, an incision should be made through the scar in the line of the wounded nerve, the ends of which must be carefully sought. Very frequently these ends have become separated by a considerable interval, and it is frequently necessary to prolong the wound to a much greater extent than originally appears necessary. The upper end is usually the more easily found, for it is not atrophied, and its bulbous extremity is frequently very prominent. The latter is generally closely adherent to the surrounding scar tissue, and from this it should be carefully but completely separated. The search for the lower end is sometimes very tedious and difficult. It is often much atrophied, and is liable to be displaced from its normal situation by contraction of the neighbouring scar tissue. When any difficulty is experienced, it is best to search for the nerve below the seat of section, and having found it at a place where it is not hidden or dragged aside, to trace it thence to the scar. From the latter it must now be separated in a similar manner to the upper end. The extremities of the cut nerve having been thus exposed, the next question to arise is as to the amount which should be resected. On this point I am very clear. The section of the upper end should be carried through the uppermost part of the bulb, close to the normal trunk. At this point there are numerous young nerve fibres, and the tougher tissue of the bulb affords an excellent hold for the sutures. In dealing with the lower end it should be remembered that its whole length is in the same condition of degeneration or of regeneration throughout. Manifestly there can then be no good done by cutting off successive sections in the hope that the cut surface may look more healthy than that which is seen on the first resection. All that should be done is to cut away the extreme end, which, being matted

[1] Archiv. de Phys., 1882, vol. x. p. 595.

Digitized by Google

with fibrous tissue and compressed by the surrounding scar, is very likely to contain no nerve tubules or elements of any kind. It is seldom necessary to remove as much as a quarter of an inch, and, however unhealthy the section may look, no good is ever to be gained by a further sacrifice. The nerve ends should be as little pinched or bruised as possible, and after section should not be held by forceps. If it is necessary to use the latter, they should be fixed in the sheath. In cases in which there has been much separation of the cut ends an additional inch or more may be gained by a thorough stretching of each extremity. When this is done, it is often advisable to remove the Esmarch's bandage, for if this be applied immediately above the seat of operation, it will tend to greatly limit the amount of length to be gained by stretching. As to the material for suture and the best method of passing sutures, I have nothing to add to that which I have written in treating of the subject of primary suture.

Summary of cases of secondary nerve suture.—The value of the operation of secondary suture can only be judged by a clinical study of patients, and by reference to recorded instances. Time does not permit me to describe in detail the clinical features of the various cases I have watched, or to do more than tabulate the records of other surgeons. For the present, therefore, I must ask you to accept this summary.

The following cases of secondary suture were performed in St. Bartholomew's Hospital up to December, 1885:—

Median nerve: Successful, 1; partially successful, 4; failure, 1—total, 6. Ulnar nerve: Successful, 2; partially successful, 5; failure, 3—total, 10. Musculo-spiral nerve: Successful, 1. Median and ulnar nerves: Partially successful, 1. Grand total, 18—viz.: Successful, 4; partially successful, 10; failures, 4.

Cases of secondary nerve suture recorded in surgical literature up to December, 1885:—

Fifth cervical nerve: Successful, 1. Median nerve: Successful, 3; partially successful, 5; failure, 3—total 11. Ulnar nerve: Successful, 5; partially successful, 1; failure, 3—total, 9. Musculo-spiral nerve: Successful, 11; greatly improved, 3; failure, 2—total, 16. Radial nerve: Successful, 1. Median and ulnar simultaneously: Successful, 1; partially successful, 2; failure, 3—total, 6. Median and radial simultaneously: Partially successful, 1. Sciatic nerve: Successful, 1; improved, 1; failure, 1—total, 3. Popliteal nerve: Improved, 1. The above cases give a grand total of 49, of which 23 were successful, 14 partially successful, and 12 failures.

If the cases recorded by myself be added to those recorded by other authors, the totals will read thus: Successful, 27; partially successful, 24; failures, 16—total, 67.

In drawing up the above summary I have been very careful not to include amongst the "successful cases" any but those in which there appeared to be either a complete or almost complete restoration of function. Many of the St. Bartholomew's cases which I have placed under the head of "partially successful" might with almost equal fairness have been placed under the first heading, and I have no doubt that in time they will deserve such promotion. In the cases recorded by other authors I have often had much difficulty in deciding whether to place the case under the "successful" or "partially successful" class. I have in cases of doubt generally placed them under the latter; but where the details are few, and where, as is often the case, the return of sensation alone is noted, it is impossible to accurately estimate the value of the individual operation. But although I have taken all the care possible in this summary, as in that of cases of primary suture, the table, like the [illegible] is misleading. The cause in each is the same. [illegible] of the first things that strikes one on a consideration of the cases noticed by myself is the considerable [illegible]me that frequently elapsed between operation and [illegible] improvement. More especially is this the case [illegible] with the restoration of muscular power. This is a point of such importance that I shall venture to still further analyse the reported cases.

Of the cases of secondary suture of the median nerve at St. Bartholomew's, in the one recorded as a success the latter was not attained for more than four months and a half after the injury. In the two cases of successful suture of the ulnar nerve nearly two years elapsed in each before restoration of function was perfect. In the one case of suture of the musculo-spiral power did not commence to return for three months, and almost a whole year elapsed before motor power was perfected. In the cases of secondary sutures, in which successes have been recorded by other surgeons, the time that elapsed in several cases before complete restoration resulted was, respectively, one year, two years, a year and ten months, a year and a half, one year, two years, three years, one year and a half, &c. In many cases a much shorter time was requisite, but these instances are sufficient to show that because restoration of power is not complete after a few months this is no reason for considering the case a failure, or for supposing that further improvement will not take place. All that I have said on this subject, when writing of primary suture, applies here equally well, and I would now point out that, with these facts to work upon, a further investigation of the cases recorded by myself and others must result in the inevitable conclusion that in many of the cases which are included amongst those of "failure" or of "partial success," a further improvement was to be expected, and would probably ensue.

Thus, if we look at the cases I have placed under the heading of "partially successful," we shall find that of my own those of median suture were only under observation for nine months, eight months and a half, five weeks, and five months respectively. Those of ulnar division for four months, two years, one year, one year and a half, and six months. That of the median and ulnar simultaneously for a year and a half. All these patients are still under observation, and from the way in which they all have improved and continue improving I confidently anticipate a favourable termination. In the cases of suture of the ulnar nerve, in one there was no sign of improvement for a year and a half (after that it was rapid), in another none for a year, whilst in the case of "improved" in the suture of the median and ulnar nerves there was no change for a year and three months, and then rapid restoration of power. Seen in this light the cases in which only a partial success or else a failure is recorded by other surgeons assume a very different aspect.

Of the "partially successful" cases those of median suture were under observation for only twenty-six days, one year, several weeks, six weeks, and seven weeks respectively. That of ulnar suture for five weeks. Those of musculo-spiral suture for two and a half months, ten weeks, and two months. Those of suture of the median and ulnar for seven months and for five weeks. That of the sciatic for a doubtful time. That of the popliteal for three years. Of the cases of "failure" recorded by other authors, those of median suture were kept under notice for eight weeks, a few weeks, and in the third case for no special time mentioned. Those of suture of the ulnar for two months, a doubtful period, and for eight months respectively. Those of musculo-spiral suture for twenty-six days and for a short time. Those of suture of the median and ulnar simultaneously for six months, three months, and a few months. That of the sciatic nerve for one year. Thus of all these cases of recorded "partial success" or "failure," but one—and that a "partial success"—was observed for more than a year, whilst most of the others were not seen for more than a few weeks after suture. It is not possible to consider these results as final. I have shown that in cases kept under notice for a sufficient length of time recovery may ensue where failure has been expected. Of the cases that I record most were discharged from hospital but little better than on admission, yet in almost all—in all, in fact, but two—improvement ensued at a later date.

Most of what I have just written is, as I said at the commencement, in reference to the return of motor power, and if we consider that at the time of suture the muscles were in most of these cases in a state of advanced degeneration and atrophy, I think that the long time required for restoration is only what might be expected. The nerve has to be rejoined, and after that the muscle has to be remade. This restoration of muscle is, indeed, one of the most marvellous evidences of recuperative power ever met with in the human body. Muscles, of which there scarcely appears to be any remains, may be entirely restored in bulk and in power. It is wonderful that this occurs at all, and that it should occur rapidly is not to be supposed.

In the cases in which sensation returns, the most varying times are required for its restoration. In some cases there was restoration of sensation within twenty-four hours of operation, and in others within two or three days. In some again, sensation did not return for many months; in others it required a year or more for its further development. It is very noticeable that in some of the St. Bartholomew's

Digitized by Google

cases, as well as in a few of the others, a rapid return of sensation after operation was followed by an equally rapid loss after a few days of hope.

How is this rapid return to be accounted for? It has been noticed to occur at almost all times after section at intervals of a few weeks or of many months. For my own part, I do not doubt that it implies a restoration of continuity between the divided ends of injured axis cylinders. Either some of the latter have not entirely degenerated, or, as in the cases observed by myself, they have again regenerated. This is, in my opinion, the only rational explanation. French authors, on the other hand, believe that the return is due to some reflex changes which ensue in the other nerve trunks as the result of the section of the bulbous extremity of the proximal wounded end. What these changes are they do not suggest, much less prove, and, for the present at least, I shall continue to be sceptical as to their existence. It has been argued that it is not possible to explain restoration of sensation by a re-establishment of continuity of the divided axis cylinders if you do not find the said axis cylinders in the resected portion of the peripheral end. At first sight this appears plausible. It is nothing more, and I certainly would not be prepared to say that because I could find no axis cylinders in a tag-end about one-eighth of an inch in length therefore they did not exist. I can conceive nothing more difficult than to search for such remnants of nerve tissue in the end of a wasted nerve mingled with the products of inflammatory action. The only rational explanation of a return of function after secondary suture is that it is due to a reunion of the divided axis cylinders, difficult as this may be to explain, in view of the probable condition of degeneration of the peripheral end.

How then shall we explain the not infrequent disappearance of the recently restored sensation? My own experience is that this disappearance is usually coincident with the establishment of suppuration or of inflammatory swelling about the wound, and I consider that in such cases the recently united nerve ends become separated for the time by inflammatory exudations. This lost sensation may again return and in time become perfected.

There is, however, another point of considerable interest yet to be noticed—namely, the rapidity with which regeneration sets in after the ends have been reunited. Looking at what we know of the changes occurring in the periphery of a divided nerve, we might almost be led to expect that, in the most favourable cases, the nerve suture would but place the divided ends in a favourable position for union to occur after such a time as is required for the processes of degeneration and regeneration to be completed. But the cases before us show very clearly that the reunion of the proximal and peripheral ends hastens most materially the reparative changes in the latter, so that instead of a year or more being required for the restoration of the nervous function, this is often re-established within a few months of the operation, even when the latter has taken place long after the original accident, and, consequently, at a time when the peripheral fibres are supposed to be in their most degenerate condition. The exact manner in which this is brought about has not yet been demonstrated, but I should suppose that the increased rapidity of repair is simply due to the reunion of the nerve fibres with their centre of nutrition. There can be no doubt that at the time of suture the nerve fibres may be in an extremely degenerate condition, the myeline being destroyed and many of the axis cylinders absent, and yet that symptoms of union may occur within the first twenty-four hours, as in the cases to which I have alluded.

Prognosis of cases of secondary suture of nerves.—Speaking generally, I believe that the prognosis of cases of secondary nerve suture is that great improvement is almost certain to follow, and that success is to be expected in the majority of instances. I believe that this prognosis is justified by the histories of the cases I have mentioned. Naturally, perhaps, I am influenced greatly by the conditions of the patients I have myself observed, and when I have seen one after another improve, often after a year or two of paralysis and of deformity, I am inclined to think that if the nerve ends are still in contact there is yet hope for all. I have already endeavoured to explain the occurrence of many of the reported cases of failure, and shall again refer to this subject. As to the length of time that may be required for this restoration of function, nothing definite can be said; but where there is great muscular atrophy the surgeon may feel sure that a rapid restoration of power is a physical impossibility. I would give up no case until after several years. As in cases of primary suture I believe that restoration is both more rapid and more perfect in the young than in the old, that it is more rapid in warm weather than in cold, and that certain nerves—the musculo-spiral especially—are more prone to unite than are others. I would refer for further evidence to what I have already said on the subject of primary suture. In the case of secondary suture, however, a question has to be considered that does not arise in the case of suture of recently divided nerves. It is, What is the influence of the length of time that elapses between the injury and the suture? I confess that, at first, I was disposed to think that the length of time exercised more influence than I am at present disposed to attribute to it. Nevertheless, I still believe that it may in certain cases materially influence the result.

As I have already pointed out, the peripheral end may be in varying stages of regeneration or degeneration at the time of suture, and although it might perhaps be expected that a corresponding difference in the rapidity of union could be established, and though I myself had expected to find such a difference, I cannot say that my expectations have been realised. It certainly cannot be said that reunion follows more rapidly after suture performed a few weeks from the injury than after the same operation some months after section. Neither is the reverse true. I believe that a careful study of the recorded cases will show that, within at any rate the limits of a year, the time after injury at which suture is performed does not materially influence the subsequent rapidity or perfection of the union. My own experience is not yet sufficient to allow me to state definitely whether regeneration of muscle is to be expected in patients on whom the operation of secondary suture has been performed more than a year after the original injury. I have, however, seen two cases, in addition to those I have summarised above, in which marked restoration of sensation has followed upon secondary suture performed respectively two years and four years after the nerve was first divided. Both of these cases are yet recent, and muscular power is not at present definitely improved, but I am not prepared to say that it will not yet return.

Of the cases published by other authors, in one suture was performed fourteen months after injury; the case is recorded as a failure, but the patient was only kept under observation for three months after operation, so this report cannot be considered final. In one case the operation was performed after two years and a half. This, again, was a failure, but the patient was only observed for twenty-six days. In one case secondary suture of the sciatic was performed nine years after injury, with resulting improvement. In one patient a restoration of sensation followed suture of the median fourteen years after injury. The case was reported by Tillaux seven weeks after operation, and no improvement in muscular power is noted. In the latter case it is important to observe that the peripheral end was much atrophied, and further that in the resected portions no nerve elements were found, though on the latter fact I do not lay much stress. These are the only four cases in which suture was performed more than a year after injury.

The question then arises, Will the function of the muscles be restored if suture is performed at any length of time after injury? That restoration can occur in cases operated upon as late as a year after section there can be no doubt; but the published cases of suture after this time being only four in number are scarcely sufficient, nor are they reported with sufficient detail to allow of a definite answer. This much at any rate may be said: In no case has complete restoration of function yet ensued when operation has been delayed more than a year; that complete restoration is impossible I will certainly not pretend to say, but I may draw attention to certain facts which are, I think, opposed to such a belief.

In an earlier part of these lectures, in the section devoted to pathology, I have shown that some at least of the nerve fibres in the proximal end degenerate after section, and have given my reasons for believing that after the peripheral end has become in part regenerated it may again degenerate if union with the proximal extremity does not occur. It is, of course, possible that even after this, reunion with the proximal end may result in another regeneration, though such appears at least doubtful. At what period of time this second degeneration occurs I cannot say, and for my evidence in support of this theory I must refer to the section on pathology. But whilst a degenerate condition of the lower end may possibly prevent the success of secondary

Digitized by Google

suture there is another condition, altogether apart from that of the nerve itself, which has been overlooked by other writers, but which, I think, is of far greater importance.

It has been noticed by Dickinson and other writers that, in cases of amputation of the limbs, atrophic changes ensue after the lapse of years in the spinal cord; and Vulpian has further demonstrated that similar changes occur if instead of amputation the nerve trunks of the extremity are divided. Now, the changes that are described include serious destruction and atrophy of various parts of the spinal cord, and more especially of the large motor cells. These cells are the trophic centres of the muscles, and once they are destroyed it is very doubtful whether they can again be reformed. For this reason I think that after many years of solution of continuity of a nerve, it is most improbable that motor power can be restored by the operation of secondary suture. That there may be some return in sensation I can believe, and indeed the case by Tillaux seems to put this question out of doubt; but further evidence is required before any definite time can be assigned beyond which suture is useless. Meantime, I would never refuse to perform the operation merely because theoretically a good result seemed improbable.

Causes of failure of cases of secondary nerve suture.—In dealing with the causes of failure of primary suture of nerves I have already stated my opinion that this is frequently due to sloughing or extensive suppuration in the wound. The same causes may also prevent success in secondary suture. In the only case of secondary suture of the median, under my own observation, which resulted in failure, the wound, and probably the nerve, sloughed. In those cases where there was much suppuration union was generally more tardy. In a case recorded by Mr. Pye of secondary suture of the ulnar, the cause of failure was found to be the compression of the nerve by scar tissue, and after the latter had been separated, restoration of function was rapid. This case is quite analogous to that recorded by Busch-Madelung of a similar operation with a similar result for a case of primary suture of the musculo-spiral, in which the functions were not restored. The giving way of the suture also may undoubtedly cause non-union, and thus we find that all the causes of failure present in cases of primary suture may also bring about a similar result in those of secondary suture. The treatment also of cases in which secondary suture has not resulted in union is similar to that I have recommended in cases of failure after primary suture. The sutured nerve should be exposed. If its ends have become separated they should again be sutured. If the nerve is compressed by cicatricial tissue, or is unduly adherent, it should be freed from pressure and stretched.

Treatment of cases in which the resected nerve ends cannot be brought into apposition.—In a certain number of cases of old nerve injury it is impossible to bring the ends into apposition on account of their extreme retraction. Such a condition is fortunately not a common one, for the operation of stretching, followed by careful attention to position, is usually sufficient to overcome the retraction. I have never seen it necessary to abandon an operation from this cause alone. The question is, nevertheless, one of much importance for the few patients who may be in such an unfortunate position, and various remedies have been suggested. First, there are the two suggestions of Létiévant, to which allusion has already been made in dealing with the question of treatment of recent nerve wounds, where much nerve substance has been removed by injury. The treatment alluded to as recommended by this surgeon consists in either suturing the lower end on to a freshened surface on a neighbouring trunk, or else in splitting the upper end, and turning down a portion by way of a graft. Although I do not think that such treatment is to be recommended in cases of recent wounds, where by other means union may be obtained, yet I am not disposed to altogether condemn either of these methods in dealing with a case in which all attempts at union have failed, and in which the parts are left in a hopelessly crippled condition. Of the two suggestions I should prefer to practise the latter, as it does not involve any interference with neighbouring healthy nerve trunks.

The next suggestion is that the space between the separated end should be filled by "grafting" into it a portion of fresh nerve taken from an animal. The operation of nerve grafting and transplantation has been experimentally performed by Gluck and Johnson, and according to them with success. As far as I am aware there are only two cases on record of this operation having been performed on man for the relief of injury. The first case is recorded by Tillmans in the *Berlin. Klin. Wochen.* of June 8th, 1885. The patient was a woman aged twenty-two, in whom the median and ulnar nerves had been divided. On the operation for secondary suture being performed, the divided ends were found to be separated four and a half centimetres. The operator therefore grafted portions of nerves between the resected ends. Sensation began to return at the end of four weeks, and motility at the end of nine. The other operation was performed by Kaufmann. In a case of paralysis of the musculo-spiral, following on an injury to the nerve in an operation for removal of dead bone from the humerus, Kaufmann practised on Dec. 28th, 1880, the operation of nerve grafting. After having freed and refreshed the two ends of the musculo-spiral nerve there was left a separation of more than four centimetres. In order to free the gap, he transplanted a portion of the sciatic nerve of a dog. In the middle of the following February it was still impossible to pronounce on the result of this operation.[2]

In the following case the separation of the resected ends was overcome in another way—namely, by resecting a portion of the humerus, and so shortening the arm; the case is recorded of Bergmann.[3] The patient was a lad, aged fifteen, who had been severely wounded in the right upper arm by a circular saw. The wound had healed in about ten weeks, but the boy had lost all power of motion, and all sense of touch in his right arm and hand. An operation was performed in which the divided nerve was exposed, and it being found impossible to bring the ends together, two inches of the humerus were resected. The case has not yet been recorded by the operator, and it is not mentioned in the *British Medical Journal* which nerve was divided, or what was the result.

With regard to the question of the best operation to perform in any case occurring in actual practice, I may say that I do not consider it advisable to perform so severe an operation as resection of a portion of bone in order to bring the divided nerve ends into apposition. Neither am I at all favourably disposed towards the grafting of portions of nerve from animals. I believe that in most cases the best thing to do would be to resect the ends, to bring them into as close apposition as possible, and then to enclose them in a Neuber's decalcified tube. If I did not do this I should follow Létiévant's advice, and turn down a piece of the proximal end after splitting it, in the manner I have already described.

Clinical Lecture
ON
THE JAUNDICE OF INFANTS.

BY JOHN W. BYERS, M.A., M.D.,
PHYSICIAN TO THE BELFAST HOSPITAL FOR SICK CHILDREN AND PHYSICIAN FOR DISEASES OF WOMEN TO THE ROYAL HOSPITAL, BELFAST.

GENTLEMEN,—From the earliest records which we possess of the study of medicine we find that jaundice has at all times been a most interesting subject, while the most careless observer must be arrested by the striking appearance of the person affected. The circumstance that jaundice is not in itself a disease, but merely a symptom depending on a great variety of causes, presents the careful and scientific physician with problems of surpassing importance; for until in any given case he can unravel the cause of the jaundice he must feel that both his prognosis and treatment may be entirely at fault. As you have seen at this Children's Hospital and at the Royal Hospital, jaundice may be met with at all periods of life. It is, however, to that form of jaundice which occurs among infants that I wish to-day to direct your attention, a subject about which your ordinary text-books give you but scanty information. My remarks will be based on the experience I have gained in this hospital and in private practice during the past six years. I propose to say a few words about the various

[3] British Medical Journal, 1884, vol. ii., p. 1065.

Digitized by Google

varieties of infantile jaundice, and the line of treatment to be adopted in each. Let me first, however, draw your attention to a condition of matters met with in the new-born child to which, I think unfortunately, by some the term "icterus neonatorum" has been applied. On the second or third day after birth, on visiting your lying-in patient, you will sometimes be told in alarm or in wonder that "the baby has the jaundice," and in confirmation of this statement you will be asked to look at the yellow colour of its skin. If, however, you observe with care you will note that the conjunctivæ of its eyes are white, and on inspecting the diapers you will see neither pipeclay motions nor stains of high or saffron-coloured urine; in a word, there is no evidence of jaundice present except the apparent yellowness of the skin. Those of you who have taken out your midwifery cases know that at birth the surface of the infant's body is covered with a white or yellow adhesive coating—the vernix caseosa—which is composed of sebaceous and epidermic cells and fat. If you have not already observed this circumstance, note carefully at the first opportunity you have the condition of a new-born infant's skin from which this vernix caseosa has just been washed off. You will see that it is of a rosy-red colour, and in a short time, if with your finger you press the skin so as to empty the small superficial bloodvessels, you will see a distinct trace of a yellow colour which gradually increases. This begins on the second or third day, lasts about a week, and is generally gone about the tenth day. You will as a rule observe that this apparent yellowness is most marked just in those places where the redness has been greatest. Now there is one point in reference to this form of pseudo-jaundice which is worth noting. As you are aware, the usual plan is to tie the umbilical cord as soon as the child has breathed freely, but the experiments and observations of Budin,[1] Schücking,[2] Engel,[3] and others have shown that if you delay ligaturing the funis until all pulsation has ceased the child will receive a certain quantity of blood, which by early tying would be left in the placenta. Further, by adopting this method children are more vigorous and active. They lose less weight immediately after birth, and subsequently are said to increase in weight with greater rapidity than those children in whom early torsion of the cord has been practised. The advantage of the late ligature of the funis is very marked in premature children, as it has been ascertained that the mortality in their case with the adoption of this practice is only one-half what it is when the cord is tied early. During the past two years I have, in my obstetric practice, adopted the plan in all cases (except in a few where, owing to the mother's condition, it was necessary to expedite the delivery of the placenta) of waiting until all pulsations in the funis have ceased before putting on the ligature, having been convinced by the observations and experiments of the authors I have mentioned, as well as by the practice of the continental lying-in hospitals, that such a method is better for the child than tying the cord as soon as it cries or breathes freely. Since adopting this practice I have met with more of these cases of apparent jaundice, which is, however, in no way detrimental to the child, and which is probably due to changes in the circulation of the skin and gradual disintegration of the abundant blood cells. The fading of the rosy redness which comes on soon after birth in its gradual changes leaves behind it a yellow tinge, like that seen in a vanishing bruise.

We now, gentlemen, come to the discussion of real jaundice in infants; and the cases I have seen in this hospital and in private practice are sharply divided into two classes: in the one, the jaundice, as a rule, is mild and the children recover, while in the other group the jaundice becomes more intense until the fatal termination. I have met with several cases where the discolouration of the skin, conjunctivæ, and the white motions with high-coloured urine have been present, this condition of matters, lasting from about a week to ten or twelve days. The children seemed to suffer little, and many of them were first-born children. [illegible] that exposure to cold or a vitiated [illegible] cause of the disease, and in support of [illegible] Bhottinda Lying-in Hospital jaundice [illegible] Paris foundling hospitals nearly all suffer from it, the reason being that in the former hospital they are properly cared for, while in the latter the air is bad and the children are exposed to cold. As to the exact causation of this mild form of jaundice we are still in the greatest doubt, because fortunately the children, as a rule, recover; and consequently autopsies are rare. Different observers have given very diverse explanations. While Virchow thinks this form of icterus is due to a gastro-duodenal catarrh, Frank believed it is the prolonged retention of the meconium which is the cause. Cohnheim held that the bile secretion was increased rapidly after birth to such a degree that it could not be eliminated, while Frerichs taught that it was due to changes in the hepatic circulation. An explanation put forward by Birch-Hirschfeld is accepted by some as accounting for the jaundice. This observer has shown that the vessels in the notch of the liver, and also for some distance within that organ, are surrounded by a layer of fibrous tissue. This gets œdematous and becomes swollen, when, owing to a prolonged or difficult labour, there is interference with the hepatic circulation, and by its compression gives rise to obstructive jaundice. I mention these various theories, but do not think that any one will cover all the cases. There is a ready method by which you can tell whether the jaundice is real or apparent. If a piece of white linen fastened round the child's loins be coloured yellow, then you may be sure it is a case of true jaundice.

I will now ask you to consider the very important group of cases where the jaundice gradually deepens and the infants die; and the following cases are types of the various conditions which may give rise to fatal jaundice.

CASE 1.—I show you to-day a small, shrivelled, miserable-looking infant three weeks old. You see it is intensely jaundiced; its eyes and skin are yellow, and in the upper half of its body note the presence of some purpuric spots. You also see blood oozing from its mouth. The umbilicus is normal. You see its diaper is stained a yellow hue. Its mother tells us that at birth it was healthy-looking, but at the beginning of the second week its skin and eyes "turned yellow," its motions became white, and its water high coloured; and all these symptoms have gradually deepened. It is a full term child, but the mother has had a premature baby, and from what she tells us of her having had a sore throat, rash, and falling off of the hair, there is a clear specific history. We look upon the jaundice here (especially from the history) as being due to some form of syphilitic inflammation or growths compressing the bile-ducts (the peri-pylephlebitis of Schüppel), and our prognosis is of the worst kind. (This child died twenty-five days after birth.)

CASE 2.—I will now give you the notes of a very interesting case of a child which I saw some years ago. When born it was noticed to be of a yellow hue, and this has gradually got more marked. The urine was jaundiced, and the mother said "there was something wrong with the way it passed its water." The motions were always white. The child was bottle fed and had not thriven, and within the last two weeks before my visit it had passed blood-stained mucus by the bowel. It was an only child, and there was no specific history. There had never been any bleeding from the umbilicus. The child when I saw it was small, more like a month than a three months' baby, emaciated, and deeply jaundiced. There was no enlargement of the liver to be detected, nor of the hæmorrhoidal veins. The foreskin was retracted. No urethra was to be seen in the glans or body of the penis, but on its under surface, close to the scrotum, there were two small apertures, one on each side of the middle line. On attempting to pass a filiform bougie into one of these the child voided a quantity of deep saffron-hued urine. There were no spots on the body or sores around the anus, and the child did not snuffle. The umbilicus was natural looking. The child died in two days after I saw it. Now although most unfortunately no post-mortem examination was made, I have little doubt that the jaundice in this infant was due to some congenital stricture in the bile-ducts, from the following facts—(1) the progressively deepening jaundice; (2) the gradual emaciation; (3) the presence of an evident malformation (hypospadias); (4) the intestinal hæmorrhage; (5) the absence of syphilitic history.

CASE 3.—An infant, three weeks old, was seen by me in the out-patient room of this hospital at the beginning of the present session. The woman (its aunt) who brought the baby said its mother had taken ill with a "shivering" three days after the birth of the child, and had been unwell ever since and "unable to give it drink." A week

after birth the child first became yellow, and the colour had got worse, the aunt says, up to the time she came to the hospital. It passed blood per anum, and had been vomiting almost constantly for a week before I saw it. The child, which was very puny, was completely jaundiced. The tongue was dry, the abdomen swollen and painful, temperature 101°, and a mixture of blood and pus welled from the umbilicus. Subsequently I learned that the mother had been ill with puerperal fever, and at a later period I admitted her into my ward at the Royal Hospital, where some of you saw her, with pelvic cellulitis. The child died ten days after it was first brought to the hospital. In this case the jaundice was due to umbilical phlebitis, caused by the same poison, probably, as that which infected the mother.

Now, gentlemen, these three cases are, as I have said, types of the conditions which I have met with as causing fatal jaundice in infants. 1. Syphilitic growths and inflammation. 2. Malformation of the bile-ducts. 3. Umbilical phlebitis. In reference to the second type, it is a curious but well-observed fact that this condition of matters (as pointed out long ago by Dr. Cheyne) is liable to appear in successive children of the same family, an important factor in diagnosis. I am aware of a case where three successive children in one family have died of jaundice caused by malformation of the ducts. Further, bleeding from the umbilicus sometimes is noticed in these cases; and you will remember, I hope, that this umbilical hæmorrhage is of bad prognostic import, as when it occurs the fatality is more rapid. I show you here a chromo-lithograph of a liver from a case of congenital malformation of the ducts. You see it is of a deep olive-green colour, and is in a cirrhotic condition. It is probable that the cirrhosis is secondary to the obliteration of the ducts, as Dr. Wickham Legg has shown that tying the bile-ducts of an animal will in time give rise to a somewhat similar condition of the liver. Dr. Legg thinks that this cirrhotic condition prevents the blood circulating through the liver, and in consequence it passes along the line of least resistance, from the left portal vein to the ductus venosus, and thence to the umbilicus, where the imperfectly healed vessels of the umbilicus yield to the increased arterial pressure, and hence oozing of blood takes place.

Let me say a word in conclusion as to treatment. In the simple form of true jaundice in infants you will see that the bowels are kept regular, and a mixture of a little soda and taraxacum juice will generally bring matters right. In malformation of the bile-ducts no treatment is of any use, while in those cases in which there is a specific history small doses of grey powder should be tried, and the parents should be brought under a mercurial course, so that if there be any more children the virulence of the syphilitic poison may be destroyed or lessened. The prevention of umbilical phlebitis is best done by the employment of antiseptics in midwifery, this form of infantile jaundice being unknown in those lying-in hospitals where rigid antiseptic midwifery is practised.

ON RELIEVING TYMPANITES BY PUNCTURE OF THE ABDOMEN.

BY JOHN W. OGLE, M.D. OXON., F.R.C.P.,
CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL.

(*Continued from page 59.*)

IN 1869, Dr. Braxton Hicks recorded four cases, in the Transactions of the Obstetrical Society,[1] of puncture of the abdomen for flatulent distension; and he alludes to the discussion of the question which had lately taken place in Paris when this treatment was commended, twenty cases, he observes, of the procedure having been included in the paper read. (I have not as yet been able to find any further account of this discussion.) Dr. Hicks says he thinks there is not much risk of extravasation into the peritoneal cavity, as if the smallest exploring trocar be used the tissues of the bowels are rather separated than cut, so that the opening is closed as soon as the instrument is withdrawn. He alludes to extreme tympany as one of the dangers of peritonitis, as pressure of the gas on the sympathetic and the tension of the tissues they supply must add to the collapse and vomiting.

[1] See pp. 47-53.

In 1869, also appeared a case, in the *British Medical Journal* of Aug. 20th, described by Dr. Davey (then of Bristol), of tubercular peritonitis in a child for whom paracentesis was performed by Mr. Salmon of Thornbury, for relief of painful distension by flatus. Large quantities of fetid gas were let out, with great ease to the patient, and this gas continued from time to time to pass off until the death of the child ten days afterwards. It was found, after death, that ulcerative communications existed between the bowel and the peritoneal cavity. Dr. Davey quotes from the *Medical Press and Circular* of April 7th, 1869, two cases in which Dr. Fonssagrives of Toulouse[2] had lately punctured the abdomen several times with marked success, when the patients were in extreme peril from tympanites.[3] He also states that he was informed by Mr. N. Leigh, veterinary surgeon at Bristol, that he had often performed this operation with a trocar or pocket-knife, chiefly on cows, more rarely on horses, and with good results.

In 1869, Dr. Clifford Allbutt of Leeds recorded in the *Practitioner*[4] the case of a man with pneumonia attended by faecal obstruction and most painful and extensive tympanites with hiccough, in which, after the unsuccessful adoption of other remedies, he had the abdomen punctured by Mr. T. P. Teale, who plunged a No. 1 exploring trocar into the distended transverse colon, "by which," he says, "a large quantity of highly offensive air was let out, and then again into the descending colon, with the same result. The abdomen became quite soft, the greatest relief followed, and the patient soon sank into sleep." Shortly afterwards the bowels recovered their activity. The patient sank from the pneumonia. Post-mortem examination showed no trace of peritonitis, nor "had air entered into the peritoneal cavity." No traces of the punctures which had been made could be discovered, except on the surface of the bowel. After dilating on the good effects of such a painless operation giving great and ready relief by emptying the bowel and allowing it to contract upon, and expel, accumulated faeces, Dr. Allbutt remarked that if the medical attendant, on an emergency, has not a fine trocar at hand he may use the needle of his morphia syringe.

In the same year (1869) Mr. Thomas Smith communicated to the Clinical Society[5] the particulars of a case of ruptured intestine, in which the bowel was punctured for relief of distension by flatus. This was done by a fine trocar through the linea alba, half-way between the pubes and umbilicus. "The effect of the puncture was immediate, and the relief to the boy's suffering very great. A large quantity of offensive flatus escaped, the vomiting was less urgent, and he soon afterwards fell asleep. Three hours after the puncture the bowels acted freely, not having before been moved since the accident, seven days previously." Mr. T. Smith quotes a case, from the *Bulletin Gén. de Thérapeutique* for 1867, of obstruction of the bowels, in which, as a last resource, the small intestine was punctured with a fine trocar. A large quantity of gas escaped, and on the same day the bowels acted twice. Fifteen days afterwards, and again later on the puncture was repeated, and on each occasion with the same good result. He also quotes M. Laforgue of Toulouse, who had employed puncture for tympanites in two cases.[6] In one case the puncture was repeated six successive times with great advantage.

In 1870, Dr. H. Wathen, then of Fishguard (now of Clifton), communicated a case to the *Practitioner*,[7] in which a woman with acute peritonitis, accompanied by distressful tympanites, had the puncture performed. A No. 1 trocar was plunged, firstly into the transverse, then into the descending, and lastly into the ascending colon. Relief was at once afforded. The patient, however, sank the next morning.

In the following year (1871) Sir Risdon Bennett (then Dr. Bennett) communicated to the *Practitioner* of Feb. 1871 a short paper on Mechanical Means of Relief in Certain Cases of Inflammatory Effusions, founded on a highly interesting case of peritonitis, which he had seen at Christiania, wherein large quantities of inflammatory products were withdrawn from the abdomen by trocar, and a drainage tube was long worn,[8] and in which also the colon had been punctured for tympanites, apparently, in the patient's view, preserving

[2] See Gibson. [3] Quoted from L'Union Médicale.

[8] The natural evacuation of purulent fluid through the umbilicus in cases of peritonitis (analogous to the process which sometimes occurs in pleurisy) has been several times observed. Such cases are mentioned by Dr. West in his Lectures on the Diseases of Infancy and Childhood. (Third edition, pp. 88 and 506.)

Digitized by Google

life by relieving the accumulation of flatus. Dr. Bennett, in addition to very valuable suggestive remarks on the case, showed that he was quite in favour of puncturing for excessive tympanites, and believed that great advantages were likely to be derived from its practice, though it was "not devoid of danger."

In 1871, Dr. Wathen communicated a paper to the *British Medical Journal* (Oct. 21st), in which he gathered together some of the English cases of which I have given an abstract, and registers another—a case of dysentery in the practice of Mr. Thomas—wherein puncture of the ascending and transverse colon was performed with the best results. Dr. Wathen alludes to the puncturing of cattle for tympanites, as used by graziers, and concludes with the following remarks: "When I picture to myself the immense distress and suffering present in an intensely tympanitic patient, whatever may be its cause, and then recall to mind the ease and quiet, if not anything more, which we are enabled to afford our patient by what I am bound to describe as a simple, harmless, and painless operation, I feel drawn to the conclusion that it is a proceeding not only justifiable, but urgently demanded at our hands." In a letter which I received in April last from Dr. Wathen, he says that he has not had further occasion to puncture the abdomen for tympanites; but that he had been called upon, along with Dr. Howard of Newport, Pembrokeshire, to puncture a large hernia several times with the view of reducing its size." Subsequent to Dr. Wathen's communication, Dr. Saunders, resident physician at the Devon Asylum, sent a memorandum to the *British Medical Journal*,[10] in which he gives an interesting *résumé* of what had been advanced by authorities in the last century regarding the proceeding in question. To this communication I have elsewhere alluded.

In the same year (1871) the same journal (Nov. 4th) contained the details of a case, related by Mr. Brown of Ealing, of a boy suffering from tubercular peritonitis. Collapse came on in spite of remedies; but entire recovery followed puncture of the abdomen, which was performed on two occasions by means of a small trocar, liberating large quantities of fetid air, followed by a drop or two of pus.

In the year 1873 (February), Dr. H. C. Cameron read before the Medico-Chirurgical Society of Glasgow[11] a paper on what he termed "Colo-puncture." In this he described the case of a man who, after an operation on the leg, had rigors, and pain and swelling of the abdomen. As the abdominal distension became extreme, after fruitless resort to other means, puncture of the colon was performed; and this had to be done on eight separate days,[12] with the greatest relief and at the urgent desire of the patient, who got well, no increase of the peritonitis taking place. When the over-distension of the bowel arises from mechanical obstruction, Dr. Cameron thinks that the operation has, very often, many advantages over the use of the long tube passed into the bowel. It is, if properly done, he says, not more risky, inasmuch as some danger, and often difficulty and great discomfort, attends the use of the tube, and its success is by no means uniform. The undesirability of repeating the passing of the rectal tube is great. Dr. Cameron closes his paper by indicating the precautions necessary to be taken in performing these operations—viz., that the cannula should fit very accurately around the collar of the trocar, that the trocar be of sufficient length—that is, three or four inches long—that any amount of pressure on the abdomen should be avoided (for fear of squeezing out fluid from the bowel), that the puncture should always be at the most prominent part of the abdomen as the patient is lying.[13] In the discussion upon Dr. Cameron's paper, Dr. Lyons said that, in a case of his, fæcal matter was found, on post-mortem examination, in the peritoneal cavity, but that this might have escaped after death. Dr. Buchanan had, since 1819, seen half a dozen cases of puncture for tympanites. He advocated the plan of puncturing the bowel with an aneurysmal needle threaded with wire, withdrawing the needle, and leaving the wire as a loop inside the bowel, which could be moved daily, thus allowing escape of the gas and avoiding the necessity of repeated puncture. Dr. E Watson doubted the advisability of puncturing the abdomen in cases of inflammation. At a later date,[14] Dr. Cameron suggested colo-puncture in a case of intestinal obstruction arising either from paralysis of the walls of the bowel or from bands of lymph (of nine months' standing), under the care of Dr. McGown, which was completely successful. In this case liquid fæces, which were escaping through the trocar, were washed back by tepid water. Three hours after the operation the bowels had copious relief, and the patient recovered quickly. In the discussion at the Glasgow Medico-Chirurgical Society upon this case, Dr. Glaisher and Dr. J. Coats said they had performed the operation. In a private letter Dr. Cameron informs me that he has performed the operation in many cases of over-distension by flatus. He considers that, when done with proper precautions, it is quite devoid of danger, and in many cases is very useful. He remarks that "gas seems occasionally to exist in compartments in the intestine, even in cases in which the entire abdomen appears greatly and uniformly distended. "I suppose," he says, "sharp bends and turns of the gut may thus subdivide the gas into separate collections. At all events, it often happens that, immediately on the withdrawal of the trocars, gas whistles through the cannula with as much force as might blow out a taper, but in a minute or two stops, even although much tightness and distension continue. In such cases I do not hesitate to puncture in a second spot." He tells me of the case of a lady five months pregnant having obstruction of the bowels, which were enormously distended, no evacuations having taken place for five days, which he lately punctured in two places. He observes that "only a small quantity of gas escaped, still she soon began to pass flatus 'per anum'; a movement of the bowels followed, and she recovered. At the time of the operation she was within a very measurable distance of death." In another case, obstruction of the bowels following fracture of the leg, Dr. Cameron punctured on two successive days, and, as a result, flatus began to be passed per rectum; the bowels were moved, and the man got well of the obstruction. He died of pneumonia later on, and at the post-mortem examination it was found that there had been intussusception of the bowel.

In 1876 an interesting case was published in THE LANCET[15] by Dr. Finch of the Leicester Borough Asylum, showing the use of the aspirator in relief of excessive tympanites attended by vomiting, constipation, and abdominal pain, which seriously embarrassed the heart's action. The instrument was introduced half way between the pubes and umbilicus, and a large amount of flatus withdrawn, with immediate good result. Two days later the patient was worse as to vomiting, &c., and she appeared to be moribund. As a last resource the aspirator needle was again used, being passed into the cæcum, when a large quantity of gas and a little feculent fluid escaped. Action of the bowels followed, and there was no further use for the puncturing. No inflammatory action arose, and the patient recovered.

In 1877, Dr. Godlee brought three cases before the Clinical Society of London,[16] in which gas was contained in the peritoneal cavity, without any perforation of the bowel existing. These were adduced as drawing attention to an incident which may happen in the course of the operation of colotomy. In one case there was ulceration of the colon, in the second one colotomy was performed, but the amount of gas which was met with in the peritoneal cavity for a time prevented

[illegible] With regard to the procedure of getting rid of flatus in strangulated hernia, here and elsewhere alluded to, Dr. Cameron (referred to later on) offers an objection—viz., that "if it do not succeed, and an operation becomes necessary, the free handling of recently punctured gut might possibly lead to unpleasant consequences." On this point, also, I will quote Mr. Bryant, who, in a Clinical Lecture on Intestinal Obstruction (see Medical Times and Gazette, April 20th, 1872, p. 455), stated that his objection is much against puncturing the bowel in cases of hernia, when distended with flatus, owing to the risk of escape of fæces or fluid, though he had resorted to it in two cases of ileus with immense advantage. He mentioned that at Guy's Hospital the operation had been done more frequently than at any other institution; and that Mr. Stocker, "who had had more clinical experience than almost anyone in London," has always spoken favour of it. He quoted the case of an old man with strangulated hernia, in which the operation of pricking the bowel four or five times successfully performed. Mr. Dent, of St. George's Hospital, says that he has "a strong disbelief in the utility of puncturing the bowel in tympanites," thinks that in strangulated (external) hernia the distension appears to constitute the chief difficulty of reduction; "puncture does not enable the gut to be reduced more than a slight division of the stricture, and therefore inflicts a needless wound." The late Mr. Tatum, a former colleague of mine at St. George's Hospital, was in the habit of puncturing the intestines when, owing to the difficulty of reducing the strangulated hernia, they could not be returned. [illegible] Medical Journal, May 1878, p. 989. [illegible] not obtained, as the instrument did not [illegible] to one possible source of failure in the opera-

[10] Nov. 18th, 1871.

[11] To meet the risk from fluid being squeezed out of the bowel, it is suggested that a small syringe should be used with warm water to wash back any fluid fæces which may exude through the trocar.

the colon being found, as the peritoneum was protruded by the gas in the cavity. In the third case (as in the second) colotomy was performed by Mr. Heath.

In 1879, Mr. G. Brown brought before the same Society[17] a case of typhoid fever, in which an accumulation of odourless gas took place in the peritoneal cavity, without any perforation of bowel occurring. Puncture, with absolute relief to urgent symptoms, was resorted to; the pulse fell at once from 50 to 36, and the heart regained its natural position. This change enabled a greatly distended condition of the urinary bladder to be recognised. Mr. Brown's account contains some interesting speculations as to the origin of the gas formed within the peritoneal sac.

In 1879, Dr. Broadbent described in the *British Medical Journal* (Sept. 27th) a case of intestinal obstruction, owing to the pressure of a pelvic tumour, successfully treated by repeated puncture of the small intestine by means of a long aspirator needle. He mentions some necessary precautions to be observed in performing the operation.

In 1884, Dr. Hunter brought before the Obstetrical Society of New York[18] a case in which, following a subsequent peritonitis, tympanites was so urgent that the patient appeared moribund. The use of the long rectal tube proved insufficient for relief, and the abdomen was punctured by a long hypodermic needle, when gas escaped, and continued to do so for half an hour. The patient recovered. The gas was not offensive, and had accumulated in the peritoneal cavity. In the discussion, Dr. Nicoll, Dr. Murray, and Dr. Polk related cases showing the good results of the operation. In a subsequent meeting the latter gentleman quoted another case in which death was averted by the operation.

Quite recently Mr. W. Furner brought before the Brighton and Sussex Medico-Chirurgical Society[19] two cases of abdominal puncture for flatulent distension. In both instances fæcal escape took place; and in one case it was found, after death, that it was the small intestine which had been pierced.

(To be concluded.)

ON INHALATION AND THE LACK OF PRECISION IN THE METHOD OF USING IT;

WITH A DESCRIPTION OF DR. ISOARD'S "SULFHYDROMÈTRE."

BY W. SINCLAIR THOMSON, M.D., F.R.C.S. EDIN.,
LATE CONSULTING SURGEON, PETERBOROUGH GENERAL HOSPITAL, AND MEDICAL OFFICER OF HEALTH.

CONTINUING my tour of inspection of continental spas, it was my good fortune to visit Allevard in the lovely highlands of Savoy last September, and in the hope that I may be able in some slight degree to contribute towards our knowledge of "healing springs," I submit the result of notes taken at Allevard, together with translations from those of Dr. Isoard.

1. *On inhalation and on the lack of precision in the method of using it.*—The inhalation of the gaseous constituents disengaged by sulphurous mineral waters has gained in the therapeutic treatment of diseases of the respiratory passages a rank which is now no longer disputed. Clinical observations have proved its value. The superiority of this method is the result of the double action that it allows the sulphurous vapour to exercise on the organ. The first, which is entirely local, is due, as is now well known, to contact with the very sensitive mucous membrane of the bronchi; the second, which is general, resembles that of water taken in drinking, and is the result of its absorption by the lung and subsequent diffusion over the whole system. But even if no doubt be thrown on the power of this treatment, yet we must acknowledge that it is applied under very defective conditions. Neither doctor nor patient has any means of determining the intensity of the treatment pursued. It is graduated, indeed, simply by calculation of the time of remaining in the inhalation rooms. Yet nothing could be more uncertain than this determination. Numerous experiments made with test papers, either entrusted to patients or placed in different parts of the room, or by a standard sulphydrometer for water, have shown that there are considerable differences in the quantity of mineral constituents diffused in the atmosphere.

Dr. Isoard found in two experiments a degree of sulphuration four times greater in the one than in the other; and yet at Allevard, where the method was first used, nothing was neglected to ensure the inhalation all its power; the arrangement of the rooms leaves nothing to be desired; the water which feeds them is subjected to a system of spraying and evaporation, which releases from it nearly all the gas it holds in suspension. The reason of this variation lies in the fact that the chemical composition of the atmosphere can be altered by causes which an irreproachable arrangement could not foresee. I will confine myself to quoting the most evident: (1) certain barometric conditions favour or impede the disengagement of the gas contained in the waters; (2) the proportion of sulphurous vapour mixed with the air of the room varies according to the number of patients in the room and the time which has elapsed since the beginning of its action.

2. *Consequences of irregularity of treatment.*—The variation in the degree of impregnation of the air intended for inhalation being recognised and its principal causes pointed out, it is necessary to indicate the inconveniences, even dangers, to which those who undergo it are thereby exposed. All the gases given off by sulphurous waters have not the same therapeutic importance nor the same harmlessness. Carbonic acid and nitrogen, for example, only increase the proportion of these same elements which enter into the composition of ordinary air; and even if their action on the animal economy can sometimes be profitably employed, yet it may be said that it is not sufficiently powerful to necessitate a rigorous system of dosing. But the same remarks do not hold good of sulphuretted hydrogen, a very powerful gas, to which the inhalation owes its curative properties, and which standardises the therapeutic richness of all sulphurous waters, since therein lies the resultant of all the decompositions of the various substances which are dissolved in the waters. The absorption of this gas by the pulmonary passages is preceded by an energetic action on the tissues with which it comes in contact before being assimilated into the blood. This local action shows one of the most remarkable therapeutic properties of the gas—namely, that which is due to the slight excitatory movement to which it gives rise, and whose resolutive action on lesions of the respiratory organs is nowadays well known and established. But this excitatory or inflammatory movement requires the greatest vigilance. The limit may easily be passed. Congestion, even hæmorrhage, may result from the unseasonable or irregular administration of a remedy otherwise very valuable. There is therefore an absolute necessity of giving this mode of treatment the degree of precision which it lacks, a defect which is very often the only reason for hesitating to try it. The number and duration of the sittings give altogether insufficient indications of the quantity of sulphuretted hydrogen absorbed. Some patients believe they can be guided by the intensity of the characteristic odour liberated by the water. This proceeding gives rise to the same errors. The odour of the water does not give a measure of its degree of sulphuration. It would be more logical to take as a guide the observed physiological effects. But everybody cannot gauge them to the same degree, and their manifestations are not absolutely constant. Yet an analysis of the air of a hall, every time it is to be used, is out of the question. That would necessitate the construction of a small inhalation room for every patient. What is absolutely indispensable is not an analysis giving the exact quantity of sulphuretted hydrogen diffused in the atmosphere, but a method capable of indicating in a visible manner, evident to everybody, the variation in the degree of sulphuration of the atmosphere intended for inhalation; in fact, a kind of registering apparatus by means of which every patient can follow the graduation of his treatment.

3. *Mode of using Dr. Isoard's sulphydrometer.*—Dr. Isoard says: "The process which I propose to employ seems to me to fulfil all the conditions," which we have discussed above. "It consists simply of an application of the means I have used to find out the irregularities I have mentioned. The test papers, impregnated with a solution of a salt of lead, take in contact with the sulphuretted hydrogen a tint which is the more intense the longer the exposure is continued, as the degree of sulphuration of the atmosphere is high. It seemed to me natural to take the shades which correspond to the time usually given to the sittings, and to exactly reproduce them in unalterable colours, forming a gradation of tints through all of which the test papers have to pass, and to give the gradation thus obtained a form easy of com-

[17] Transactions, vol. xii., p. 235. [18] Ibid., June 3rd.
[19] British Medical Journal, May 5th, 1887.

Digitized by Google

parison. Moreover, the scale of shades has been determined in a room set apart at my disposal for this special purpose. The quantity of the water was carefully ascertained and also the amount of sulphuretted hydrogen it contained. No patient was allowed in the room during the experiment. The tints, then, have been obtained in an inhalation room acting under the most regular conditions. They have been arranged on a card pierced with two longitudinal slits to admit of the application of the test-paper opposite the shade one wishes to obtain. The greatest care has been given to the reproduction of these tints, to the choice of paper, and the preparation of the solution with which it is impregnated. The indications which this table can furnish will have a character of precision, which a measurement of the time passed in the room cannot give.

"Of course it must not be required of a process like this to furnish with the exactitude of a laboratory instrument the quantity of sulphuretted hydrogen in the air in milligrammes—that is, moreover, not necessary. But this apparatus, placed in the room beside the patient, or affixed to his clothing, undergoing simultaneously with him the action of the air he breathes, informs him whether he ought to prolong or shorten his stay, and gives him a protection against the disappointment of an illusory treatment and the unpleasant surprises of one too strong. The mode of using it is so simple that everyone can do it. The shade of the test paper must coincide with the one which has been assigned to the patient on the graduated table. This comparison is much facilitated by applying to the apparatus a narrow, thickish piece of paper, pierced with an opening, across which the juxtaposed tints are compared. The sulphuretted hydrogen acts with most intensity on the edges of the paper. It is the middle portion that should be compared with the table. To regulate the intensity of the treatment according to the degree of sensitiveness of the paper, it suffices to know that tint No. 1 corresponds to the shortest sitting usually prescribed (about three minutes).

"All that I have said refers to *cold* inhalation, the one usually practised and whose use requires the most care. It is so called because the rooms thus used are supplied exclusively with cold mineral water, and thus have a temperature differing but little from that of the open air. But there is another kind of inhalation, the *tepid* or *temperate* inhalation. It differs from the first in that the rooms assigned to it, and the mineral waters also, receive a jet of steam from ordinary water, which, while partially condensing, raises the temperature of the room to about 28° C. or 30° C. (= 82° F.—86° F.). This condensation gives rise to a light spray formed of very minute drops, whose part an ingenious theory has well explained. These minute drops dissolve the gas given off by the mineral water on account of the temperature and pressure forming a spray of chemicalised water in so fine a state of division as no pulverisation could produce, and thus penetrates, with the sulphurous element, into the finest ramifications of the bronchi.

"It is evident that this treatment, which has its special indications, is nothing but a simple application of thermal hydro-therapeutics. One thing which distinguishes the tepid inhalation is the fact that the sulphuretted hydrogen coming by this process in contact with the mucous membrane of the bronchi has a more feeble local action on it. Everyday experience proves, indeed, that a length of time can be given to the sittings for tepid inhalation which would be dangerous for cold inhalation. The sulphydrometer, since it does nothing but faithfully show the variations of the degree of sulphuration of the atmosphere, can be used in all the rooms assigned to the two kinds of inhalation. In the tepid inhalation rooms, however, the shade corresponding to the shortest, which is taken as the starting point, should be one degree higher than in the cold inhalation rooms, on account of the greater tolerance of the action of the gas, which I have mentioned, and the greater sensitiveness of the test papers in a humid atmosphere. The name of sulphydrometer, given to an apparatus which does not accurately determine the dose of sulphuretted hydrogen, may seem pretentious to some; to me, however, it seems justified. Nevertheless, I should be glad if only its title is criticised, if its utility is recognised, and if a kindly reception is accorded to my modest efforts towards a therapeutic [illegible] which has stood its tests, but whose results will become certain when scientific and precise methods of [illegible] are employed for its application."

The [illegible] at Allevard are of the same character as those of [illegible], being at a higher elevation the air is more bracing. They are beneficial in rheumatic and gouty ailments, sciatica; particularly beneficial for throat affections and delicate children. The majority of persons who resort to Allevard labour under affections of the organs of respiration. I have had demonstrated to me the great benefit derived from the Allevard treatment in lymphatic tubercular subjects, cases of chronic laryngitis, asthma, and pulmonary or laryngeal affections. Dr. Nièpce (the medical inspector of the baths) speaks highly of Allevard as a health-resort for children, especially if suffering from chronic pharyngitis and enlargement of the tonsils. Allevard is not two hours further than the now fashionable Aix-les-Bains, on the same line of rail, and we get a fresher air, away from excitement, excessive luxury, and their accompanying expenditure. The fame of mineral waters is a thing of slow growth, and of no great permanence when gained; many highly esteemed by the last generation are now wholly disused. I feel confident that the more Allevard and the medical treatment there are known, the higher it will rise in public esteem.

Ladbroke-grove, W.

TRACHEOTOMY AND INFLATION IN THE TREATMENT OF A STILLBORN CHILD.

BY CHAS. SCOTT WATSON, M.D.

THE treatment of stillborn children is so unsatisfactory in some cases that I make no apology for publishing the following unsuccessful case, in which the ordinary treatment was supplemented by tracheotomy and inflation of the lungs.

Mrs. H——, aged twenty-nine, was confined of her second child (a boy) on Jan. 5th, 1887. Her first child was born two years and a half ago, after a severe instrumental labour, and lived four days. Concerning the confinement, in which I attended her, the following points may be mentioned:—I was called to her at 5 P.M. on the 4th, she had been in labour since 2 P.M., the os was the size of a shilling, the membranes intact, and the vertex presenting in the first position. At 7 P.M. the os was fully dilated and the membranes were ruptured. The head entered and stuck in the brim of the pelvis, and at 2 A.M. on the 5th forceps were put on and delivery easily effected. On the delivery of the head the mouth and throat were cleared of mucus, and the child made one or two ineffectual attempts at inspiration. When delivery was completed, which occurred without any unusual delay, the child was pale and flaccid, but its heart was beating strongly, at the rate of about 60 a minute, and at intervals of a quarter of a minute or so it made a single strong inspiratory effort, in which the chest walls were sucked violently inwards, but no air entered the lungs. The usual means of resuscitation—slapping, sprinkling with cold water, artificial respiration, &c.—were used without result. I then made several attempts to pass a catheter into the larynx by the mouth, but failed, and last of all tried insufflation from mouth to mouth with pressure backwards on the trachea, without producing any good effect. By this time the child was cold, and evidently at the point of death. The inspiratory efforts, always ineffectual, still occurred, but so feebly and at such long intervals that each appeared likely to be the last, and the heart was scarcely to be felt beating. As it seemed that nothing was to be gained by simple persistence in the foregoing treatment, and as the symptoms pointed to some obstruction to the entrance of air into the lungs, tracheotomy was rapidly performed. There was no bleeding. A No. 7 male gum-elastic catheter was then passed into the trachea and air blown down it. During these insufflations it was found necessary to hold the child's mouth and nose, and also the edges of the wound, tightly round the catheter, to prevent air escaping at these openings; but in spite of all the nurse and I could do some air always did escape. Expiration was produced by pressure on the chest. As each of these acts caused a bubbling noise in the air passages, the action of the catheter was reversed, and about a drachm of mucus and meconium was sucked up into its tube and so got rid of. The spontaneous inspirations still continued at long intervals, but now of course drew air into the chest, and the heart's action soon began to improve. After this artificial respiration had been persevered in for about half an hour, each spontaneous deep respiration was followed by five or six rapid shallow ones, and in about an hour after its birth the child was breathing freely, moving its limbs, and crying when the wound was

Digitized by Google

closed. During the day it did well, taking some brandy-and-water, and breathing almost constantly through the mouth and nose. It was only in an occasional very deep respiration that the edges of the wound in the trachea were forced and a little air escaped. At 8 P.M. I put in three stitches, nearly closing the skin wound, and at the same time showed the nurse how to remove them if any dyspnœa should occur. At 1 A.M. (6th) the child coughed and struggled a little, and although the wound was opened the breathing became weaker, and ceased about half an hour later.

Permission was obtained for examination of the lungs and air-passages only. The lungs, trachea, and larynx were removed together. There was a little emphysema of the loose cellular tissue behind the œsophagus at the level of the larynx. The larynx was clear. The operation wound divided the crico-thyroid membrane, the cricoid cartilage, and the two upper rings of the trachea. The upper and middle lobes of the right lung were fully expanded, the lower lobe only partially. In the left lung a little patch at the apex and a strip along the free margin of the upper lobe alone contained air; the rest, including the whole lower lobe, was in its fœtal condition. On the posterior surface of both lower lobes there were a few subpleural ecchymoses. When the whole preparation was put into water the right lung floated, the left sank. On attempting to inflate the lungs with a Higginson's syringe, it was found impossible to do more than slightly expand the parts that already contained air till a small opening accidentally made in the left bronchus was closed, when they inflated readily and fully. The nozzle of the syringe just fitted the trachea.

I think the case encouraging because the atelectasis, which appears to have been the cause of death, is, I believe, to be accounted for by the imperfect apparatus I employed. A No. 7 catheter which does not fit the trachea, and therefore makes it necessary not only that the edges of the wound should be held tightly round it, but also that the mouth and nose should be kept closed against the escape of air, is not a good instrument for artificial respiration. The effect of such an escape was shown in the failure of the attempt to inflate the lungs post mortem until the opening in the bronchus was closed. During life I was never able to keep the mouth, nose, and wound air-tight, and therefore think that this escape of air during inflation was the main cause of the poor expansion of the lungs. In another case I should guard against it by using a nozzle that would plug into the trachea—e.g., that of a Higginson's syringe. This, with the adjacent piece of tubing, might be detached from the ball and inflation made by blowing down it.

Tufnell-park, N.

BILATERAL PARALYSIS OF THE DILATOR MUSCLES OF THE GLOTTIS, WITH SUBSEQUENT PARESIS OF THE CONSTRICTORS.

BY PERCY KIDD, M.D., F.R.C.P.,
ASSISTANT PHYSICIAN AND PATHOLOGIST TO THE BROMPTON HOSPITAL.

SINCE the time when paralysis of the crico-arytenoidei postici muscles was first actually observed with the laryngoscope by Professor Gerhardt in 1863,[1] this condition has attracted much attention. Subsequently, cases were recorded by Morell Mackenzie, Riegel, Penzoldt, Semon, Rosenbach, Paul Koch, and others, and the list continues to swell steadily. Nevertheless, until recently the impression has prevailed that this form of laryngeal palsy is decidedly uncommon. Within the last few years a very different opinion has been expressed, and evidence is accumulating in favour of the view that the dilator muscles of the glottis, or abductors, are specially liable to paralysis.

It may be well here to give a short abstract of the work done on this subject in recent times, as most of the papers are only to be found in German periodicals.

Dr. Morell Mackenzie, in his work on "Diseases of the Throat and Nose," published in 1880, speaking of laryngeal affections due to disease of the brain, says: "The laryngeal symptoms vary greatly; in some cases the nucleus of one recurrent nerve is completely destroyed, and we have loss of power of all the muscles acting on one vocal cord, whilst in others the nuclei of the adductor or abductor filaments may be alone involved; hence sometimes there is merely hoarseness or loss of voice, whilst in others there is great stridor in breathing."[2] Again, we read, a few pages further on: "Experience has shown that the abductor filaments are more often pressed on than those going to the adductors. The reason of this is not at all obvious; it may be that the abductor filaments are more superficially situated than the adductors, or it may be that the adductors receive an increment of nerve force from the superior laryngeal nerve; the fact that the arytenoideus or central adductor certainly receives some filaments from this nerve supports the latter view. But whatever the cause may be, it is undoubtedly true that pressure on the recurrent nerve, if not complete, is more apt to affect the abductor than the adductor filaments."[3] The second quotation seems to show that Dr. Mackenzie had modified the opinion expressed previously.

Dr. Ottomar Rosenbach and Dr. Felix Semon made still more important contributions to the subject, and arrived at somewhat similar conclusions independently. The former writer drew an analogy between the abductors of the vocal cords and the abductor muscles of the body generally, and maintained that just as the abductors are more prone to undergo paralysis from nervous affections than the adductors or flexors, so the dilator muscles of the glottis are more liable to become palsied than the constrictors or adductors, when pressure is exerted on the recurrent laryngeal nerves. Rosenbach suggested that the movement of the vocal cord towards the middle line, which sometimes occurs in cases of bilateral abductor paralysis, on deep inspiration, is the result of a perverse or paradoxical innervation of the constrictor muscles, and is not due, as some have said, to atmospheric pressure. These views were founded on a case of carcinoma of the œsophagus, in which both recurrent nerves were involved, without any implication of the larynx itself. Bilateral abductor paralysis was followed by complete paralysis of both vocal cords.

Dr. Semon went still further, and argued for a specific vulnerability of the abductor nerve fibres, whatever the disease and wherever it might be situated, from the origin of the motor nerves of the larynx in the medulla oblongata down to their peripheral termination. According to this view, whether the disease be of a degenerative nature affecting the medulla oblongata—e.g., tabes dorsalis,—a new growth or aneurysm involving the nervous filaments in their course to the laryngeal muscles, the result is the same. In the early stages of interference with the motor nervous mechanism, the dilator muscles are the first to become paralysed. If the lesion be progressive, the adductor muscles subsequently become involved, and the final result is complete paralysis of the adductors as well as the dilators. This generalisation, based upon a considerable number of cases of central as well as peripheral disease, was first enunciated by Dr. Semon in a foot-note to his German translation of Dr. Mackenzie's work, published in June, 1880, though the remarks were written in 1879. It is true that Rosenbach brought forward his theory in November, 1879, but it was not till January, 1880,[4] that it appeared in print. It is unnecessary here to enter into the question of priority, which Rosenbach has argued recently[5] with some warmth, for his statements are sufficiently answered by a previous paper of Dr. Semon's.[6] There seems to be no reason to doubt that these authors had arrived at their conclusions quite independently. Objections have been taken to these views by Schnitzler, Solis-Cohen, and others, but the cases which have been adduced to support these objections are not free from considerable doubt, as will be seen from a perusal of Dr. Semon's paper last referred to. A far more serious attack on Rosenbach and Semon's doctrine was made by Dr. H. Krause of Berlin.[7] This author, on the strength of an experimental study of the results of irritation of the laryngeal nerves in animals, strove to show that most of the cases hitherto described as paralysis of the dilators of the glottis were really due to a primary neuropathic contracture of the constrictors or adductors. Krause's experiments may be divided into two-

groups. In the first electrical stimulation was employed, whereas in the second class he subjected the nerves to a process of gentle but prolonged pressure. Electrical stimulation (*a*) of the peripheral end of one recurrent nerve was followed by closure of the glottis, the corresponding vocal cord coming over the middle line to meet its fellow, which remained motionless, although a slight simultaneous inward movement of its arytenoid cartilage could be observed. This last fact is explained by Krause in the light of Exner's researches, which show that not only is the inter-arytenoideus muscle supplied both by the superior and inferior laryngeal nerves, but that each lateral half of the muscle receives almost as many branches from the nerves on the opposite side as from those on the corresponding side of the body. Krause notes a curious fact at this point—viz., that closure of the glottis ceased on the occurrence of inspiration in spite of the persistence of electrical excitation. (*b*) Irritation of the central end of the superior laryngeal nerve, when its external branch remained intact, gave rise to firm closure of the glottis, and also to sphincter-like narrowing of the aditus laryngis. (*c*) Stimulation of the central end of the vagus was followed by a movement of abduction on the part of the opposite vocal cord.

In the next series of experiments the following method was employed. A catgut violin string, softened in water, was very carefully passed under the nerve on each side without damaging it, and was then tied in a loose loop. A small cork was then gently inserted into the loop so as to press slightly on the nerve. Soon after this operation, vibratory twitchings were noticed when attempts were made at adduction, although the excursions of the cords remained perfect, and the glottis continued to dilate freely and with regularity. Subsequently stridulous breathing developed, but soon passed off; and twenty-four hours after the operation the animal breathed quietly and normally. Notwithstanding this fact, a laryngoscopic examination now showed that the vocal cords were fixed firmly in the middle line, leaving only a minute fissure between their cartilaginous portions posteriorly, as is always the case during closure of the glottis in dogs, the animals operated upon. If, as sometimes happened, the cork slipped out of the loop, the vocal cords as a rule showed no impairment of their excursions in either direction, although the nerve already presented evidences of inflammation. When any restriction of the movement of the cords did occur, opening of the glottis was not more interfered with than closure. If the cork was again inserted, tonic contraction reappeared. The same results were obtained by compression of the peripheral ends of the divided recurrent nerves. Compression of the vagus trunk was followed by fixation of the corresponding cord in the position of quiet inspiration. The condition persisted, and the observations could be repeated for a period of from two to five days, after which time total paralysis of the vocal cords ensued.

At the post-mortem examination the nerves were found in various stages of inflammation. Many of the fibres of the crico-arytenoidei postici showed slight opacity and indistinct striation, whereas the adductor muscles were quite free from any change. During rigor mortis the glottis was seen to be closed, the vocal cords lying close together. Krause considers that the median position of the vocal cords was due to the slight irritation set up by the pressure of the cork, giving rise to a tonic contracture of the adductor muscles. He bases this opinion on several points—e.g., the persistent character of the affection of the glottis, the anatomical evidences of inflammation presented by the nerves, the development of the same affection when the experiment is conducted on the divided nerve, the identity of the effect produced whether electrical stimulation or pressure be employed, and the closed condition of the glottis during rigor mortis. The apparent limitation of the contracture to one group of muscles is explained by the preponderance of the adductors over the dilators, which he thinks is [illegible] proved by the position of the glottis after death. [illegible] the latter part of the article he maintains that the larynx is only required for phonation, and offers a hindrance [illegible] which is only removed by the action of the [illegible] postici. This action represents a reflex [illegible] of continuous stimulation of the vagi. [illegible] of these muscles reaches its maximum [illegible] but does not entirely cease during [illegible] in the degree of abduction accom- [illegible] inspiration being due to the elasticity of the vocal cords. Krause is not satisfied with explaining the results of his own experiments in this way, but endeavours to show that the majority of cases of abductor paralysis recorded by various observers could be more easily explained on the hypothesis of a neuropathic contracture of the adductors.

In an excellent abstract[8] of Krause's paper, Professor B. Fraenkel makes some important criticisms on these views. He points out that a primary neuropathic, as distinguished from a paralytic contracture, is a very rare affection, and has not yet been experimentally produced. A contracture of this kind develops very slowly, whereas in Krause's experiments it is said to have been established within twenty-four hours. Moreover, it is impossible to follow Krause when he attributes the degenerative changes in the postici muscles to the contracture of their antagonists, the adductors, considering that the post-mortem examinations were made at the latest within five days after the operation. The whole argument turns on the preponderance of the adductors, which Krause assumes. The position of the glottis described as constant during rigor mortis, should it be confirmed, is not decisive as to this point. We are told that the closure of the glottis, which results from electrical stimulation of the recurrent nerve, ceases on the occurrence of inspiration, although the stimulation is maintained. How is this to be explained if we assume that even during forcible inspiration the adductors are still predominant?

If, on the other hand, it be granted that during forcible inspiration the preponderance of the adductors is arrested, it is difficult to understand how apposition of the vocal cords can be the result of a contracture. The hypothesis of a contracture merely adds to the mystery of the question. Now, the condition in man recognised as abductor paralysis is no contracture, the vocal cords are lax, not tense, and on phonation they can be seen to be put on the stretch. When phonation ceases they relax in virtue of their elasticity and diverge slightly, but the muscular contraction of the postici required to produce external rotation of the arytenoid cartilages is wanting, and consequently the glottis remains a mere chink. Again, the fact that this affection occurs whether pressure be exerted on the recurrent laryngeal or on the trunk of the vagus, shows that it is unsafe to draw conclusions from Krause's experiments on animals. Lastly, Professor Fraenkel quotes some experiments made by Zederbaum[9] on the results of pressure on nerves, which prove that the application of the clamp is at once followed by loss of reflex excitability of the nerve, though the motor irritability remains. On removing the clamp, the reflex excitability is completely restored. These experiments suggest a clue to the solution of the present difficulty; for if we regard the peculiar stimulus on which the tonus of the crico-arytenoidei postici depends as equivalent to reflex irritability, the immediate effect of pressure on the motor laryngeal nerves would be loss of reflex irritability of the postici, the motor excitability of the vocal cords in other respects being still preserved.

Seifert[10] records three instances of laryngeal paralysis occurring in patients with other signs of lead poisoning, which he attributes to the influence of lead. In one there was paresis of the arytenoideus proprius, in another complete paralysis of one recurrent nerve, and in the third the vocal cords were in the median position, and there was œdematous swelling over the arytenoid cartilages. In the last case he had an opportunity of a post-mortem examination, and found the postici muscles greatly atrophied. No information is given of the condition of the crico-arytenoid articulation. Seifert considers that these cases show that different laryngeal muscles may be picked out by the poison, in opposition to the views expressed by Semon.

An attempt was made by Simanowski[11] to elucidate the question by a careful microscopical comparison of the nerve terminations of the dilator and constrictor muscles of the glottis with those of the red and pale muscles of the extremities in the sense in which a distinction has been drawn by Ranvier and Krause. Simanowski found that the abductors correspond with the red muscles, and the adductors or constrictors with the pale muscles of Krause. The subdivisions of the nerves are shorter, thicker, and more numerous in the pale muscles, longer and more delicate in the red muscles. The motor end plates are very numerous in the former, but scanty in the latter.

In a dissertation published at Leyden,[12] Dr. G. D. Cohen Tervaert raises objections to Krause's views, believing that pressure on motor nerves nearly always causes paralysis, not spasm. He finds as the result of the examination of a large number of dead bodies at the hospital in Leyden that Krause's statements as to the position of the glottis post mortem are incorrect, the glottis being open at its posterior end in every case. He mentions a fact pointed out by Professor MacGillavray, that it is necessary to puncture the trachea or divide it before the thorax is opened, as otherwise the collapse of the lungs forces air through the glottis, and may interfere with the observation. This writer accepts the idea of a paralysis of the abductors, but considers that Semon's explanation is insufficient, considering that no unequivocal case has yet been recorded of paralysis of the postici passing into complete paralysis of the recurrent laryngeal nerve. Attention is directed to the fact that the postici are the only dilators of the glottis as compared with the greater number of muscles that close the glottis. The apparent proclivity of the dilators to disease is to be explained in the light of Exner's observations, which prove that whereas many of the muscles of the larynx are supplied by both superior and inferior laryngeal nerves, the postici are almost entirely innervated by the recurrent branch, and are therefore more liable to suffer when this nerve is diseased than the adductors.

Krause's views were also subjected to a severe criticism by Rosenbach,[13] but the arguments adduced by him are much the same as those of Fraenkel.

At the meeting of the Laryngological Section of the Association of German Naturalists and Medical Men, held at Berlin in September, 1886,[14] the question was reopened by Dr. Semon. In the discussion that followed Krause reasserted his position. Remak maintained that the dispute could only be settled by clinical and pathological experience, not by experiments on animals. A persistent primary contraction of the adductors was only conceivable on the hypothesis of a reflex origin. Moreover, irritation of purely motor nerves gave rise to clonic spasms, not to tonic contracture. Meschede referred to a case of bilateral abductor paralysis he had cured by injections of strychnia, which could hardly be explained on the contracture theory. Dr. Semon, in his reply, pointed out that the idea of a reflex contracture could not be entertained in Krause's experiments, for the same median position of the vocal cords was obtained whether the cork was fastened to the peripheral end of the recurrent nerve or to the undivided nerve. If the fact should be established that a primary neuropathic contracture could be produced under similar conditions in the case of other nerves, he would be convinced, not otherwise. Several other cases have been recorded recently[15] which bear on this point, but I have only mentioned some of the most important contributions to the subject, as it would exceed the scope of the present communication to quote and discuss all the papers lately published.

(To be concluded.)

REMARKS ON THE

ACCIDENTS WHICH NOT INFREQUENTLY OCCUR TO PARTURIENT WOMEN.

BY WILLIAM DUNCAN, M.D., F.R.C.S.,

ASSISTANT OBSTETRIC PHYSICIAN AND LECTURER AT THE MIDDLESEX HOSPITAL.

(Concluded from page 65.)

3. *Laceration of the perineum* is, as Dr. Fordyce Barker says,[1] "an accident of parturition, which has occurred in the practice of the best obstetricians, and cannot always be prevented; but I believe that a thorough appreciation of the conditions under which it is liable to happen, and a judicious and timely use of means appropriate to each special condition to avert the danger, will render the accident a very rare one." Dr. Barker gives the following conditions as likely to produce it:—(*a*) A very straight sacrum; (*b*) a vulvar orifice more or less at right angles to the pelvic outlet; (*c*) an unyielding perineum; (*d*) extreme smallness of vulva; (*e*) a large fœtal head; (*f*) occipito-posterior and face presentations; (*g*) incomplete flexion; (*h*) very rapid or very tedious labours; (*i*) excessive irritability of patient; and (*j*) unskilful or instrumental interference. When once a laceration has begun, its extent depends, *pari passu*, on the rapidity with which the head and shoulders are delivered, being greater the quicker delivery is effected. Perineal laceration may be followed by hæmorrhage or septic poisoning; and, later on, owing to the partial destruction of the pelvic floor, rectocele and cystocele may occur, and these, in their turn, be followed by uterine prolapse, or other displacements of the pelvic viscera, with their accompanying evils. Now, what may we consider to be the best means of preventing perineal laceration? For my own part I have no faith in supporting the perineum, as I fail to see how it can be of use. Believing, as I do, that the majority of ruptures are due either to a too forcible and rapid expulsion of the head, or to a premature extension taking place before the nape of the neck is well under the symphysis pubis, so that the occipito-frontal, instead of the shorter sub-occipito bregmatic diameter, passes through the vulvar outlet, my mode of treatment is as follows:—When the head has come down on to the perineum, having well lubricated this structure with carbolised vaseline, I endeavour to regulate the rate at which the head distends it, and to maintain flexion by placing the fingers of the left hand towards the bregma, and those of the right on the occiput, and in this way am able, I think, to frequently stave off a rupture; if, however, notwithstanding this procedure, laceration seems impending, I make lateral incisions in the outlet, and, in not a single instance, in which I performed this simple operation of episiotomy, has the perineum itself given way, nor has there been any trouble subsequently from the incisions, which unite perfectly after the insertion of one or two catgut sutures. Since advocating this method, in a paper published in THE LANCET in 1884, I have only had occasion to incise the perineum laterally five times, but in each case with a successful result. However, since reading a paper by Credé on "Single Lateral Incisions for Perineal Ruptures,"[2] I am bound to admit that, in all probability, the double incision is unnecessary. (A good abstract of this paper appears in the Year-book of Treatment for 1885, from the pen of Dr. Champneys.) Credé thus describes the method in which the operation is performed at Leipzig. "One blade of a pair of strong straight scissors is inserted flatwise, between the vulva and head, about an inch from the fourchette; then, when the acme of the pain has passed, a cut is made outwards towards the tuber ischii (half to one inch long), and either through the skin, or through skin and muscle. It is important not to cut at the height of a pain, otherwise, owing to the rapid advance of the head, extensive laceration may take place; whereas, if performed as the pain is passing off, we can better regulate the extent of the incision, and the suffering is less than when the pain has quite passed away." Credé advises that the incisions be closed with silk. From an analysis of 2000 cases he gives the following table:—

I. PRIMIPARÆ (997).		
Lateral incisions	259 = 25·9	per cent.
Spontaneous ruptures	104 = 10·4	„
Rupture in spite of incisions ...	29 = 2·9	„
Perineal injuries ...	392 = 39·2	„
II. MULTIPARÆ (1003).		
Lateral incisions...	12 = 1·2	per cent.
Spontaneous ruptures	24 = 2·4	„
Rupture in spite of incisions ...	0 = 0	„
Perineal injuries ...	36 = 3·6	„
III. PRIMIPARÆ AND MULTIPARÆ (2000).		
Lateral incisions...	271 = 13·5	per cent.
Spontaneous ruptures	128 = 6·4	„
Rupture in spite of incisions ...	29 = 1·4	„
Perineal injuries ...	428 = 21·3	„

He sums up as follows: "Very rarely, and only in very unfavourable and exceptional cases, does laceration follow

Digitized by Google

incision; the oftener incision is practised the rarer are lacerations; complete ruptures are abolished; the lying-in is far more favourable after incision than after laceration. Incision prejudices recovery inappreciably or not at all; the vulva is not really damaged. Incision does not favour infection; the pain is trivial, and pain is saved by shortening the most painful stage of labour; by relieving pressure it helps to avoid sloughing."

In the event, however, of laceration taking place, I maintain that it is our bounden duty to bring the lacerated surfaces together by means of deep sutures, even though the tear be slight, and *a fortiori* when it is extensive, in order not only to lessen the risk of septic absorption, but to obviate ill effects, which may necessitate a secondary perineoraphy later on. My mode of procedure is the following: The patient lying on her left side with the legs well flexed; the nurse with one hand on the abdomen aids uterine contraction, and with the other raises the right knee well away from the left. A piece of sponge the size of an orange, and wrung out of an antiseptic solution, is passed into the vagina, in order to prevent blood trickling down and obscuring the rent; then the left forefinger is inserted into the rectum, and *the posterior vaginal wall pulled forward* so as to expose the whole extent of the laceration. This is now cleansed of all clots and sponged over with an antiseptic solution; then two or three sutures (I prefer wire, but silk or silkworm gut will do) are passed deeply, with a well-curved needle set in a handle, so as to include all the laceration; the two sutures nearest the anus are now twisted, then the sponge withdrawn from the vagina and the remaining suture rapidly secured. The sutures are left in for a week, the vagina kept free from discharge, in the manner to be mentioned presently. The bowels are kept quiet for five days, if the laceration be extensive, and especially if it involve the anal sphincter; but if it be slight, or there be any special indication for doing so, a mild dose of castor oil or other aperient may be given on the second day. Chloroform as a rule is unnecessary, unless the patient be very nervous; if administered at all, it must be given to the surgical degree. I would add that it is far more important for a practitioner to carry to every midwifery case some needles with wire or silk than a bottle of ergot.

4. *Post-partum hæmorrhage.*—Although this is a not uncommon accident of childbirth, it is in the fullest sense a preventable one, and only occurs frequently under one condition—namely, when the third stage of labour has been mismanaged. I cannot do better than quote Playfair's words on the subject.[3] "I believe that if this lesson were driven into the mind of the practitioner that every case [of midwifery] is to be treated as if hæmorrhage were about to occur, then it would be of the rarest possible occurrence. If I hear of a man who is always having hæmorrhage amongst his patients, I feel myself justified in concluding that that man either does not know or does not practise the proper management of the final stage of labour." My own experience leads me to endorse these words, for although the fact that, in an attendance upon just a thousand labours, not a single case of flooding occurred may be due to good fortune, I am disposed to attribute it to one's routine method of conducting each case. "When the child is about to be born, I get the nurse to spread both her hands over the uterus, to follow it up as it is being emptied, and to maintain firm pressure without intermission for a single instant after delivery until I relieve her; this I do after having separated the child, placed it comfortably aside, and washed my hands. I then slip my hands under those of the nurse, and, grasping the uterus (which almost invariably feels well contracted), I gently knead it, making pressure downwards and backwards towards the sacrum; the placenta is expelled usually in a few minutes by the *vis à tergo*; and under no circumstances whatever is the slightest traction made on the cord." This method, it will be seen, is very different from that advocated during the last few years by Credé, and which has become so widely adopted. He says: "It is chiefly important to utilise exactly the moment, and no time for pressure with the hand. The hand should be softly laid upon the uterine region; [illegible] stroking movements over the largest [illegible] of the uterus are made until a contraction [illegible] sets in, grasping with the outspread [illegible] one hand is insufficient with both hands) the uterus, and, at the moment when [illegible] seems to have reached its greatest energy, press [illegible] the fundus and walls of the uterus in the direct[illegible] hollow of the sacrum. To press upon the uterus during absence of a contraction, in order to remove the placenta, is entirely wrong, and does not fulfil its object." Credé says that the most advantageous, and at the same time perfectly harmless, period for the expression is the third or fourth contraction, which occurs about five minutes after birth; and he asserts that if after the lapse of half an hour the placenta has not been delivered, he regards the case as pathological and demanding manual intra-genital aid.

With regard to the curative treatment of post-partum hæmorrhage, I shall only remark that emptying the uterus of all clots, followed by the injection of hot water into its cavity, and of ergotine into the gluteus muscle, will prove sufficient for most cases, and that, considering the dangers attending the use of perchloride of iron injection, this should only be had recourse to in the most desperate cases; and, lastly, the frequent subcutaneous injection of ether will sometimes obviate the necessity for transfusion.

Such are the few remarks I have ventured to bring forward on some of the accidents to which parturient women are liable; but seeing that almost all the cases of septic poisoning occurring in puerperal women, and resulting in either pelvic cellulitis, pelvic peritonitis, or puerperal fever, are due to infection from without (hetero-infection), and few, if any, to auto-infection, I cannot refrain from laying stress, before concluding this paper, on the immense importance of the systematic adoption of strict antiseptic measures in the conduct of every midwifery case, not only on the part of the practitioner, who, as a rule, only touches the genitals during parturition, but more particularly on the part of the nurse. Assuming, then, that the sanitary arrangements, both of the lying-in chamber and of the house in which it is situated, are perfectly sound, I venture to suggest that every obstetric case should be conducted somewhat as follows:—The medical attendant, before visiting his patient, ought to feel confident that he does not carry in his clothes the means of infection. Before making a vaginal examination the hands should be thoroughly washed with carbolic soap-and-water, using always a nailbrush, and then the forefinger smeared with some antiseptic. (I always use a 1 in 500 solution of corrosive sublimate in glycerine.) The vagina is to be washed out before the birth of the child with a warm solution of either 1 in 40 carbolic acid, or 1 in 2000 sublimate.[5] For the five days following delivery the vagina is to be washed out night and morning with a 1 in 2000 sublimate solution, and from then until the lochia have ceased with a solution of half the strength. Any perineal laceration should be sutured, and in any case where it has been necessary either to apply the long forceps or to insert the hand into the uterine cavity, this latter should be washed out by means of a double pipe,[6] and then a 30-grain iodoform bougie passed well into the uterus. The nurse should take precisely the same precautions as the practitioner with regard to her hands before attending to her patient. She should be careful to remove all soiled linen from the room, and to keep the catheter and the vaginal pipe immersed in a basinful of 1 in 40 carbolic or 1 in 2000 sublimate solution. If every woman's lying-in were to be conducted on the lines above indicated, it seems to me we should very rarely meet with that fearful malady, puerperal fever.

[illegible] Int. Congress, 1881, vol. iv., p. 387.
[illegible] Gynækologie, 1881, p. 284.

[5] Messrs. Calvert of Manchester have made an elegant 20 per cent. carbolic soap, with case for carrying in the waistcoat-pocket; and also a granulated phenol, which is readily soluble in warm water without any deposit. Professor Helferich has invented sublimate tampons, the contents of each one of which, dissolved in two pints of water make a 1 in 1000 solution.

[6] Messrs. Down Bros. of St. Thomas's Street, S.E., have made a very good one for me.

DONATIONS.—Baron de Hirsch, in memory of his son, Lucien de Hirsch, who had a large racing establishment at Newmarket, has in consequence of the breaking-up of that establishment devoted the proceeds, amounting to £12,000, to public charities, amongst which are the following:—Metropolitan Provident Medical Association, £3000; London Hospital, £1000; Rous Memorial Hospital at Newmarket, £1000; Children's Hospital, Great Ormond-street, £500; and North-Western Hospital, £500.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

ORIGIN OF TUMOURS BY REVERSION.

BY HARRY CAMPBELL, M.D., B.S. LOND., M.R.C.P.,
ASSISTANT-PHYSICIAN AND PATHOLOGIST TO THE NORTH-WEST LONDON HOSPITAL.

THE interesting communication of Dr. Gresswell on the above subject has suggested the following brief remarks.

I have been inclined for some little time past to regard certain new formations as reversions—of limited patches of tissue—to an ancestral type, notably the enchondromata, myxomata, sarcomata, and the new formation occurring in consequence of inflammation—namely, granulation tissue—including, of course, the granulomata. It must not be forgotten that the reversion of which Dr. Gresswell speaks is not the ordinary reversion which occurs during the embryological development of an organism, but the reversion of a fully evolved and specialised tissue to one of remote ancestral type. That such a fully-developed tissue may thus revert is a well-recognised fact. Dr. Maudesley points out that during the cerebral disturbance which heralds an attack of insanity, the moral faculty—namely, that mental element which has been last acquired, is generally the first to go. This shows a reversion of cerebral tissue to an ancestral type. It is well to bear in mind that the tissues of a fully-developed organism have many potentialities which only need fitting opportunities to display themselves. These consist in modifications of cell environment. A good example of such latent capacities is afforded by disease, atrophy, or removal of the ovaries or testicles, when the organism tends to take on the characters of the opposite sex. This shows that each sex contains potentially the actualities of the other, and similarly the most highly specialised organism contains the potentialities of remote ancestral actualities which display themselves under modifications of cell environment.

As regards tumours, the nature of this environment is known in certain instances, as in the granulomata; parasites enter the tissues, and so disturb the cell environment that they can no longer maintain their high grade of specialisation and revert in consequence to an ancestral type. The malignant tumours have, I believe, a like parasitic origin; but there is no need here to adduce arguments in favour of this view. Now, sarcomatous tissue is distinctly of an ancestral type; one cannot, however, speak so positively of the carcinomatous. In epithelioma, however, we see changes allied to embryological ones. The squamous epitheliomata originate by an involution of the epithelium, such as occurs in the development of all open glands (even the liver is thus developed); but in this instance the inverted cylinders have no lumen, nevertheless the manner of development is that of a crude form of gland. In the cylindrical variety we have a higher effort, for a distinct lumen is developed. I cannot compare the other carcinomata to any embryological or ancestral tissue through dearth of knowledge; but let us bear in mind that the affected tissues must possess the potentiality of this mode of growth, and whence, it may be asked, have they this power? I should not be surprised if one of wide histological knowledge could throw light upon the subject on the lines laid down by Dr. Gresswell.

Guilford-street, W.C.

SUPRA-PUBIC LITHOTOMY.

BY CHARLES WILLIAMS, F.R.C.S. ED.,
SURGEON TO THE NORFOLK AND NORWICH HOSPITAL.

GEORGE J——, a farm labourer, aged eighteen, was admitted into the above institution in May, 1886. He had suffered from constant irritability of the bladder from the age of two or three years, and from well-marked symptoms of stone for twelve months. Of late the vesical pain had been excessive, and had greatly impaired his health. He was thin and worn, stooped much, and was inclined to have his left hand constantly in his trousers-pocket, grasping his penis—a sure sign of stone in the bladder. There was no indication of kidney impairment. The lithotrite gave evidence of a rough stone of about an inch and a half in diameter.

June 25th.—Hypogastric lithotomy was performed, the bladder having been injected with six ounces of boracic acid solution through a No. 9 silver catheter, known as Brodie's, which was retained and held by my colleague, Mr. Crosse. This proceeding rendered the rectal bag unnecessary, and proved to be a sure and safe guide to the viscus, which I was enabled to open without difficulty. The stone was extracted without trouble, and a medium-sized rubber tube placed in the lower portion of the wound. The vesical incision was brought together by means of several catgut sutures, and the abdominal wound closed by six carbolised silk sutures. The patient was placed on his side in bed, and with a small basin was enabled to catch the urine as it ran through the drainage tube.

Two days later redness and tension were noticed around the wound; some sutures were removed and a teaspoonful of pus escaped. On the fourth day the tube was removed, and on the fifth the urine passed per urethram.

On July 31st the patient left the hospital in excellent health, the wound soundly healed. The stone weighed 509 grains, and consisted of uric acid.

Norwich.

NOTE ON THE ADMINISTRATION OF OPIUM.

BY A. G. AULD, M.D.

THERE are few drugs more commonly prescribed than opium, and it is certain there is none more abused or more carelessly combined. Of its numerous official preparations it cannot be said that their individual actions are free from the disagreeable after-effects which characterise that of the pure drug. The problem is to get all the good effects of the drug, and yet to obviate the resulting headache, sickness, and loss of appetite caused by arrestment of the secretions of the alimentary canal. This, of course, refers to medium doses. Belladonna or atropia have for long been given in combination with opium, but in these respects the result has been mostly a failure, the reason being that while the actions of these drugs on the central nervous system are to a certain extent antagonistic, their actions on the alimentary secretions are much the same. For some time I have given opium in combination with ether with good results, ether being one of the most powerful secretion stimulants we know. I generally prescribe equal quantities of tincture of opium and spirit of ether, and though not claiming for this a specific effect, think it a good and most useful mixture.

Wick, N.B.

SEVERE CASE OF ACUTE GLOSSITIS.

BY BERNARD RELTON, M.R.C.S., L.S.A.

AT 1.30 A.M. on May 29th I was called up to go immediately to see a man, a painter by trade, aged about thirty, whose "tongue was so swollen that he was being suffocated." On interrogating the messenger, I learnt that the patient had had a heavy supper of oysters, cucumber, onions, and whisky at 11 that evening, and shortly afterwards his tongue and neck began to swell rapidly, and that he was now almost choked. I went to the man immediately, and found him sitting up in bed with his mouth wide open, and protruding from it a red mass which completely filled up the aperture of the mouth, while the unfortunate man was gasping for breath and appeared almost moribund. Seeing the danger he was in, I determined to make free incisions into the tongue; but on pulling down the lower lip I found the floor of the mouth so very swollen and œdematous, and the immensely swollen tongue pushed up so high, that I freely punctured with a "Paget" knife the swollen tissues beneath the tongue, from which a considerable quantity of serum rapidly oozed out. I was now able to get the handle of a spoon on the dorsum of the tongue, and pressed it down hard, so as to give him a better chance of breathing, and this made him very sick. The vomited matter, more than a pint in quantity, consisted of improperly digested food, and smelt strongly of onions. He now began to breathe much better and in the course of ten minutes, or even less, he was able to move his tongue, which before was

Digitized by Google

quite impossible, and soon after he was able to close his mouth. The submaxillary glands, which on my arrival were greatly swollen on the right side, and looked like a huge submaxillary new growth, now began to subside, and half an hour after entering the house I left, leaving the man out of danger, although still breathing with difficulty. I called again about 9 A.M., and found the patient sitting up in bed. On asking him how he felt, he replied, "I am quite well now; it was those oysters poisoned me." On asking him how he could tell, he told me that when he swallowed them they had a nasty coppery taste, which he noticed again directly the vomiting came on.

When I was at St. Thomas's Hospital I saw two cases of acute glossitis, but in neither of them were the symptoms to be compared in severity with the above. I may add that, besides the puncturing, I applied hot water fomentations to the neck, and inhalation of steam after the vomiting, but I do not consider they had anything to do with the successful issue of the case.

UNIVERSITY COLLEGE HOSPITAL.

SCIRRHUS OF THE PANCREAS, CAUSING INTESTINAL OBSTRUCTION; COLOTOMY; DEATH; NECROPSY.

(Under the care of Mr. MARCUS BECK.)

THIS case is unusual in many respects; it is not common to find scirrhus affecting the pancreas as a primary growth. When malignant disease affects that organ it is mostly as an extension from a neighbouring part, such as the stomach. Here there can hardly be a doubt, from the careful examination made after death, that the disease commenced in the pancreas, and produced the symptoms of intestinal obstruction by extension to the colon. It is well known that malignant stricture of the bowel is by far most common below the descending colon (Brinton, 60 per cent.), and therefore the indication where the position of the stricture is doubtful, is either to perform colotomy, as in this instance, on the left side, proceeding after failure to a similar operation on the right side, or to perform abdominal section, and after the discovery of the seat of obstruction, proceed to the opening of the bowel above the position of the disease, in the most convenient situation. The course adopted will vary in different cases, and in the practice of different surgeons, but where the seat of obstruction is probably in the large intestine, most would proceed in the manner adopted with success by Mr. Beck. For the following notes we are indebted to Mr. W. B. Ransom, dresser to the case.

James B ——, a cabdriver, aged fifty-seven, was admitted into University College Hospital at 2 P.M. on June 11th, 1887, with a history of complete intestinal obstruction since June 1st. On the 30th of the previous month he felt some discomfort in the abdomen, and lost his appetite. The next day (May 31st) he passed two small hard lumps of fæces, but nothing since that date in spite of the repeated administration of jalap, castor oil, and enemata. On June 1st he vomited some white slimy matter, but that was the only occurrence of sickness. The next day he was seized with violent cramp pains all over the abdomen, which on the evening of that day became much swollen. The pains continued up to the time of admission into the hospital. During the eleven days of obstruction he was fed on gruel and milk.

On admission the patient lay in a prostrate condition, and complained of severe pains shooting all over the abdomen. The abdominal walls were considerably and uniformly distended, and were tympanitic both in front and in the flanks. No intestinal movements could be seen, but some rumbling was felt. No special tumour could be detected by the touch, and nothing was discovered in the [illegible] pulse was full and strong, and no cardiac bruit [illegible] The patient had slight scalding pain during mi[illegible] The urine was high-coloured, acid, sp. gr. 1040, fr[illegible] sugar and albumen, but contained an excess of uric [illegible] The previous history gave no evidence of syphilis, typ[illegible] fever, or dysentery. There was an obscure history of [illegible] acute attack of abdominal pain, vomiting, and intestinal obstruction in 1856, when the patient was a soldier in the Crimea. For the last three years he has been habitually costive, the bowels being only opened by the use of jalap. There was no family history of cancer.

From the history of the attack and the distension of the flanks, it was thought that the seat of the obstruction was in the large intestine, probably in the sigmoid flexure, and accordingly two hours after admission Mr. Beck performed left lumbar colotomy. But when the descending colon was opened neither gas nor fæces escaped through the incision, although the abdominal tension caused the gut to protrude through the wound. The finger inserted into the colon could not reach the seat of obstruction. The wound was therefore stitched up, covered with iodoform wool, and the patient turned over and the ascending colon opened. From this incision a large quantity of gas and liquid fæces immediately issued, and when the patient was returned to bed he at once expressed his sense of relief.

On the next day, June 12th, a free discharge of liquid fæces continued from the right colotomy wound, and the patient felt comfortable. Temperature at 11 A.M., 99·4°. The wound on the left side was found to be fairly clean, and was covered up with iodoform wool and collodion. During the next two days, however (13th and 14th), this wound became foul, and showed a brownish discharge of fæcal appearance and smell. The sutures became loose, and the wound gaped widely by the 16th. Temperature at 11 A.M. on the 14th, 101·8°. This discharge from the descending colon ceased to be fæcal by the 18th, but a considerable quantity of white mucus continued to escape. The abdominal distension and tenderness became by this time very slight, and the appetite returned. The fæces continued to escape from the right colotomy wound, but became more solid. Improvement continued up till the 21st, and the patient slept well, and was able to eat meat. During these days there was no great rise of temperature—e.g., on June 20th, at 11 A.M., the temperature was 99·4°; at 7 P.M., 100·4°; but after the 21st it was never below 100°. The abdominal pains returned, and the patient, though apparently drowsy by day, hardly slept at all during the night. On the night of the 26th he vomited three or four times, bringing up food and bile-stained fluid. He was also at times somewhat delirious. On the 27th, at 11 A.M., the temperature was 103°, and the vomiting was twice repeated. After having some brandy he seemed easier, and at night slept better, being only sick once. Temperature at 11 P.M., 102·6°. On the morning of the 28th he seemed better, got shaved, and smoked two pipes between 7 and 8 A.M., but before 9 A.M. he died. Temperature at 5 A.M., 101·2°.

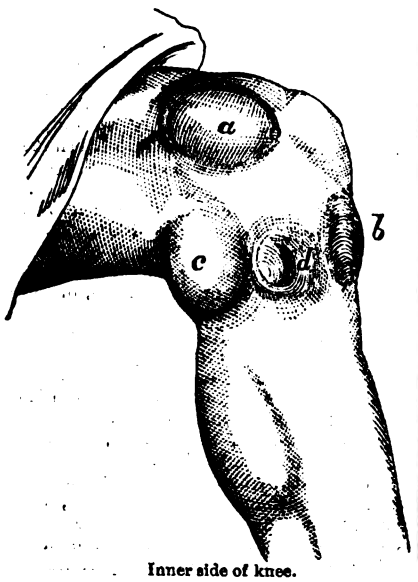
The suddenness of the death, when the patient was fairly comfortable, and to all appearance distinctly better, was a remarkable occurrence, which the necropsy failed to explain, while the changes observed post mortem rendered further remarkable the slight amount of discomfort experienced by the patient since the operation.

Necropsy, twenty-six hours after death.—The intestines were found to be matted together by a thin layer of yellow lymph, and to be in many places adherent to the abdominal walls. One large and several small perforations were seen in the small and large intestine, but all were closed by adhesions. The peritoneal cavity contained neither fluid nor fæces, and there was no special inflammation round the colotomy wounds. The sigmoid flexure and descending colon on being opened proved to be empty and free from tumour or stricture; but at the splenic flexure the colon was much constricted, and the mucous membrane puckered into numerous folds. Otherwise the interior of the colon at this spot presented no abnormality, but on section through the puckered region the muscular coat of the colon was found to be continuous with a hard, dense, white mass, which bound it down to and extended into the tail of the pancreas, the spleen, and the left kidney. To the naked eye the growth appeared to extend into the pancreas for about an inch, but only into the capsules of the kidney and spleen.

Microscopical examination of the growth showed it to be a scirrhous cancer affecting chiefly the last inch of the tail of

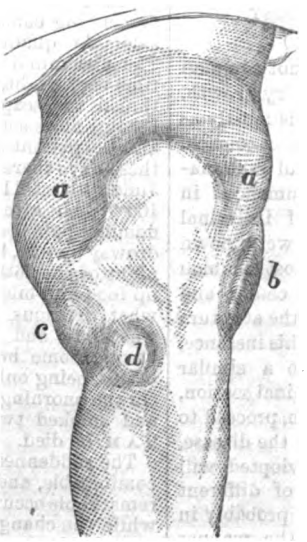
Digitized by Google

the pancreas. Normal pancreatic gland tissue was found in its immediate vicinity. The capsule of the spleen and a thin layer of the splenic pulp were completely destroyed at the place of contact with the growth, the stroma of which contained broken-down blood pigment (hæmatoidin?) in the region which had invaded the spleen. A portion of the cortex of the kidney was destroyed, and in the zone in front of the growth there was great infiltration of leucocytes and signs of degeneration of glomeruli and tubules. The invasion of the colon by the cancer cells was mostly limited to the muscular coats, but here and there the submucous coat was penetrated, and at these points the mucous membrane was so infiltrated with leucocytes as to appear on the point of ulcerating into the lumen of the gut. But at no point was there any proliferation of the epithelial cells of the colon, while the cells of the tumour throughout showed the typical arrangement of scirrhous cancer, and in the substance of the pancreas were continuous with masses of normal gland cells, with which they were almost identical in appearance. There was thus no room for doubt that the growth originated as a carcinoma of the pancreas.



LEEDS GENERAL INFIRMARY.

MULTIPLE ABNORMAL SYNOVIAL CYSTS AROUND THE KNEE.



(Under the care of Mr. A. W. MAYO ROBSON.)

THE following case was reported and the drawings made by Mr. W. B. Russell, B.A.

J. P——, aged fifty-three, was admitted on March 23rd, 1886, complaining of pain and stiffness of the left knee. The patient, an out-door labourer, exposed to cold and wet, had for eight years suffered from rheumatic pains in both knees. About eight months before admission, without apparent cause, a swelling formed about his left knee, accompanied by considerable pain and lameness; the leg also became swollen as far as the ankle. He was treated as an out-patient by means of Scott's dressing and elastic bandage, which relieved him, but there had been swelling around the knee ever since, and lately the pain and lameness had increased.

Inner side of knee.

Front view.

a. B. under vasti. *b*. B. under biceps. *c*. B. under semi-membranosus. *d*. B. under sartorius.

On admission there was much swelling around the left knee, which was flexed to an angle of 150°, and could not be extended without pain. The swelling was markedly fluctuating in four distinct parts. (See diagrams.) 1. Above and on each side of the patella, extending under the vasti, was a large fluctuating sac, which did not cause a bulging below the patella when pressed on. 2. Above the head of the fibula, in connexion with the biceps tendon, was an oval, well-defined swelling the size of a [illegible] and tender on pressure. 3. On [illegible] semi-membranosus was an [illegible] tuating sac, which was rather smaller than *b*. 4. In front of *c*, and extending a little lower and more forward, was a sac less tense than the others, and evidently communicating by means of a small opening with *c*, for the fluid could be pressed back so as to make the sac *c* more tense. The internal saphena vein was somewhat varicose, especially above the knee. The knee jerk could be tried with difficulty owing to the swelling, but when obtained the leg remained extended for a few seconds. The other reflexes were normal. He could stand with his eyes closed. The patient was well in every other respect, and got on so comfortably with a Thomas's splint that he would not have any active treatment, and was at his own request made an out-patient.

Remarks by Mr. MAYO ROBSON.—That the case above recorded is an unusual one is proved by the fact that several of my colleagues had not seen a similar one. In the thirteenth volume of the St. Bartholomew's Hospital reports is a paper by Mr. Morrant Baker on several cases of a like nature, in which he comes to the following conclusions:—"1. That in cases of effusion into the knee joint, and especially in those in which the primary disease is osteo-arthritis, the fluid secreted may find its way out of the joint, and form by distension of neighbouring parts a synovial cyst of large or small size. 2. That the synovial cyst so produced may occupy (*a*) the popliteal space and upper part of the calf of the leg, or may (*b*) be evident in the calf of the leg only, projecting most, as a rule, on the inner aspect of the leg as a small defined swelling, not approaching within three or four inches of any part of the knee joint. 3. That however large the synovial cyst may be, fluctuation may not be communicable from it to the interior of the knee joint; but the absence of such fluctuation must not be taken to contraindicate the existence of a connexion between the joint and the cyst. 4. That the synovial cyst may be expected to disappear after a longer or shorter period without leaving traces of its existence, even on dissection of the limb. 5. That the cyst should not be punctured or otherwise subjected to operation, unless there appear strong reasons for so doing, inasmuch as interference may lead to acute inflammation and suppuration of the knee joint. 6. That most often the disease in the knee joint will be found to have begun some time before the appearance of the secondary synovial cyst; but sometimes the patient's attention may be first drawn to the latter, or the cyst may seem for a long period the more important part of the disease." With such recorded experience I felt that there were only two courses open to me in treating a patient over fifty, these being amputation or palliative means; and as the latter answered so well, the patient took the responsibility into his own hands, and elected to be relieved with his limb on. I have seen abnormal synovial cysts in close and intimate connexion with other joints—e.g., ankle, wrist, shoulder, and in one case with the back of the hip joint, but in no example have I found them so extensive or producing so much deformity and lameness as in the case related, which, though differing in several points from Mr. Morrant Baker's recorded cases, is evidently essentially of the same nature.

KIDDERMINSTER INFIRMARY AND CHILDREN'S HOSPITAL.

GASTROSTOMY IN A CASE OF MALIGNANT STRICTURE OF THE ŒSOPHAGUS; DEATH; NECROPSY; REMARKS.

(Under the care of Mr. J. LIONEL STRETTON.)

J. M——, aged fifty-seven, was admitted on July 22nd, 1886. He complained of difficulty in swallowing and regurgitation of food; he could not swallow any solids. There was [illegible], and a large œsophageal bougie passed easily, meeting with some slight resistance opposite the cricoid cartilage. He was ordered milk *ad lib.* and four ounces of [illegible] daily; the bougie to be passed once or twice a week.

Aug. 5th.—The difficulty in swallowing has increased, the

Digitized by Google

effort apparently causing spasmodic stricture. The bougie meets with more obstruction in the cricoid region, and a hardened feel is apparent internally. Ordered to have two pints of milk, two eggs, and four ounces of brandy injected daily. He has lost flesh considerably.

His condition continued to get worse; he was becoming rapidly thinner, and the tubes for the injection of the milk had gradually to be reduced in size.

Oct. 1st.—Nothing larger than a No. 10 catheter can be passed. This does not cause much pain, and the nourishment is injected through it.

15th.—The patient is now unable to get up, but still takes nourishment freely by injection.

20th.—The difficulty is much increased, and it is doubtful if the catheter passes the stricture. To be fed on nutrient enemata. Ice and brandy by the mouth.

23rd.—After consultation with his colleagues, Mr. Stretton decided to perform gastrostomy.

The usual incision was made and the stomach stitched to the edges of the wound, the peritoneum being included in the sutures. No opening was made in the stomach. The operation was well borne. He was ordered a grain of opium every four hours, and to be fed with nutrient enemata. In the evening he was quite comfortable and free from pain. Temperature 99·6°; pulse good.

24th.—Temperature 98·4°; pulse regular and of good volume. Is taking nourishment well by the bowel.

25th.—Has had a fair night. Temperature 99·6°; pulse good. Complained of slight pain.

26th.—4 A.M.: He became very weak, and could not retain the enemata. 11 A.M.: At Mr. Stretton's visit he was found to be exceedingly prostrate. It was determined as a last effort to open the stomach and inject some brandy-and-milk, but before this procedure could be carried out he passed away, apparently from exhaustion, quite free from pain.

Necropsy.—Body much emaciated. On opening the abdomen the stomach was found to be adherent to the abdominal walls adjoining the external wound, the stitches intact, and there was some local peritonitis and flakes of lymph. The stomach, which was much retracted, was removed, together with the adherent abdominal wall and the œsophagus. In the course of the œsophagus there was a growth about the size of a small walnut just below the level of the cricoid cartilage, which only allowed the passage of a blowpipe. The other organs were healthy. No enlarged glands were discovered.

Microscopic examination by Professor Barling showed the growth to be a spheroidal-celled carcinoma of the scirrhous variety, with typical alveolar structure.

Remarks by Mr. STRETTON.—The above description of the growth will probably account for the failure of treatment by bougie, which would be more likely to afford relief in the softer varieties of carcinoma and epithelioma more commonly met with in this region. The operation was only undertaken as a last resource, with the full consent of the patient, who stated that he would rather die under it than continue his miserable existence. I feel confident that had it been undertaken earlier the result might have been otherwise; but we, as the patient, were wishful to try all other means first. In future cases when there is no marked relief by bougie treatment, I should not hesitate to urge the operation at a much earlier date before the powers are so much diminished.

PRESENTATIONS.—Mrs. Wardroper has been presented with a handsome silver coffee and tea service, with salver and the following inscription: "This salver, with accompanying service, was presented to Mrs. W. W. Wardroper, on her resignation of the matronship of St. Thomas's Hospital, by the present and present probationer nurses of the Nightingale Fund Training School, over which she has presided from the beginning, for twenty-seven years, as a grateful appreciation of the inestimable services rendered by her to the profession of nursing, and as a token of regard and esteem. June, 1887."—The Master of the Jubilee Victoria 1895 of the Ancient Corporation of Canterbury, last week presented the Recorder of Kingston (Mr. Henry George Sadler) with a handsome marble time-piece, on the occasion of his marriage with Mr. Henry Octavius Preston, [illegible]

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Ophthalmoplegia. — Quinine Amblyopia. — Sympathetic Ophthalmitis occurring after Evisceration.

A MEETING of this Society was held on Friday, July 8th, Mr. Jonathan Hutchinson, F.R.S., Vice-President, in the chair.

Mr. JONATHAN HUTCHINSON, jun., read the notes of a post-mortem examination of a case of Ophthalmoplegia Externa and Interna. The patient had been in the Bancroft-road Infirmary under the charge of Dr. Robinson, who furnished the clinical notes of the case. There was considerable defect of vision, due to nearly complete paralysis of the oculo-motor nerves of the right eye; persistent pain in the forehead and temple was complained of, and there was some proptosis and congestion of the lids. At the necropsy there was found a chronic inflammatory process about the right cavernous sinus, which had produced inflammation of all the nerves in its wall, the lumen of the sinus had become obliterated, there was partial obstruction of the internal carotid artery, and the apex of the right temporo-sphenoidal lobe was firmly adherent to the adjacent dura mater. The lesion was most probably due to syphilitic poison, the cause of the patient's death being cellulitis round a specific ulcer of the leg. He referred to two cases of unilateral ophthalmoplegia externa and interna, in which the symptoms were precisely similar to those of the present case; these were treated with potassic iodide, and each made a good recovery. He suggested that these cases were also due to syphilitic inflammation about the cavernous sinus, and laid stress on the fact that the sixth nerve (lying furthest away from the wall of the sinus) being involved the latest and to the least extent, and also the involvement of the ophthalmic division of the fifth nerve (shown by severe frontal pain or anæsthesia) pointed to this view of the pathology rather than to central nuclear degeneration. In another case there was internal ophthalmoplegia with ptosis, and the lesion was probably of cerebral origin. He related also a case of double ophthalmoplegia interna in a young man. In the whole of these cases a distinct history of syphilis was obtained, or there was good reason to suspect its presence. Where the lids were congested together with proptosis one should suspect disease involving the cavernous sinus, and in these cases the condition of the retinal veins should likewise be noted.—Mr. J. B. LAWFORD gave the history of a case of double ophthalmoplegia externa. The patient was a man sixty years of age, who, apart from trouble with his eyes, was quite healthy. For ten years he had had almost complete ptosis. The eyes moved scarcely at all in any direction. The fundus of each eye was normal, and there was no paralysis of the intraocular muscles. No history of syphilis could be obtained, and there was no sign of cerebral or spinal mischief.—Mr. HUTCHINSON pointed to Mr. Lawford's case as typical of the symmetrical form of external ophthalmoplegia, and such cases usually remained in this condition without extension or complication. When syphilis was the cause, the disease usually was symmetrical in its whole course, and usually also cerebral in position. He quoted a case much like that of Mr. Lawford's which had remained in almost the same condition for twenty years. The patient was in good health, but there was a previous history of syphilis, and he applied too late for treatment to be of benefit. He referred to another case, that of a young lady in good health, where there was no suspicion of syphilis, and in whom the disease was very gradual. In another case in which recovery took place to a surprising degree the primary cause seemed to be an injury. In tabes dorsalis it was not unusual to find paresis of a single ocular nerve, the disease progressed very rapidly, was usually asymmetrical, and was nearly always recovered from. Such cases were due more probably to a syphilitic neuritis than to central disease. He had known in such cases recovery to be spontaneous. There was yet another class, separate from the rest, in which the disease was equal on both sides, progressed very gradually, all the muscles being affected, and recovery rarely or never following. The interest in his son's case lay in the fact of the rarity of syphilitic phlebitis. He thought it would be a convenience to give the two groups of cases different names,

Digitized by Google

though he was unprepared at the time to suggest new terms. He briefly related the particulars of another case in which the lesion was unilateral, and the cause an aneurysm of the internal carotid pressing on the cavernous sinus. He inquired, in conclusion, whether there were any definite symptoms (apart from orbital periostitis or neuritis) by which thrombosis of the cavernous sinus could be diagnosed.—Dr. MULES alluded to a case of general miliary tuberculosis in a young married lady. She developed symptoms of internal and external ophthalmoplegia, first in one eye and then in the other, and died with symptoms of basic meningitis.—Mr. MACKINLAY agreed with Mr. Hutchinson that in tabetic cases with unilateral ophthalmoplegia recovery often followed without the administration of iodide of potassium.—Dr. ORD said that in his experience the unilateral cases were very commonly curable, whilst the symmetrical ones obstinately resisted treatment.—Dr. SIDNEY COUPLAND referred to the paper he had read earlier in the session on thrombosis of the cavernous sinus. He was glad to find that the observations of Mr. Hutchinson, jun., bore out the remarks he then made. Where the sinus was diseased, in the greater number of cases the other side was affected later on. He believed that a considerable number of these cases was due to disease of the sinus.—Dr. ANDERSON was inclined to think that there was a form of unilateral external ophthalmoplegia which was of cerebral origin, and incurable. He believed the following symptom would prove of value in diagnosis: When the lid of the affected side was raised, the sound one drooped to a corresponding amount, and rose when the drooped eyelid was allowed to fall. He had seen one case in which the healthy lid closed when the affected eye was covered.—Mr. HUTCHINSON, jun., in reply, could not be sure that in his case the disease originated in the sinus. It might have commenced there, and it certainly involved early the structures in its neighbourhood. He could not be sure about the condition of the retinal veins. He thought it would be very difficult to arrange the cases in classes for a fresh nomenclature.—Mr. LAWFORD was inclined to think that in his case the disease was of wide extent and of central origin.

Mr. NETTLESHIP related two cases in which Temporary Amblyopia had followed the internal administration of Quinine. One of the patients had an idiosyncrasy to the drug, which even when administered in small doses caused gastric disturbance, and on two occasions previously had brought on temporary failure of vision. The second case he called a good classical instance of quinine amblyopia.—Mr. DOYNE inquired whether any alteration in the calibre of the arteries had been noticed. He had found the arteries very much contracted in a case of quinine amblyopia, afterwards the discs became whitened, though ultimately the sight became fairly normal.—Mr. NETTLESHIP, in reply, believed the arteries were always small during the stage of amblyopia. He did not know of a single case of complete permanent blindness from this cause, though in some cases which recovered the fields were small and the arteries constricted.—Mr. HUTCHINSON alluded to the great interest of the subject of visual lesions dependent on food or drugs. He quoted a case in which it was clearly proved that coffee had caused temporary deafness.

Mr. CROSS related two cases of Sympathetic Ophthalmitis occurring after Evisceration. G. R——, aged forty, came with a wound of the left eyeball over the ciliary region, but free of the cornea, occupied by slight choroidal protrusion. The iris was inflamed, the pupil tied, the lens had escaped. The wound had been made ten days before, and vitreous had escaped. Seventeen days after the accident evisceration was done antiseptically under the spray, and a glass vitreous introduced. The operation relieved pain, was followed by considerable swelling of the lids, and discharge. In a week he was quite comfortable. Conjunctival chemosis, somewhat resembling hæmorrhoids, continued for some time; as this subsided, the glass ball was seen exposed. There was scarcely any discharge, and no discomfort. Nothing was complained of or suspected in the right until seventeen days after the operation, when the patient had dull vision and discomfort in the eye. Two days later there was distinct sympathetic ophthalmitis. The ball was removed at once, leaving the sclerotic a rigid hollow cup, which moved freely like the opposite eye. Secretion was retained. The eye was much inflamed and painful for a fortnight, and he left five weeks after removal of the ball, some circumcorneal injection and irritation remaining. Mr. Cross had recently seen him again, and the eye was perfectly normal; there was not even uvea on the lens.—J. L., aged fifty, was seen three months after a wound of the right cornea. The cornea and eye were chronically inflamed; there was iritic prolapse. The other eye was quite healthy. Evisceration and metal vitreous. Considerable inflammatory swelling and discharge lasted a week. Twelve days after the operation the ball was exposed through a small fistula; it was at once removed. In ten days the patient left. In a few days he returned, saying that after a short exposure to sunlight on the day he left, he found the sight impaired. Vision $\frac{20}{40}$ J. 4; slight circumcorneal injection; sluggish pupil, which yielded to energetic atropisation, leaving slight uvea; vitreous hazy; distinct neuro-retinitis; very red, without exudation or hæmorrhages. Gradual improvement followed. In this case the sympathetic ophthalmitis showed itself twenty-one days after operation and four months from the injury. The symptoms subsided after ten weeks' treatment. These cases were considered to be analogous to those of sympathetic ophthalmitis occurring after and in spite of enucleation, and not caused directly by the operation. A case was quoted where a child aged thirteen years had her eye removed sixteen days after a corneal wound. Forty-two days after the injury, and twenty-six days after removal of the eye, slight sympathetic ophthalmitis came on, but recovered after two months' treatment. He considered that enucleation was very superior to evisceration when sympathetic ophthalmitis threatened; it more thoroughly removed the exciting disease, gave earlier and more complete physiological rest, and thus tended without delay to resolution of the morbid process where this might have advanced beyond the part removed. There was a special danger from the incomplete inclusion of the artificial vitreous. A septic fistula might result from imperfect healing, or, later on, from wearing out of the conjunctiva between the false eye and the artificial vitreous.—Dr. MULES said that nothing was claimed for evisceration over enucleation in regard to sympathetic ophthalmitis. He did not remember to have read of other cases in which this sequence existed. He thought the first case should be looked upon as one simply of iritis, for recovery had followed in ten days without descemetitis, whereas sympathetic serous iritis was always a slow process. He knew of no clinical distinction between non-traumatic serous iritis and sympathetic ophthalmitis. There could be no doubt that the second case was one of sympathetic ophthalmitis developing late. In cases of this kind in which there was much pain he had found great benefit follow the use of the horsehair drain and the ice bag.—Mr. DOYNE considered it to be bad surgery to practise evisceration in cases of tumour of the eyeball.—Mr. BRAILEY had seen many instances of sympathetic ophthalmitis which had run a mild course and subsided rapidly and completely. He did not consider descemetitis essential, and the dots were frequently absent. He had obtained good results in many cases of evisceration, but he had not put in a glass ball. He regarded choroiditis as a contra-indication to the performance of the operation.—Mr. MCHARDY looked upon these cases as instances of true sympathetic ophthalmitis. There must sometimes be an early stage and mild form of that disease. He attributed Mr. Cross's success to the fact that he removed the exciting cause.—Mr. CROSS, in reply, said that evisceration was a valuable operation in certain suitable cases, but it should not be performed where there was sympathetic ophthalmitis. In his cases the globe had not entirely healed, and he thought the wound thus left had something to do with the causation of the sympathetic disease.

The following living and card specimens were exhibited:—Mr. Spencer Watson: (1) Sequel to a case of Hæmorrhagic Glaucoma; (2) A case of Serpiginous Nebula of Cornea. Mr. R. N. Doyne: A new Optometer.

The annual general meeting was held at 9.30 P.M. The report of the Council was read. There are now 205 members of the Society, twenty-five of whom are non-resident. There had been fourteen admissions and three deaths since the last annual meeting. Reference was made to the fact that Professor Zehender of Rostock had delivered the last Bowman lecture, and that Mr. Henry Power had kindly undertaken to deliver the next. A large number of donations had been made to the Library, amongst which must be mentioned a series of von Graefe's Archives, presented by Mr. James Dixon of Dorking. The annual report of the treasurer was presented.

The following officers and Council were elected for the year 1887-88:—President: John Whitaker Hulke, F.R.S.

Digitized by Google

Vice-Presidents: Mr. Jonathan Hutchinson, F.R.S.; Dr. George Johnson, F.R.S.; Mr. E. Nettleship; Dr. D. Argyll Robertson (Edinburgh); *Mr. Priestley Smith (Birmingham); and Mr. T. Sympson (Lincoln). Treasurer: Dr. William M. Ord. Secretaries: Mr. Seymour J. Sharkey and Mr. Robert Marcus Gunn. Other Members of Council: Dr. John Abercrombie, Dr. W. A. Brailey, *Mr. Edgar A. Browne (Liverpool), Dr. Sidney Coupland, Mr. Walter Edmunds, Mr. H. E. Juler, Mr. William Lang, Dr. J. B. Lawford, *Mr. M. M. McHardy, Mr. A. Stanford Morton, Dr. P. H. Mules (Manchester), and Mr. J. B. Story (Dublin). Librarian: Mr. W. Adams Frost.

The gentlemen whose names are marked with an asterisk (*) were not in the Council, or did not hold the same office, during the preceding year.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, July 6th, Dr. John Williams, President, in the chair.

Dr. STEAVENSON showed a number of instruments used in electrolysis, including a set of electrodes, &c., as used by M. Apostoli of Paris.

Dr. HORROCKS exhibited a specimen of Chronic Endometritis with microscopical sections.

Dr. W. S. GRIFFITH showed a drawing and section of a Uterus in which a "contraction ring" was well seen. It was removed shortly after a labour terminated by Cæsarean section.

Dr. LEWERS showed a Fibroid Tumour removed from the anterior vaginal wall.

Dr. GALABIN exhibited two specimens of Uteri removed per vaginam for supposed malignancy. Under the microscope the appearances of one were those of ulcerative endometritis, the other was a case of round-celled sarcoma. The former patient recovered, but the latter died.

Adjourned discussion of Dr. Griffith's paper on Tubo-ovarian Cysts.—Mr. DORAN considered that Dr. Griffith's definition of a tubo-ovarian cyst was sound enough for practical purposes. The term "ovarian cyst" was, however, vague, as the nature of cystic disease of the ovary, other than that kind for which ovariotomy was performed, was very uncertain. In any form of obstruction of the tube, such as that which led to cystic dilatation, the uterine end was probably closed by swelling of the mucous membrane. Mr. Doran then exhibited several specimens. The Fallopian tube was very rarely diseased in true cystic tumour of the ovary. In one specimen, where the tube was inflamed and bound down to the surface of the cyst, the ostium was patent and the fimbriæ unaffected. Another series of specimens showed the most frequent origin of tubo-ovarian cysts —namely, chronic inflammation of the uterine appendages, whereby the tube and ovary became bound together, and ultimately underwent cystic degeneration, their dilated cavities communicating by the same process as was observed in the septa of multilocular cysts. Many observers made out that the obstructed ostium opened again into the cavity of the cystic degenerated ovary, but that was exceptional. The congenital form was very rare; but Paltauf's case, recently reported in the *Archiv für Gynækologie*, was probably of this kind. A woman died of peritonitis after attempted abortion; a fœtal cyst was found behind the uterus, which communicated with the dilated Fallopian tube, so that there was a free channel from the uterine cavity found through the tubes and cyst back into the [illegible]. The parenchyma of the ovaries was flattened, but contained healthy follicles. This condition could hardly have been caused by disease; it was a congenital malformation; but Dr. Paltauf's memoir required study. Congenital tubo-ovarian cysts, and that kind where the fimbriæ [illegible] to a cyst on the surface of the ovary, were exceptional; as a rule, a tubo-ovarian cyst was one of the forms of [illegible] caused by chronic disease of the appendages. Mr. Doran remarked that whatever might be the true [illegible] of the formation of so-called tubo-ovarian cysts, which [illegible] beginning in the Fallopian tube or the [illegible] these structures were apt to become [illegible] when they were in contact, and he believed [illegible] of such union was frequently the ovary.—[illegible] explained.

[illegible] *Pregnancy and Labour.*—[illegible] two cases of the disease. One [illegible] persistent, and in it there were eleven pregnancies. He narrated other two cases in his own practice, and in one of these there were [illegible] nancies during the currency of the disease. Diminution the quantity of urea secreted appears to be of importance in it. Similar cases of greatly reduced secretion of urea, with feelings of weakness and sickness, Dr. Matthews Duncan has observed in women not pregnant or recently delivered.

The Mechanism of the Third Stage of Labour.—Dr. FRANCIS H. CHAMPNEYS dealt with Part 4 of this subject under the heading "Some Causes of Retention of the Membranes." Having referred to the description of the process given in a former paper, the author showed that the "plane of least resistance" for separation of the membranes is in the decidua, generally in the ampullary layer. Any change which renders this more tough, or which renders any other layer more friable, will alter this "plane of least resistance." Thus, undue friability of the chorion, or less firm adhesion between chorion and amnion than between the layers of the decidua, will determine a separation of the chorion and amnion. The early separation of the lower pole of the ovum tends to guard against a common defect—viz., failure of separation (retention) of the membranes round the os internum. Rupture of the membranes at the proper time is an essential part of the proper mechanism. The proper time is, in nature, when the os is about three to three and a half inches in diameter, and has a projection of three-quarters to one inch. Premature rupture will prejudice the separation of the lower pole of the ovum. Too late rupture tends to produce prolapse of the bag, which is usually accompanied by giving way of the chorion and advance of the amnion alone. Undue or relatively undue toughness and elasticity of the amnion are equivalent to a tardy escape of the waters. As regards the removal of the membranes by traction of the descending placenta, the author remarked that the membranes as a whole owe their tenacity principally to the amnion; the adhesion of the amnion to the chorion is no doubt one of the safeguards against retention of the chorion. Thus, any disorder of the first process of the mechanism tending to separate the two ovuline membranes predisposes to retention of the chorion. An analysis of ninety cases bearing on the matter was given. The conclusions were: 1. That the mechanism of the detachment and expulsion of the membranes is a complex act in three stages. 2. Timely rupture of the bag of membranes is an essential part of the proper mechanism, and too early or too late rupture alike predispose to retention of the chorion. 3. Disorder of any of the three stages in the mechanism tends to prejudice the whole process. 4. Among allied conditions may be mentioned too early or too late rupture of the membranes, prolapse of the bag of membranes, prolapse of the membranes (amnion) after delivery beyond the vulva; separation of the membranes found on examination of the placenta; retention of a ring of membranes round the lower pole of the uterus; retention of the whole chorion. The practical conclusions were: 1. The membranes should generally be preserved till the os is fully dilated. 2. After this they are not only (in ordinary cases) useless, but they—that is, the persistence of the amnion—favour the retention of the membranes. 3. They should, therefore, be ruptured when the os is fully dilated. 4. In vertex cases, if the head has settled over the os uteri, the advance of a smooth, sausage-shaped protrusion of membrane points to advance of the amnion alone, which favours retention of the chorion. 5. Separation of two membranes not only points to adhesion of the chorion, but renders its subsequent removal more difficult. 6. This axiom may be formulated: "When the membranes advance low in a vertex case, look out for retention of the chorion."

The Relation between the Implantation of the Placenta and the Insertion of the Cord.—Dr. Champneys also submitted a note on this subject.—In his work, "Accouchemens Laborieux" (suite p. 110, *et seq.*), Levret makes the following statements:—That the insertion of the umbilical cord into the placenta varies as the insertion of the placenta on the uterine wall. If the placenta is central, the cord is centrally inserted; if the placenta is excentrically planted, the cord is inserted nearer to the lower edge; if the placenta approaches the lower uterine orifice, the cord is inserted to its edge ("battledore placenta"), and, indeed, to its lower edge. This is given without corroborative facts, as an *ipse dixit* of Levret; but it still survives though more than 130 years old, and has even (at least in part) been endorsed by the writers of some of our most recent books. Under these

Digitized by Google

circumstances the author thought it worth while to put the matter to the test. If it prove true, it is so remarkable a fact that it should be accounted for; if it be false, the sooner it is relegated to the proper place for unauthorised statements and *ipse dixits* the better. The following analysis of 188 cases treated in the General Lying-in Hospital is offered as a solution of the question. The patients number 188, but as one of them bore twins the number of placentæ is 189. The table contains the class of insertion of the cord, states whether its insertion was up or down, and gives the measures from which this is derived. The next two columns give the position of the placenta in the uterus; the last two columns give the position of the insertion of the cord in the uterus. It will be seen that there is no order or proportion apparent in any of these relations. As regards the position of the cord:—

Insertion of cord.	Direction of point of insertion.							
	Up.		Down.		Midway.		Not noted.	
Central ...	17	...	18	...	17	...	4	
Lateral ...	46	...	54	...	16	...	1	
Marginal	7	...	5	...	—	...	—	
Velamentous	1	...	1	...	2	...	—	
	71	...	78	...	35	...	5	
Total		...	...	189				

Levret's dictum, therefore, has no foundation in fact.

The PRESIDENT, in opening the discussion on Dr. Champneys' series of valuable papers, did not think that late rupture need cause retention of the membranes.—Dr. MATTHEWS DUNCAN valued highly this series of papers. He would have preferred protrusion or expression of the membranes to prolapse, as bearing a truer meaning. He was not inclined to adopt any rule of interference by rupturing the membranes at a certain stage of the dilatation of the external os, regarding all kinds of interference as undesirable, except when distinctly called for. He did not regard the site of rupture of the membranes as a sufficient basis for a statement of the height of the placental insertion on the uterine wall. He thought Dr. Champneys had disproved Levret's dictum as to insertion of the cord.—Dr. CHAMPNEYS, in reply, said that when he spoke of late rupture of the bag of membranes, he did not refer so much to time, but to a certain point in the process, that after the bag was hemispherical its dilating power ceased, and it could not advance without rupture of the chorion, and if this took place the amnion advanced alone and peeled itself off the chorion, which then was often left behind. He used the term "prolapse" of the bag as an exact translation of the technical German for this occurrence, and to avoid mistake had placed the term in brackets in the paper. He thought the method adopted for determining the seat of the placenta was the best we possessed, and that the errors in a large number of cases would not be sufficient to invalidate general conclusions.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

AT a meeting of the members of this society on June 7th, after the report of the Council had been adopted,

Professor MACALISTER read a paper on Some Common Errors in Descriptions of the Brachialis Anticus Muscle. This muscle was chosen, not because the descriptions of it were more inaccurate than those of the other muscles, but because it was convenient for the purpose in view—namely, to exemplify the general incorrectness of anatomical descriptions. The paper concluded with a correct account of this muscle; and Professor Macalister said he proposed to consider others in a like manner.—Mr. STONHAM drew attention to the appearance of the tendon of the brachialis anticus, and said it was of surgical importance.—Professor THANE said text-books were likely to benefit by this mode of criticism, and asked questions, to which Professor Macalister replied.

Dr. BROOKS of Dublin then read a paper on the Short Connexion Muscles of the Pollux and Hallux of Anthropoid Apes (see next column), and in the discussion which followed Professors Macalister and Thorne took part.

Mr. SUTTON then read a paper entitled a "Critical Study in Cranial Morphology." It was claimed that upon anatomical, morphological, and embryological grounds the dura mater ought to be considered the original skull wall, and that therefore the ganglia of the fifth, facial, and eighth nerves were extra-cranial. The relations of various nerves to the subcranial arches were next reviewed.—Mr. LOCKWOOD said he had found that the facial nerve and internal carotid artery had the relations to the skull which Mr. Sutton described, and, although he had not seen more than two ossific centres in the malar bone, nor three which had been described in the lower jaw, yet he thought there was much to be said for the first part of Mr. Sutton's contention.—Professor THANE also doubted the existence of more than two centres in the malar bone.—Professor MACALISTER could not find as many centres in the lower jaw as Mr. Sutton described.—In reply, Mr. SUTTON promised to bring specimens to the next meeting.

Mr. BERRY then read a paper on a ligament which, on either side, suspended the thyroid gland to the cricoid cartilage.—Professor HUMPHRY agreed that Mr. Berry's specimen showed a pair of strong ligaments.

The following specimens were shown:—Mr. Rickman J. Godlee and Mr. C. Stonham: Casts of Bronchi. Mr. Jas. Berry: Suspensory Ligament of Thyroid Gland. Dr. W. J. Collins: Abnormal Aortic Arch. Professor Curnow: Subclavian Artery passing in front of Scalenus Anticus. Mr. Lockwood: Cases for Mounting Frozen Sections.

ACADEMY OF MEDICINE IN IRELAND.

Dissection of Plantar Arch from Dorsal Aspect.—Varieties in Origin of Phrenic Nerve.—Anthropoid Apes.

AT a meeting of the Subsection of Anatomy and Physiology, held on May 5th,

Dr. BROOKS showed a dissection of the Plantar Arch from the Dorsal Aspect of the Foot. This dissection was performed by removing the three middle metatarsal bones from above.

Dr. BROOKS read a paper on the Varieties in the Mode of Origin of the Phrenic Nerve, with some notes on nerve variations in the superior extremity.

Dr. BROOKS also read a paper on the Short Muscles of the Pollux and Hallux of Anthropoid Apes, with special reference to the Opponens Hallucis. The author remarked that the number of distinguished anatomists who have written on the structure of the anthropoid apes might make this paper appear a work of supererogation, were it not that very material differences occurred in their writings, more especially in regard to the small groups of muscles which he proposed to describe. The labours of von Bischoff, D. J. Cunningham, and others had shown that the names usually applied to the thenar muscles of the human hand conveyed an altogether erroneous idea of their morphology; he therefore adopted the following names for the short muscles of the thumb: *abductor* and *opponens pollicis*, as ordinarily described; *flexor brevis pollicis*, consisting of a radial and an ulnar head—*radial head*, as described by Gray and Ellis; *ulnar head* = the *interosseus volaris primus* of Henle—a small deeply-placed muscle arising from the base of the thumb-metacarpal bone and inserted into the sesamoid bone, at the ulnar side of the metacarpo-phalangeal articulation of the thumb; *adductor pollicis*, consisting of three parts—(*a*) a *slip* attached to the radial sesamoid bone of the thumb (regarded by Quain as part of the radial head of the flexor brevis pollicis); (*b*) *adductor obliquus* = the so-called *inner head of the flexor brevis*; and (*c*) *adductor transversus* = *adductor pollicis*. After describing the short thumb muscles of the chimpanzee, orang, and gibbon in detail, the author concluded that the pollicial muscles of the gibbon differ from man—(1) in the proximal position of the adductor; (2) in the part-insertion of the adductor into the metacarpal bone of the thumb; (3) in the prolongation of two of the short muscles (adductor and flexor brevis) to the ungual phalanx; and (4) in the greater relative development and more palmar position of the true ulnar head of the flexor brevis. The orang differs from man chiefly in its very feeble opponens. The opponens is very human in its character in the other two apes. The ulnar head of the flexor brevis is less developed in the orang than in the gibbon, but is still large in comparison with the interosseus primus volaris of man, and much more palmar in position than the latter muscle. In the chimpanzee all the thumb muscles are excessively human, but the ulnar head of the flexor brevis has suffered a still further reduction,

Digitized by Google

than in man, being here reduced to a fibrous rudiment. After referring to the works of Vrolik, von Bischoff, Duvernoy, Huxley, Church, Champneys, Hartmann, and others, the author proceeded to describe the short muscles of the hallux, in which the principal interest centred in the opponens hallucis. He had only found an opponens hallucis, derived from the tibial head of the flexor brevis hallucis, and therefore homologous to the opponens pollicis, in the orang; it was absent in the chimpanzee and gibbon (he had not had an opportunity of examining the gorilla). In all three anthropoids, however, he had found some fibres of the abductor hallucis inserted into the metatarsal bone of the hallux, and these would come under Professor D. J. Cunningham's definition of an opponens—viz., "any intrinsic muscle of the foot which is inserted into the shaft of a metatarsal bone" (Zoology of the *Challenger*, vol. xvi., p. 137). The opponens hallucis described by Hartmann in the gorilla, chimpanzee, and gibbon is probably of this nature, as in the gibbon he describes an opponens "to which a large fan-shaped adductor is attached.

Malformation of the Shoulder Joint.—Capillary Transudation.—Fracture of the Skull.

At a meeting of the Pathological Section held on May 13th, Dr. E. H. BENNETT exhibited a specimen of Malformation of the Shoulder Joint. It was a form of malformation or disease that he had never seen before, and the only way in which he could read it was that it was not congenital, nor the result of a fracture or dislocation, but a condition brought on by the action of a burn, the cicatrices of which existed on the limb and near the joint. The limb belonged to a slender man of middle age. It was dissected in the School of Physic, and had previously attracted attention in consequence of deformities that appeared in the fingers, the result of burn contractions. The little finger was burned towards the ulnar side, and its extremity had been lost; and the finger next it had suffered similarly, but to a lesser degree. The cicatrices were not such as to produce large webs or great deformities, but the end of one finger was completely destroyed, and there were marks upon the limb of burning of the skin. These were the only circumstances that threw light on the question of the cause of the deformity. It was noticed before the dissection was made that the shoulder joint, although not completely fixed, was limited in its range of motion. There was nothing abnormal in the muscles, except that at those of the dorsum scapulæ were to some extent wasted; all the muscles were otherwise good. The condition of the shoulder joint was curious. On clearing away the soft parts on the outside of the joint, Dr. Bennett found what at first sight appeared to be the head of the humerus directly underneath the muscles, without any capsule, while the upper part of the humerus was distorted and bent. There was no disease of the scapula or glenoid cavity; on the contrary, everything there was normal. The length of the fibrous capsule was very small. The appearance as of a head of the humerus which the specimen presented, looking at it from the outer side, was fallacious. On turning the specimen, it was seen that the head of the humerus was half buried in an ossified capsule, while the remaining half of the capsule was free, soft, and flexible, and received the attachments of the capsular muscles normally on the axillary side. There were no deep cicatrices involving the muscles, and the tendons and joint had been in no way affected except by the skin contraction. It was hard to account for this condition of the capsule and the extraordinary limitation of the ossification of it to the outer side. On the inside the cartilage of the joint was perfectly normal. He had not made any section through it, because he did not think it would reveal much. The head of the bone was greatly distorted in position. He did not think there had been any fracture of the bone, but believed that the flexion of the upper part of the bone and distortion of the head of it had been produced by the limited range of movement resulting from the superficial cicatrices.

Mr. STORY exhibited an apparatus intended to illustrate an experiment of Körner upon Capillary Transudation. In reply to questions, Mr. Story said that the experiment of Körner was published in 1873; but in spite of the vast amount of work that had since been done in connexion with glaucoma, no one seemed to have noticed its importance till Bürabacher and Czermak had taken up the subject in their paper in the December (1886) number of Graefe's Archives.

Dr. HEUSTON exhibited the Skull and Brain of a ge man, aged sixty, who had fallen from a window in flagged area on his head, a distance of twelve feet. Aft the accident he presented no evidence of serious lesion for five days, when symptoms of cerebral irritation began, eventuating in hemiplegia of the left side of the body on the tenth day, when he died from paralysis of the muscles of respiration. The skull presented a fracture occupying the posterior portion of the right parietal bone, which included a somewhat quadrilateral area, the enclosed portion of bone being further broken into three portions, the upper of which was depressed, while the two lower were elevated at their junction. From the posterior-inferior angle of this fracture a fissure extended through the masto-occipital and petro-occipital sutures to the jugular foramen, from which a fracture extended into the foramen magnum posterior to the occipital condyle. An extensive clot was also found occupying the position of the fracture, and also filling the posterior fossa of the skull between the dura mater and the bone; the dura mater in this situation presented a laceration an inch in length. The right cerebral hemisphere presented a laceration at the junction of the occipital with the temporo-sphenoidal lobe, extending obliquely upwards and backwards for an inch and a quarter, and being half an inch in breadth. The inferior aspect of the right lobe of the cerebellum showed a laceration occupying the biventral lobe half an inch in length.

Reviews and Notices of Books.

Leçons sur les Auto-intoxications dans les Maladies. Par Ch. BOUCHARD. Recueillies et publiées par le Dr. P. LE GENDRE. Paris: F. Savy. 1887.

PROFESSOR BOUCHARD has made the subject dealt with in this course of lectures delivered at the Paris Faculty of Medicine his own, and there is no gainsaying that it is a subject abounding in interest and novelty, and at the same time of very great importance. It constitutes an attempt to unravel the hidden processes of disease by the demonstration that a large proportion of the symptoms of disease depends upon the operation of materials obnoxious to normal nutrition, whether such poisons be introduced from without or be the accumulated products of metabolism retained within the organism by failure of the eliminatory organs.

The key to the last-named source of "intoxication" is to be found in the composition of the urine, which has been studied by Professor Bouchard from the point of view of its "toxicity," with so much care and elaboration that he is enabled to give numerical expression to the degree of toxicity possessed by this product of excretion. It is singular to read these values in terms of the amount of living animal matter destroyed by a given quantity of urine, but it is not easy to detect any fallacy in the argument, whilst it furnishes us with a new point in the estimation of toxic action. The study of the toxicity of urine in general, and a comparison of the degrees of toxicity at various times and in various conditions, is followed up by an analysis of the constituents concerned in these effects. Hitherto, with one or two exceptions, it has not been found possible to isolate these constituents, which, having different physiological actions, must be presumed to differ in chemical composition. Most of them are organic but not alkaloidal; some are soluble in water, others in alcohol—urea is one and potash another; whilst a third resides in the colouring matters of the urine; but more than this it is not possible to affirm. By physiological analysis it is, however, possible to infer the existence of at least seven different agents having toxic powers in the urine. There is a diuretic substance — this is probably urea—which is characterised as the most powerful of known diuretics. Secondly, there is a narcotic, and thirdly, a sialogenic substance, neither of which has been isolated chemically. Then there are two products one organic the other mineral, which induce convulsions in the animal acted upon by them; there is no doubt that the mineral substance

Digitized by Google

having this action is potash. Then there is a body that is signalised by its powerful myotic action, causing marked contraction of the pupil; this may be found in the colouring matter. Lastly, there is an agent that depresses bodily temperature. The phenomena of uræmia—of which the various theories propounded are in turn discussed by the author—are well explained by the action of some or all of these toxic agents retained in the blood through the failure of the kidneys to eliminate them, and the predominance of one class of symptoms over another may be due to the relative preponderance of one or other of these poisonous constituents.

The toxicity of urine being established, the next step in this physiological inquiry is to determine the sources whence the urine receives the several toxic agents. The blood, the tissues, the intestinal canal, the bile, are therefore each studied in this relation, with experimental proof of the facts advanced. The sum of all these researches is to place first in the rank of toxic animal products mineral substances, especially potash, whether derived from food or from tissue metabolism; next in importance come the products of intestinal putrefaction, ammonia being among the chief; and thirdly, the organic products of metabolism, with which may also be classed the small quantity of bile that is absorbed from the surface of the intestine. Although of necessity these materials all pass through the blood, yet in health the blood has a feeble toxicity as compared with the urine, in which these products accumulate prior to their discharge from the body. It is shown that the urine may be deprived of some of its toxicity by arresting intestinal putrefaction—in other words, by intestinal antisepsis; for which purpose Professor Bouchard assigns most value to the use of charcoal and of naphthalin; and accordingly we find attention to such measures urged in the treatment of uræmia, to which he devotes other lectures. Indeed the subject of auto-intoxication through the intestines, whether in constipation or ileus, is one which cannot fail to have been present in the mind of every physician; but the extension of the same idea to gastric dilatation is more novel, and in some respects very startling. It is, however, a subject which Professor Bouchard deals with in an exhaustive manner; so that, if he does not convince, he at any rate suggests ideas which give a wider meaning to the term dyspepsia, and to the results that may accrue from it. The catalogue of maladies attributable, on his reasoning, to dilatation of the stomach through the absorption of poisons into the blood is a lengthy one. It requires a considerable effort to accept the notion that albuminuria, nodular rheumatism, osteomalacia, certain skin diseases, and many other affections have an etiology in common in derangement of the normal processes of digestion. At the same time it must be confessed that it is just on this subject of etiology that we are most ignorant, and any reasonable hypothesis which can be shown to be based on facts is not to be lightly set aside. Professor Bouchard has maintained his thesis in spite of opposition and ridicule, and is confident that time will show that his conclusions are just.

The doctrine of intestinal auto-intoxication is further advanced in explanation of some of the phenomena of typhoid fever, where the value of intestinal antisepsis is urged, combined with general antisepsis—i.e., the administration of drugs directed against the typhoid virus, the use of graduated baths, and a regulated diet. From this subject the lectures pass to the discussion of the toxicity of bile and the effects of retention of bile on the system. It is shown that were it not for the elimination of the colouring matters by the urine and their fixation in the tissues, jaundice would speedily have a fatal issue, for the biliary colouring matter is highly toxic. The bile salts also act deleteriously by destroying muscular tissue and blood corpuscles, thus setting free mineral and organic matters, notably potash, the poisonous effects of which have been demonstrated. In malignant jaundice these toxic agents exert their full power, because, owing to the liver itself being profoundly deranged, there is no formation of urea, and the kidneys are deprived therefore of the influence of their natural diuretic, and the elimination of the biliary poisons is thus prevented. Diabetes and cholera are also discussed from the same point of view, and it is shown that in the latter we have not only to contend against the primary action of the choleraic virus, but also with uræmia.

We can warmly commend these lectures to careful study. They cover, as we have intimated comparatively new ground, and they do this in a manner at once so clear and detailed as to carry the reader with them. But apart from this, they suggest lines of thought in the problems of pathogeny which are well worth maturely considering and putting to the test of observation.

Abdominal Surgery. By J. GREIG SMITH, M.A., F.R.S.E., Surgeon to the Bristol Royal Infirmary, late Examiner in Surgery, University of Aberdeen. London: J. & A. Churchill. 1887.

MR. GREIG SMITH'S book will undoubtedly be useful. It is a careful attempt to describe all the various operations which are generally grouped together as abdominal, and by reference to its pages much time that would otherwise have to be devoted to looking up scattered articles will be saved. The book opens with a chapter on the Diagnosis of Abdominal Tumours, which is followed by a description of the general conduct of abdominal operations and of the after-treatment of the patients. In this chapter the influence of Mr. Lawson Tait's teaching upon the author is very evident. Then follow several chapters devoted to the special operations upon individual abdominal organs. Among these the urinary bladder is not included. We can quite appreciate the reasons which led Mr. Greig Smith not to describe supra-pubic puncture or incision of the bladder as an "abdominal operation," especially as they are extra-peritoneal. But as the suture of a rupture of the peritoneal aspect of the bladder promises to be the best mode of treating this injury, and as it is so similar in its *technik* to enterorraphy we should suggest to Mr. Greig Smith to include it in any future editions of the work.

The whole work is clearly written and carefully done. Authorities have been diligently consulted, and so far as we have noticed all descriptions are accurate. Divergencies of opinion are fairly given, and arguments are advanced with ability. The author has striven to portray the present position of abdominal surgery, and in the form analogous to a text-book, rather than to draw from his own experiences only for his facts. We consider his book a success and anticipate for it a favourable reception.

ST. JOHN AMBULANCE ASSOCIATION, SCARBOROUGH.—During the past winter two detached classes of first aid to the injured have been held, one for men and one for women. The lectures were fairly well attended, the joint classes numbering 34; of this number 26 presented themselves for examination, all of whom received certificates. Lectures were also given at Gantom and were very well attended, each class numbering 30. Thirty-eight candidates from the two classes presented themselves for examination, and 32 received certificates. A single lecture on the restoration of the apparently drowned was also given at St. Thomas' schoolroom to the fisherman, and was well attended. The classes were instructed by Mr. W. H. Beverley, L.R.C.P. Lond., &c. of Scarborough, and examined by Mr. E. Atkinson, F.L.S., &c., of Leeds.

TRICHINOSIS IN CARTAGENA.—*El Siglo Medico* states that there have been a number of cases of trichinosis in Cartagena, and that up to the present time no less than twenty-three persons have died of the disease.

New Inventions.

NEW MEDICAL BATTERY, ILLUMINATORS, AND CAUTERY.

THE battery depicted below appears to be likely to obviate many of the objections hitherto raised to the use of electricity in medicine on account of its alleged "unmanageableness." Its primary object is to develop the electric light in many convenient forms; but it can also, with but little modification, be applied for galvanisation, faradisation, and cauterisation. The battery (Fig. 1) consists of four improved Leclanché's cells, the elements being zinc and carbon, with some oxide of manganese, excited by dilute sal ammoniac; they are connected together as single cells, with power of selecting any number; they are enclosed in a neat box, measuring 7 in. high, 11 in. long, and 6½ in. deep, and having a drawer for the conducting wires and various appliances required. Metal sockets, marked N and P, receive the ends of the wires, which are sufficiently long to admit of the battery being placed at a convenient distance, and the number of cells employed is controlled by a selecting

FIG. 1.

lever on the left of the surface plate, while more accurate graduations are established by moving a second lever acting on a resistance coil more or less to the right. By the provision of suitable rheophores, this battery can be used, so far as its range extends, for galvanisation in the same manner as ordinary galvanic batteries, its [illegible] electro-motive force being equivalent to about eight [illegible]'s constant current battery. By the addition [illegible] with adjustments, faradisation also can be [illegible] also a small platinum loop with switch can [illegible] ught to a white heat, so as to be readily [illegible] minute cauterisation. The conductors are of [illegible] wire, carefully insulated with silk, and [illegible] ience through the greater part of their [illegible] s to be used with the above are small [illegible], composed of minute glass beads, con- [illegible] of carbon connected with platinum wires [illegible] r along the shafts of the various instru- [illegible] nal extremity, where they terminate in [illegible] the reception of the conducting wires [illegible] ery. These instruments are for the [illegible] or three patterns, and each is furnished [illegible] switch for cutting off or admitting [illegible]

the current at will. The first (Fig. 2) is the lamp in simplest form, and consists of a shaft of celluloid, 8 in. long, covered at its further extremity with the small incandescent lamp referred to, half sunk in a cup-shaped receptacle which protects the user's eyes from undue tension, while at its hither end is a small spring connector not shown in the drawing, which when pressed by the thumb completes the circuit and displays the light. This instrument serves for examinations of the ear and nose, with or without a speculum, and is adapted for the use of dental surgeons. The second is used for examining the vagina or rectum through a tubular speculum of any available size. In this the lamp, which is similar in construction to the one just described, but much more slender in the shaft, is attached to an expanding ring which adapts itself readily to any size of speculum, clinging slightly to it, so as not to be displaced by accidental movements. The lamp and ring are slid along the speculum to its extremity, so that its rays are concentrated precisely where they are required, and the mouth of the speculum is not blocked up by clumsy apparatus which obstructs the observer's view and impedes the employment of cautery or other instrument. The third pattern (Fig. 3) is intended to be used chiefly for the

FIG. 2.

FIG. 3.

examination of the palate or larynx, though it will also serve for inspecting the vagina by depressing it. It consists of a celluloid spatula, bearing a lamp at its further end half sunk in a cavity of its substance, so as to present only the most trifling elevation above its surface. The wires of this lamp are conducted to the commutator in a deep closed groove along the edges of the spatula, and it will be seen that the instrument can be used as a tongue depressor as well as an illuminator. The heat evolved by these lamps is inappreciable. Mr. T. Partridge Salt, Corporation-street, Birmingham, is the inventor and manufacturer of these instruments.

NURSERY DIAPERS.

WE have received from Messrs. Barton and Co., Towel Manufacturers, Congleton, some specimens of Turkish nursery napkins for children's use. They appear to us to be well adapted for the purpose in view, as they are soft and absorbent, and easily cleaned by being soaked, which all napkins should be, in cold *soft* water. The napkins in question are made in two convenient sizes—23 in. by 23 in. and 27 in. by 27 in.

THE LANCET.

LONDON: SATURDAY, JULY 16, 1887.

IT is too soon to state with exact precision the sum of the Hospital Sunday Collection for 1887; but it is possible to guess that it will not very materially differ from that of last year. It will not be large enough to satisfy the great wants of the hospitals, or the large views of those who maintain that the united churches of London should be able easily to raise £100,000. But it will still be a large collection, and will represent much good will on the part of the religious communities of the metropolis. The exceptional nature of the year, as the Jubilee of Her Majesty's great reign, may yet tell in favour of the great institutions in which the sick find help and refuge in the day of their calamities. It may well be that some generous hearts are still exercised in devising liberal things that shall make the year more glorious still, and bring joy to the hearts of anxious treasurers; but so far as at present appears there will be no conspicuous increase in the church collections, and there may possibly be a slight falling off. We will not deny that we feel some regret at this fact. We have no sympathy with certain of our contemporaries who, some of them claiming to speak in the name of charity and philanthropy, seem to find a certain satisfaction in the limitations of this collection, and who speak as if the utter failure of the institution would be rather a gratification to them than otherwise. These are strange sentiments to find expression in organs which are supposed to appeal to the benevolence of the public. One such contemporary labours to explain if not to justify such sentiments. Amongst other reasons he adduces a very far-fetched one, "the absolute delay which some persons suffer who require the immediate relief afforded by surgical appliances." Whatever the shortcomings of the Hospital Sunday Fund, and, like all other human institutions, it has its faults, it has had much praise for the promptitude with which, so long as its funds last, it supplies surgical apparatus, and many a person wanting an artificial limb, or an elastic stocking, or a surgical boot has had occasion to bless the Hospital Sunday Fund, or rather the minister of the church or chapel who contributed to it. Another excuse for criticising the Hospital Sunday Fund is almost equally invalid—viz., the views of one or two members of the Council as to the action, or rather inaction, of certain hospitals in reference to the local meetings for promoting the Hospital Sunday Fund. To found on them any argument for the decline of the fund is to build on a very infirm basis. The rules of the fund are the work, not of the Council, but of the constituents in annual meeting assembled in December. It will be time enough when the constituents alter the rules to object to them. Meantime, they are admittedly fair, and give the Council no authority to interfere in the internal administration of hospitals. We have read a statement by Mr. JOHN BIDDULPH MARTIN, treasurer of the Charing-cross Hospital—one of the hospitals complained of by Sir EDMUND CURRIE for want of interest in the local meetings. Mr. MARTIN, on the strength of very imperfect newspaper reports of what happened at the meeting in May, speaks of the "Committee" (Council) "endorsing and publishing the opinions of its honorary secretary, and thus doing injustice to the hospital." Mr. MARTIN expresses full appreciation of the benefits hitherto derived from the Hospital Sunday Fund. We therefore feel sure that on reflection he will see that he is at least premature in the charge which he brings against the Council. Sir EDMUND CURRIE is one of the truest and most hardworking friends of hospitals and of the Hospital Sunday Fund; still Mr. MARTIN will find at the December meeting that his views will be duly and fairly considered.

The collection for 1887 will, we repeat, be not materially different from that of 1886, and the Jubilee so far has not added to the fund. It may do so even yet. But let us not give way to too much disappointment if it does not. The Jubilee calls have been legion. And we may easily expect too much of the churches. We forget that they have great expenses to bear, that not a few of them have private charities of their own to support, and that their members still are the chief private contributors to our great hospitals. When we compare the Hospital Sunday Fund of London and that of other large towns, to the discredit of London, we must not forget that London charities largely receive the blind and the deaf, the halt and the sick, of the provinces. London gets well blamed for her luxury, and we are not disposed to say she gets too much blamed. But we can easily see that many London congregations cannot well do more than they do for the fund. Many of them have a struggle to support their ministers and the ordinances of religion, and yet make a noble effort to help the hospitals. All honour to them. So far as we yet know, the result will show that in most congregations there is an increase. Even Canon Fleming contrived to exceed his handsome collection of 1886 by £17, and the congregation of St. Paul's, Knightsbridge, theirs by £119. In Christ Church, Lancaster-gate, there is the creditable increase of £236 over that of last year. In Mr. Spurgeon's Tabernacle there is an increase of £50, in the Temple Church of £64, in Union Chapel of over £40. There is an increase in more churches than those in which there is a decrease. But we may here remark that although St. Jude's, South Kensington, does not quite reach its last year's total, its vicar, the Rev. Dr. Forrest, is to be congratulated that the falling off is merely nominal, and that it still maintains a foremost position. With such facts, and with all the distractions and expenses of this London season, it is clear that the fund has lost nothing of the goodwill of the religious community, even if we have to recognise that there are limitations to the amount of support to hospitals to be expected from this quarter.

THE invalid is obviously under restrictions regarding both the *when* and the *where* of his holiday from which the ordinary holiday seeker is free. Exigencies of health may compel a holiday at any season, and render imperative a careful choice of locality to meet the special needs of each individual case. The subject being, however, much too wide for proper treatment within the short space of a single article, we shall select for consideration one case only, and that perhaps the commonest of all—namely, the case of the individual who, apart from serious organic disease, finds

Digitized by Google

himself somewhat out of health, and desires to gain the maximum of advantage by his annual holiday of a month. Such persons may be dyspeptic or "nervous," complaints of want of appetite and disordered sleep being among the most frequent, or they may have some slight throat affection, or complain simply of "weakness," and unfitness for the ordinary routine of life. It is in such cases, in which experience usually proves the impotence of drugs, that change of air, scene, and habit works some of its most remarkable and beneficent results.

Some practitioners, impressed with the great benefit accruing from change of air, are disposed to regard the change itself as the one essential point, and exercise little care in repect of the locality to which their patients repair. In some cases this negligence may be harmless, but in others it is fruitful in mischief. The climates of sea, mountain, and plain differ too profoundly in their meteorological features and physiological action to be recommended indifferently, and a patient who benefits by one of these types of climate may be seriously injured by another. Take the case of insomnia, for example. In the milder cases any change may do good, but in the severer cases sea air and mountain air are often alike injurious. A quiet sheltered inland resort suits such cases best in the first instance, and as convalescence proceeds this may be advantageously exchanged for some more bracing resort, such as Buxton or Harrogate. We know of a patient who suffered from severe insomnia, and was advised to try Llandudno, where the stimulating sea air greatly aggravated his trouble. On removing to the quiet valley of Llanberis, under the shelter of Snowdon, he obtained immediate relief. This fact is the more worth bearing in mind, as in thoroughly healthy people sea air usually conduces to sound sleep.

As a general rule, neurotic patients of all kinds should be prohibited from resorting either to the seaside or to high elevations. Their symptoms are commonly aggravated by all stimulating climatic conditions, and they benefit most by sheltered inland resorts, either of the plain or some mountain valley. The sufferer from neuralgia comes under this rule. At the favourite health stations of the Riviera—Cannes, Nice, Mentone, San Remo, &c.,—it is a common experience to find neuralgia much aggravated on arrival, but speedily alleviated by removal inland.

The case of the dyspeptic deserves the most careful consideration both from its frequency and from the marked benefit which so often accrues from a well-planned holiday. Here, again, a distinction must be drawn between the [illegible] and the graver cases. The former may benefit by almost any change; the latter will be injured unless the change be wisely ordered. In serious cases of dyspepsia, especially if there be hepatic derangement, the seaside is [illegible] as a general rule, the best change being [illegible] to such resorts as Ilkley or Crieff, where the air is [illegible] without being unduly stimulating. Dr. CLIFFORD [illegible], in his well-known Gulstonian lectures upon [illegible], states truly that a week or two of bracing [illegible] will restore to its normal condition a tongue [illegible] drugs—soda, gentian, podophyllin, and [illegible] have failed to clean. Dr. ALLBUTT draws [illegible] conclusion that such cases are often pure [illegible]. We must here, however, content ourselves with pointing out the great benefit derived from inland moderate elevation in cases which, for the present, we must still describe as "dyspeptic."

We have dwelt upon the disadvantages of sea air in certain cases, and we must strongly protest against the too common practice of the profession in ordering patients indiscriminately to the seaside; but the cases are not few, or unimportant where sea air is one of the most potent remedies within our reach. It is excellent in struma, in rickets, in many cases of early consumption. It is an admirable tonic and restorative to many persons who are simply overworked and "out of tone." It is often the most efficient means of completing convalescence after acute disease, but in this case great care must be taken not to recommend it at too early a stage. Sea air is for *late*, not for *early*, convalescence. On the other hand, as already pointed out, sea air is often hurtful to neurotic and dyspeptic cases. It is also frequently injurious to sufferers from cutaneous maladies. We may give, for example, the case of a patient who for ten or twelve years has suffered intermittently from dry eczema of the fingers. The disease is kept perfectly in check by occasional doses of arsenic so long as the patient resides inland, but on the various occasions on which she has removed to the seaside for the sake of her family, the disease has never failed to make its reappearance. There is one fact in reference to sea air about which there can be little question, and which no doubt largely accounts for its popularity—namely, that while calling for careful discrimination in all cases of disease, it may be freely recommended to most persons in average health, with the assurance that it will probably make those better who are already well.

Mountain air finds one of its most important applications in the case of fagged brain-workers who retain a fair amount of energy and are free from much nervous irritability. To such it often acts as an excellent tonic and hypnotic, stimulating appetite and digestion, luring back sleep, and fulfilling the function of perfect remedy in a species of ailment which is particularly unresponsive to medicinal agents. The point of discrimination in such cases is the presence or absence of nervous irritability, its presence being a bar to the recommendation of high mountain air, and calling rather for some quiet inland resort of moderate or low elevation.

A type of person who may derive great benefit from his annual holiday month is the *bon viveur*, the man who habitually eats and drinks too much, who never walks a yard that he can help, and who is on the high-road to gout, Bright's disease, or fatty degenerations. It is for such persons that the plain diet, early hours, regulated exercise, and copious imbibitions of mineral waters of a well-regulated spa work a veritable miracle in a very brief space of time. It is hardly necessary now to insist that in such cases the matutinal, ante-prandial, and evening potations of mineralised water are only one, and probably not the most important, element in the cure. The vital point is that the *tout ensemble* of life and treatment at a good spa constitutes a most efficient remedial agent, and one which the profession as a whole would do well to recognise habitually as part of the ordinary machinery of practice, instead of according it a kind of half contemptuous tolerance. No doubt hydropathy has been,

Digitized by Google

and still is, in some measure allied with quackery, but we can accord it its just place and recognise its real utility, while protesting that its claim to be regarded as a complete system in itself is wholly invalid.

A few general considerations regarding the invalid's holiday may appropriately conclude this article. The place and time having been carefully chosen, attention should be directed to such questions as sight-seeing, exercise, diet, amusement, &c., which are all sure to engage largely the attention of the holiday maker, and on which medical advice may be of essential value. The lethargic individual must be encouraged to make his holiday a time of increased activity; the patient who habitually lives at too high pressure must be warned that his holiday will fail at all points if it fail to afford adequate opportunities for rest; the dyspeptic must be instructed how to guard against indiscretions in food without adopting a practice of modified starvation; the man of one idea, whose heart remains in his study or his consulting chamber, must be tempted to try some unwonted amusement or to essay the cultivation of some new hobby. It would be a serious error to regard such points as trivial and beneath the attention of the physician. On the contrary, they lie at the very root of successful holiday making, and no regard for the proper selection of locality will compensate for their neglect. A holiday misses one of its chief charms and most valuable uses if it does not rest the jaded mind, give fresh play for the sympathies and imagination, and rejuvenate the flagging interest in things outside the narrow groove of everyday life. This it is capable of doing. This it will do if its objects and methods are properly studied and correctly apprehended.

MR. FRANCIS GALTON, whose researches into family history for scientific purposes have already attracted much attention, has published in the *Fortnightly Review* for July an analysis of the returns he has received relating to temper. We differ from the author in his expressed opinion that the data relating to 1981 persons may be regarded as "an adequate number for many deductions;" but he has nevertheless done good service in drawing attention to the subject, and we cannot but look forward with great interest to the time when Mr. GALTON'S further researches will enable people to answer definitely the two questions in regard to which he now speculates on for them. The first inquiry will be, Do good-tempered parents have, on the whole, good-tempered children? and, Do bad-tempered parents have bad-tempered ones? Mr. GALTON'S answers to the first proposition are: "I have forty-three cases where both parents are recorded as good-tempered, and twenty-five where they were both bad-tempered. Out of the children of the former, 30 per cent. were good-tempered and 10 per cent. bad; out of the latter, 4 per cent. were good- and fifty-two per cent. bad-tempered. This," continues the author, "is emphatic testimony to the heredity of temper. I have worked out the other less contrasted combination of parental temper, but the results are hardly worth giving. There is also much variability in the proportion of the neutral cases." We do not for a moment suppose that any physiologist entertains the least possible doubt as to the fact that temper is hereditary. It cannot be otherwise. What is loosely called "temper" depends as directly upon and is in fact a property of the organism—not simply of the cerebrum but of the body as a whole—as tone and timbre are properties of a vocal apparatus or, indeed, of a lifeless musical instrument. Education, training, and collateral influences, of course, qualify the development of individuals as well as families, so that there may, and must, be "much variability" as to the results presented in special cases; but it is, nevertheless, a fact which cannot be questioned, that such general properties as temper are as distinctly hereditary as the organism is itself the outcome of transmitted specialities of material and development. This is admitted by all, even by those who are not prepared to go so far as most of us are compelled to go in the contention that those particular tendencies which culminate in modes of life and action are also hereditary and transmitted, the good or bad tree producing good or bad fruit according to its nature, and the seed which springs from it partaking of its essential character. Mr. GALTON is, doubtless, right in his conjecture as to the rule that good-tempered parents tend to produce good-tempered children, but there is very much more than he seems to take into account in the effect of modifying influences derived from, or exerted by, the respective families of the parents. The resultant of a combination of two forces is not one *plus* the other, but something differing from both and the outcome of the antagonism of contradiction not less than of the influence of affinities acting and reacting upon and from each. The second question in regard to which Mr. GALTON speculates is intended to be the converse of the first—namely, "Do good-tempered families of brothers and sisters have on the whole good-tempered ancestors, and bad-tempered families bad-tempered ones?" In reply to this he says:—"I have 46 good-tempered families, with an aggregate of 333 parents, uncles, and aunts; and 71 bad-tempered families, with 633 parents, uncles, and aunts. In the former group 26 per cent. were good-tempered and 18 bad, in the latter group 18 were good-tempered and 29 were bad, the remainder being neutral. These results," he adds, "are almost the exact counterparts of one another, so I seem to have made good hits in framing the definitions. More briefly, we may say that when the family is good-tempered, as above defined, the number of good-tempered parents, uncles, and aunts exceeds that of the bad-tempered in the proportion of 3 to 2, and that when the family is bad-tempered the proportions are exactly reversed." The general conclusions at which Mr. GALTON arrives are that "great range and variety of temper" are to be found "among persons of both sexes in the upper and middle classes of English society." On the whole, he thinks the women are a little better tempered than the men, but there is not much difference between the sexes in this respect, since about 45 men are recorded as good-tempered for every 55 who are bad, and, conversely, 55 women are good-tempered for 45 who are bad; and that there is a great admixture of good and bad varieties of temper in the same family, albeit temper is undoubtedly hereditary. "Also," Mr. GALTON concludes, "although it exerts an immense influence for good or ill on domestic happiness, it seems that good temper is not especially looked for, nor is ill temper especially shunned, in marriage selection." This last remark, with which the article ends, is another way of stating the familiar proposition that men and women are not drawn together by similarities but

Digitized by Google

rather by the attraction of opposites, as positives and negatives. However undesirable this may appear to be from an ethical or economic point of view, it is beyond question the law of natural selection.

IT is not a little strange that the great Temperance Movement, with its vast literature and the multifarious discussions to which it has given rise, has as yet made no notable contribution to the department of vital statistics. In some measure this is probably due to the circumstance that the effects of an excessive use of alcohol are so obvious and so obviously disastrous that no statistical presentation of them could possibly intensify their argumentative effect. It needs no tabular view of collected facts to prove that habitual drunkenness involves constitutional ruin. But total abstainers are by no means content nowadays to rest their case upon the admitted results of intemperance. It is an opinion devoutly held and widely diffused that the habitual use of alcohol, even in the most moderate quantity, is actually deleterious. The scientific grounds of this view are at present very incomplete, and the ascertained facts of a fragmentary and inconclusive character. It is here that a mortality table representing the experience of that large community which shuns alcohol would be particularly valuable. Not only does the subject furnish a battle-ground to moralists, but it is also of practical and pressing importance in a variety of ways. The almost universal practice of life assurance has given a direct pecuniary value to every circumstance of individual health or habits, which has any bearing upon the duration of human life, and thus the profession of abstinence has come to be an item in the purely commercial relations between the Life Assurance Companies and their assured. While in this and the like ways the question of the effect of alcohol upon human longevity has come to have a universal interest, it has received for some of the continental legislatures a singular and even painful importance at the present time. France, which used to enjoy an enviable reputation for temperance, has, within the past ten years, retrograded sadly in this respect. The number of shops for the sale of alcohol, in proportion to the numbers of the population, is almost half as large again in France as in England; that is to say, where there are seven such shops among ourselves there are ten in France. But it is not only in the quantity of alcohol consumed, but also in the kinds selected, that deterioration has been registered within the past decade, and it is stated on the authority of a Commission recently appointed by the [illegible] to inquire into this subject, that all the familiar consequences of alcoholism are terribly apparent in the [illegible] statistics of to-day. Belgium, again, would seem in [illegible] to be in even a worse plight than France. [illegible] proportion of liquor shops is more than double [illegible], and the consumption of alcohol has reached [illegible] and a half per head of the population, [illegible] children being all enumerated. Thus, [illegible] the influence of alcohol upon vitality [illegible] ways to a position of command- [illegible] importance; and the Life Assurance [illegible] have at command much of the [illegible] Mortality tables are constructed. [illegible] company which cultivates business among total abstainers is accustomed in its [illegible] report to give the expected and the actual mortality in abstaining and general sections respectively into which [illegible] is divided. The last report states:—"Expected claims in the Temperance Section, 271; actual claims, 171. In the General Section 354 claims were expected; the actual claims were 337." These figures would appear to show that the total abstainers do enjoy a very pronounced advantage in point of longevity. But several considerations at once arise to cast doubt on the premisses. What becomes of members who pass out of the Temperance Section? Do they pass into the General Section? If so, it is plain that the favoured section must be relieved of a certain proportion of its burdens at the expense of the General Section, and there is some reason to believe that this is the case with the Society in point. Another circumstance that needs elucidation before any conclusion can be come to as to the significance of these figures is the age distribution through the two departments and the table by which they are tested. Thus it is plain that, in respect both of the consequences involved and the present sources of information, a strong case exists for investigation, and we hope that public spirit, or private interest, or both combined, will before long lead some competent persons to undertake the much-needed operation.

IN an article on "The Holiday Season" which appeared in our last number, we referred to the natural advantages enjoyed by many health resorts situated on our own coast, and included among the number the town of Margate, the climate of which is well known for its bracing qualities. It is this week our duty to speak of Margate in a different sense, and to show how, notwithstanding the benefits which nature has conferred upon her, the local sanitary authority have, by their negligence, rendered the place distinctly undesirable for occupation by those who are seeking to improve their health by change of locality. The condition of Margate will be best understood by the perusal of the report of Dr. DAVID PAGE, Medical Inspector of the Local Government Board, which that Board has just issued. The occasion of Dr. PAGE'S visit to Margate was the increasing mortality from typhoid fever in the borough. Margate has, indeed, for a number of years lost some of its inhabitants from "fever"—the deaths in each year from 1877 to 1885 numbering from one to six, which increased in 1886 to as many as nineteen. This rapid development of fever was necessarily viewed with alarm, and especially as the medical officer of health, Mr. KNIGHT TREVES, ascribed its spread to a probable pollution of the general water supply of the town.

Dr. PAGE says that the water supply of Margate is obtained from a well at Tivoli, on the south-west inland boundary of the town, sunk in the chalk to a depth of fifty-three feet, while an additional supply is derived from a well sunk in the Dane valley. The Tivoli well is that especially open to suspicion, being situated at the edge of a strip of grassy marsh land, which is traversed by a "foul stream, little else than a stagnant ditch," receiving at the lower part of its course drainage from various premises, including a steam laundry, stables, dung-hills, and an unknown number of cesspools behind Marine-

Digitized by Google

terrace. One danger to the well is from a possible back flow of this stream, a circumstance which had indeed been observed, and to check which some attempt had been made by the provision of a penstock; but this is not all, for Dr. PAGE remarks, "a populous neighbourhood entirely dependent upon drainage into cesspools is growing up in the vicinity of this well, and, incredible as the statement may read to those who know the dangers of contaminated water, I have to state that during the present year a row of a dozen houses has been built within seventy feet of the pumping well, the houses having no other means of excrement disposal than into separate cesspools sunk into the chalk for a depth of twenty feet." It is enough to say, in conclusion, on this point, that there is ground for suspicion that one of the adits of the well approaches to within a few feet of these premises.

If the fact that these cesspools were made with the consent of the Sanitary Authority were not sufficiently blameworthy, they have allowed numerous waterclosets to be supplied directly from the mains without the intervention of any cistern or service-box. Margate indeed is apparently expected to thrive under conditions which no active sanitary authority would tolerate, but this will be better understood when the sewerage of the town is considered. Such sewerage as exists is described as fragmentary, for few sewers exist, and the chief of these, owing to defects, becomes choked at times, leading to the flooding of basements and courts. For the majority of houses cesspools are provided—holes in the chalk, containing offensive matter, which the authority leave to be removed at the cost of the householder. Dr. PAGE tells how, rather than incur this expense, tenants will often leave their houses, or throw their slops out through their back doors in order to lessen the pressure on their pits. It is to these conditions that Dr. PAGE attributes the prevalence of typhoid fever.

Enough has been said to show that the condition of Margate is a standing danger to the inhabitants and to every visitor who goes there; the Town Council cannot plead they are without warning. In 1849 more than 120 persons died of cholera. In 1850 the sanitary condition of the town was condemned by the General Board of Health. As long ago as 1873, Dr. GWYNNE HARRIES of the Local Government Board reported that the medical practitioners of the place stated that fever, diarrhœa, and low types of disease were constantly present in the town, and that infants and visitors suffered most from these kinds of sickness. The registers of deaths themselves, he pointed out, afforded no satisfactory index of disease, "visitors sickening of any disease, the onset of which is gradual, return home as soon as they recognise its approach; dying at home of disease with which they were infected in such a town as this, their deaths fail to appear in evidence against it." In 1880 THE LANCET sent a commissioner to Margate, and as a result of his inspection we published an account of its sanitary state, which showed but little improvement had taken place since it was the subject of Dr. GWYNNE HARRIES' report. The town was then, as now, honeycombed with cesspools; such sewerage as existed was faulty to a degree. The water-supply was even then regarded as liable to contamination, and the high death-rate among children indicated the unhealthy conditions under which the inhabitants lived. These evils have still continued; yet Margate is allowed to offend in this manner, apparently trusting to the fact that the official reports of its own health officer are not sufficiently read by the large number of persons who desire to enjoy the fresh breezes which are to be found on this part of the coast.

We trust that the action of the Local Government Board in placing their report on sale, and in thus enabling every inhabitant and intending visitor to peruse it, will teach the town of Margate that there is no economy in neglecting to obey the most elementary teaching of sanitary science, and that the ultimate effect of the report will be to render Margate really worthy of her exceptional natural advantages.

Annotations.

"Ne quid nimis."

THE COLLEGE ELECTION.

THE result of the election of members for the Council of the Royal College of Surgeons is very interesting. Everyone will congratulate Mr. Hutchinson on the large number of votes (none being plumpers) which he received, while the comparatively small number of votes polled in favour of Sir Spencer Wells' re-election may be taken as an endorsement of what we felt it to be our duty to hint at last week—viz., that he should have made way for a younger man. Mr. Willett's success this year will more than compensate him for his unsuccessful candidature last year. His advent to the Council brings with it a man already well up in College matters, and one who has made himself acquainted with what is going on among the Fellows and Members outside the College. Mr. Willett has taken an active share in the proceedings of the Association of Fellows, and, unless we are greatly mistaken, he will strengthen that section of the Council which would unite the College and its constituents at large into a more homogeneous body than they are at present. A noticeable feature of the present election is the small number of voters—less than 200 having taken part in the election. It would thus appear that the exclusive privilege of voting, which the Council at present regard as one of the highest functions of the Fellowship, is not so very highly prized, or surely a greater number would have come forward to exercise it. Doubtless the Association of Members, in presenting their memorial, will point out this fact to the Lord President of the Council. It should be another argument in favour of widening the constituency, with a view to a more adequate representation in the Council of the various elements of the profession.

ADDITIONS TO THE HUNTERIAN MUSEUM.

From the annual report of the Conservator of the Hunterian Museum it appears that the additions to the pathological department during the last year number 121 specimens, besides teratological specimens and calculi. Among them is the complete articulated skeleton of a man affected with osteitis deformans. There is a large and valuable addition to the collection of drawings and photographs, by Mr. Jonathan Hutchinson, Mr. Oliver Pemberton, and the photographs accompanying the Jacksonian Prize Essay. Mr. F. Eve has prepared an appendix to the Pathological Catalogue; this contains descriptions of nearly 400 specimens, and completes the catalogue up to the present date. "The nucleus of a series of specimens for examination purposes has been formed." The revision of the whole series of specimens is completed. In the department of Comparative

Digitized by Google

Anatomy there have been received, amongst others, five skulls from the Hindu-Kush district of India, and new skeletons of birds; whilst the College has purchased a fine specimen of the egg of the Œpyornis maximus (or roc). Several dissections of important parts have been added. These, which are extremely good, keep up the high reputation of the College, and will be most useful to the student. Altogether the additions to the museum are quite as interesting and instructive as in former years, and will fully repay a visit.

SCARLET FEVER AND INSANITARY CONDITIONS.

ACCORDING to a report of a subcommittee of the Sheffield Health Committee, the sanitary condition of the village of Crookes deserves the attention of the corporation. Scarlet fever has been epidemic there, and the Sheffield authority have made inquiry into the possibility that the night-soil which is deposited in the neighbourhood is the cause of the outbreak. They have not come to this conclusion, but have found in the village abundant reason for the rapid spread of any infectious disease from house to house; and they comment in condemnatory terms on the want of proper drainage and the arrangements of middens and on the crowded cottages of the place, and say that the remedy lies in the improvement of sanitary matters in and about the cottages, in getting rid of the middens, in doing away with drains under houses and cesspools in the yard and close to inhabited houses, in providing means for disinfecting infected houses, and in the immediate removal of infected cases to the borough hospital. Until these suggestions are adopted they fear there can be no hope of arresting infectious disease in Crookes when it arises. Scarlet fever has also been prevalent at South Normanton, cases occurring in a house of one room, which was described as a filthy hovel and not fit for habitation; in this one room several persons lived, and the ventilation of the place was most imperfect. The sanitary authority have given instructions for the necessary measures to be taken under the Public Health Act.

THE CONTINUED DROUGHT.

THE absence of rain is causing serious inconvenience in all parts of the kingdom. On June 27th the Liverpool Water Committee had under consideration the report of their engineer, which stated that the total volume of water in store at Rivington had diminished in a fortnight by 232,000,000 gallons, a member of the committee pointing out that in one of the suburban districts, Blundellsands, the want of sufficient water had been very severely felt in consequence of the supply being cut off for some hours each day. In Wales several works are stopped for want of water, and it is feared that, should the drought continue, six thousand operatives will shortly be thrown out of work at Llanelly and the Rhondda Valley. In Swansea water is being searched for in streams and private wells, the town supply having failed. Attempts have been made to supplement the town supply by pumping from disused colliery workings, and, it is said, also from old wells closed years previously because the water was said to be undrinkable, and with the result that the 100,000 inhabitants of the town receive but one-third of the necessary supply. In Ireland the crops are suffering, and in some places it is stated the cattle are dying from heat and scarcity of water. In the north of England rain has fallen, but more is urgently needed. The effects of the drought upon health will probably be [illegible] later. The damage to crops and the failure of [illegible] will undoubtedly have its influence in producing [illegible] the necessity which has been found [illegible] obtaining water from improper sources [illegible] lead to an increased prevalence of enteric fever. But one of the greatest benefits of rain is its power of cleansing the air and earth, and it may be anticipated that an increased diarrhœal death-rate will be found in those towns where this disease is usually prevalent in the summer. On the other hand, the heat of the weather is probably responsible in some part for the absence of small-pox. It is now two months since a single death from this disease was registered in the metropolitan district, and the cases that have occurred have been trifling in number. The effect of heavy rainfall at the conclusion of the drought will be watched with interest, for it may be expected that watercourses will be especially polluted at that time.

THE TREATMENT OF FIBROID TUMOURS BY ELECTRICITY.

FOR many years electricity has been used in the treatment of the diseases of women, and for the last twenty years various attempts have been made to render it valuable in the treatment of fibroid tumours. This has been tried in America, Germany, and France, in the last-named country more especially by Dr. Apostoli, who claims a degree of success not obtained by any other operator. He attributes his success to two facts—the method of operation and the strength of the current. He introduces one pole into the cavity of the uterus when possible; failing this, he forces it into the substance of the tumour, the other pole he places on the abdomen of the patient. The strength of the current employed by Apostoli is much greater than that which has been hitherto employed by others, and he prevents cauterisation of the skin of the abdomen by the use of an electrode of large area made of a material of low conducting power. The uterine pole is used to cauterise and to cause absorption. Absorption is said to be brought about by electro-chemical action upon the tissues of the tumour, contraction and lessening of the blood supply, and coagulation. The means employed are said to be safe, comparatively painless, and successful in the hands of Apostoli. It is as yet too soon to form a definite judgment upon the method, for in other hands it has often failed, has caused serious illness, and even proved fatal. At the same time it cannot be questioned that in certain cases it has proved of great service. It has been followed by diminution of the hæmorrhage and improvement in the general health, diminution in the size of the uterus, and early menopause. Should it prove to possess half the advantages which are claimed for it, it will be a great addition to our present methods of treating fibroid tumours of the uterus.

POOR LAW ADMINISTRATION.

INQUIRY has just been made by an inspector of the Local Government Board into the circumstances attending the suspension by the Brighton Board of Guardians of one of their district medical officers. It is difficult to read the evidence, which is published *in extenso* in the *Sussex Daily News*, without a feeling of astonishment that the time of a Local Government Board inspector, of the Board of Guardians, and of a number of other persons, should be wasted by an examination into complaints as frivolous in character as could be brought against any public officer. The medical officer's manner had, it seems, been displeasing to certain persons, and, as a result, six so-called charges were deemed worthy of investigation. There is no point in the whole inquiry that is of any public interest, the gravest accusation being that of irritability of temper. A large number of the well-known members of the medical profession in Brighton gave evidence in favour of the medical officer, and bore witness to his professional ability, his courtesy to those about him, and his kindness to his patients, and the conclusion of the case is sufficiently

Digitized by Google

obvious. Tho only lesson which can be learnt from the whole case is the necessity for medical men who are not possessed of the most perfectly even tempers to avoid poor-law practice.

THE ADDRESS IN MEDICINE AT THE AMERICAN MEDICAL ASSOCIATION.

DR. JOHN S. LYNCH of Baltimore, in his capacity of President of the Section of Practice of Medicine at the recent meeting at Chicago, glanced at several recent discoveries, "or pretended discoveries," in therapeutics. His address did not profess to be exhaustive, but there was a free expression of personal experience and opinion on current subjects which has its value to a practical audience. He extolled antipyretics: "As I grow older and my experience enlarges, I become more and more convinced that fever is the lethal agent which destroys life in almost every disease in which that functional derangement is present." Hence his praise of antipyretic remedies, amongst which he yielded the palm to antipyrin as very soluble in water, and rarely exciting nausea. Since beginning to use it in November, 1884, he has not seen a single person die of enteric fever, scarlatina, or measles, only one of croupous pneumonia (seen too late); and the duration of life in phthisis, he thinks, is very nearly doubled by it. Of course, this is a very imperfect statement. We should require to know how many cases of such diseases Dr. Lynch has seen. "The dose should be about one gramme, repeated at first every hour until three doses have been taken, and afterwards every three or four hours." On the subject of cardiac stimulants, he reports that he has not experienced the valuable properties attributed to strophanthus, and says it is hardly possible that we shall ever find a better remedy for all cardiac lesions than digitalis, which combines the two valuable properties of energising the heart and stimulating the action of the kidneys at the same time. On the momentous subject of phthisis, which disease is probably more fatal to the human race than war, pestilence, and famine combined, he was rather severe on Koch's bacillus, and still more so on Bergeon's treatment of it. He did not deny that the bacillus existed and was a factor in the case; but he attached far greater importance to hygienic conditions as both more powerful and more controllable. After having given Bergeon's treatment a fair trial, he had nothing to say in its favour. He gave two instructive cases—both men—to show that one may carry a caseous mass in the lungs for years, and yet, with great attention to hygienic surroundings, enjoy good health, or even attain a fair longevity.

DIAPHRAGMATIC HERNIA.

A COACHMAN, aged thirty-seven, was admitted into St. Thomas's Hospital, under the care of Dr. Ord, on July 7th, with symptoms of intestinal obstruction. He was conscious, but intensely collapsed; temperature 98°; pulse 136; abdomen greatly distended, especially in the region of the transverse colon, and perfectly motionless, over-resonant, and rigid. He died in the afternoon in a delirious condition. At the post-mortem examination, there were signs of old pleurisy on the left side; whilst through the left side of the diaphragm projected a portion of the splenic flexure of the colon, with a piece of omentum. The adhesions round the neck of this hernia were firm and old. The large intestine above this hernia was distended, below collapsed. He had first complained of a sudden twisting abdominal pain whilst lying on the grass on July 1st. Vomiting commenced next day, rapidly becoming offensive. He was stated to have been a healthy man, having never been troubled with constipation for more than two days. Had drunk freely.

ALBERT VON KÖLLIKER.

SELDOM have honours been more worthily bestowed than on the great Würzburg anatomist and teacher, who on Wednesday, the 6th inst., reached his seventieth birthday and the fortieth anniversary of his academic work. Preparations had for some time been on foot for the celebration, and the University authorities and the Burschenschaft combined to make it a brilliant success. In the forenoon of the day the *Jubilar* (as the Germans call him) received the congratulations of the rector and the Senatus, and his former and present pupils thereafter tendered him a magnificently bound collection of scientific works, in testimony of their gratitude and goodwill; while illuminated addresses, on the part of the medical faculty and of the Medico-Physical Society (founded by himself forty years ago, and of which he is permanent honorary president), were also presented to him in terms of cordial greeting. The Medico-Physical Society of Erlangen, followed by a distinguished succession of anatomists from Germany and nearly every European country, and, lastly, by civic functionaries of every degree, waited on him to offer their salutations. Telegrams and letters also came in at short intervals all through the day in testimony of the affectionate goodwill of their signatories. Professor von Kölliker was deeply moved and gratified by the whole demonstration, so varied and so significant in its expression. In the evening a great banquet in his honour was held in the Hotel Schwan, and among the company were the Senatus Academicus, the leading members of the medical profession, the Fellows of the Medico-Physical Society, and a numerous representation of students and friends. Toasts and speeches, grave and gay, sped the hours delightfully, and far on in the night the guest of the day was serenaded by the Vocal Union and honoured with a torchlight procession by the students. On the 7th a special entertainment was given by the Burschenschaft to their veteran teacher in the Platz'schen Garten; and on Friday the 8th the Professor invited all his old students, friends, and colleagues to a *Frühschoppen* in the Julius-spital Pavillon. Throughout the three days' proceedings the reciprocity of good feeling was equally honourable to guest and to entertainers, and will long be remembered among the social annals of the University of Würzburg.

THE CLEANSING OF PUBLIC PONDS.

THE continued hot weather, as might be expected, is bringing into prominence various weak points in the machinery of sanitary administration. Among other matters, attention has been recently directed to the impure condition of the ponds in Victoria Park, which, like other pieces of artificial water in the metropolis, are regularly frequented by bathers, and in which, owing it is said to some leakage, the water has not been changed of late so thoroughly as it ought to be. A part of the consequent pollution is no doubt attributable to the custom of bathing, but this is no reason why that custom should be discontinued. Especially in such a season as this, it is most necessary that every due and possible provision should be made for the cleansing of those members of the community to whom a morning bath in their own crowded homes is an impossible luxury. The ponds referred to are for this purpose invaluable to many a poor but cleanly-disposed Londoner, and it would certainly be unfair to deprive any one such of his time-honoured right of immersion, simply because he leaves the water a cleaner man than he entered it. The state of the ponds, however, calls for a remedy. The leak we have mentioned is to be amended as soon as possible; but it has been questioned, with some reason, whether, though it be made good, the gradual renewal of the water in the pond once a day, as now arranged, is sufficient to ensure the

Digitized by Google

purity. Natural lakes, it is true, are self-purifying on the same principle, while much if not all the refuse which enters them and sinks to the bottom is used up as food for water-plants, fish, and other aquatic animals. It may be doubted, however, if the smaller of these ponds could be so easily cleansed if they were commonly used as bathing-places, and certainly some of their kind in London parks are neither so extensive nor so fully stocked with water plants and the like as to enable them to dispense with the occasional services of the scavenger.

THE "UNIVERSITY COLLEGE GAZETTE."

THE issue of this magazine for the 11th inst. is an illustrated one, intended especially for the use of medical students. It contains excellent illustrations of the Yates ward, the hospital, the college, anatomical and pathological museum, library, Flaxman gallery, Wakley Convalescent Home, &c., and, under the head of "Past Worthies," includes an interesting though brief account of the career of James Wakley, M.D., the late Editor of this journal, whose portrait, and that of the late Dr. Wilson Fox, are by no means the least meritorious of the illustrations. Alluding to the Wakley Convalescent Home, with grounds of eight acres, at Longcross, bequeathed, together with a sum of money in aid of its maintenance, by the late head of our editorial staff, to University College Hospital, the *Gazette* states that the Home will be opened shortly for the reception of nine adults and two children, all of the male sex. This limitation as to sex is necessitated by the present arrangement of the house, but it is hoped that before long it may be possible to enlarge the Home, and so get over this difficulty.

CARL VOGT.

FROM Geneva a correspondent writes: "Medicine was conspicuously represented on the evening of Wednesday, the 6th inst., when the grand hall of the University was filled with a gay and distinguished audience to celebrate the jubilee of the Professor of Natural History and Geology. Carl Vogt is now seventy years of age, and forty of these have been spent in the Geneva school, which his scientific and teaching powers have done so much to make famous. The academic orator on the occasion was M. Pronier, a student in medicine, and very happily did he acquit himself of the task of conveying to the veteran *savant* the gratitude of the younger members of the school for the advantages they had reaped from his able and inspiriting prælections. A beautifully designed and executed set of mantelpiece ornaments in bronze was then tendered to Professor Vogt as the special gift of his pupils. Then, in the name of the Senatus Academicus, the rector, M. Pierre Vaucher, congratulated their septuagenarian colleague on a longevity which afforded every prospect of being extended, to the great benefit of the University of which he had for forty years been so great an ornament. This address was also followed by a special gift—an album containing photographs of Professor Vogt's brother professors, including some who had already passed away. Then the Minister of Public Instruction, M. Carteret, concluded the proceedings by a succinct and appreciative account of Carl Vogt's career, and congratulated him, as the author of the 'Zoologische Briefe,' on having won the ear of the non-academic world for discussions of purely scientific interest. Professor Vogt replied, not without emotion, and in admirable taste. He told his audience that till well on in life he had been divided between the rival claims of two favourites, Science and Politics, and though science had gained the day, he never ceased as a citizen, and even as a *savant*, the attentions from time to time paid to her more bustling sister. To the attention of the latter he had worked for [illegible] of the former he was still working for enlightenment. As a teacher it had been his special care not to burden his pupils with facts, but rather to show them the cosmic relations of these, and how they ought to be taken up and handled. Success in science, as in every other intellectual walk, would wait on those who pursued it with all the might at their command. To his masters, Liebig and Valentin, the great chemist and the great physiologist, he owed whatever special training he had brought to his academic work—work which had been materially aided by the civic authorities, and reinforced by his brother professors. Under such support the University of Geneva would improve on her past record, brilliant as that had been. After the guest of the evening had resumed his seat, amid rounds of applause, an adjournment was made to the Brasserie Rohrer at Plainpalais, and there, till a late, or rather an early, hour, under the genial presidency of Professor Gosse, Dean of the Faculty of Medicine, the proceedings took a less formal and much more lively turn—toast and song alternating, with intervals of pleasant general conversation between. Master, pupil, municipal authority, and plain citizen, to the number of about 300, renewed their congratulations to their guest, who once more made his acknowledgments the occasion of happy reminiscence and kindly counsel."

THE INFLUENCE OF SEX IN HEALTH AND DISEASE.

IN the *Australian Medical Journal* for April 15th, 1887, Dr. Jamieson discusses this complicated question within the narrow limits of an introductory lecture. His argument is, briefly stated, that women are more highly organised than men, as proved, not only by moral superiority, but also by intuitive perception, superior grace of form, relative absence of abnormalities, relative absence of idiocy, higher vitality, and comparative immunity from various diseases. We confess that the author has failed to convince us, and that the facts are better explained, in our opinion, by more "brutal" and less transcendental considerations: moral superiority (which is capable of debate), by comparative seclusion from the struggle for existence and its temptations; intuitive perception, by the very absence of the habit of minute reasoning; superior grace of form, partly by sexual selection, but partly by arrest of development; relative absence of abnormalities is not true of *all* abnormalities; relative absence of idiocy, by smaller heads at birth. The question of comparative probability of living at different ages has been many times debated, and seems to depend mainly on greater evolution of the nervous system, and the burden of life in males, and parturition in females. The article is well written, and we do not forget the maxim: "*Audi alteram partem.*"

FRUIT IN SUMMER.

IN spite of the cold winds which prevailed during April and May, the fruit crop thus far has been fairly abundant, and we are not without signs of a moderate rainfall, which ought to ensure for the season at least an average yield. That this is in itself a fortunate circumstance it is needless to assert, and yet it surely implies along with much advantage a considerable risk to the public health. Let it not be thought that we seek to disparage the value of fruit as an article of diet. If ripe and sound, there is every reason why the great majority of people should partake of it freely. Though persons of markedly gouty or rheumatic temperament require to be somewhat sparing in its use, and others with a dysenteric tendency much more so, while diabetics must regard it, in most of its forms, as a forbidden dainty; still its general utility as a stimulant of digestion, a light food, and an aid to the regular action of the bowel, are beyond question. In order to reap the full benefit of its use,

Digitized by Google

however, one or two facts must be kept in view. We must remember that much depends upon its kind and everything upon its quality. Thus the helpful stimulation afforded to the mucous membrane of the stomach by subacid fruits may be turned to good account when the appetite is jaded, as in some atonic cases of dyspepsia. The same slight acidity is valuable in cases of chronic constipation, and acts partly by its chemical attraction for the intestinal juice and partly as a stimulant of intestinal contraction. Other kinds of fruit, again—such as the banana, which abounds in starch—have a distinct nutritive value. The same is true of nuts, in virtue of the albumen, fat, and starch which they contain, but here the question of digestibility comes in, and it cannot be said to have found in the case of man a completely satisfactory solution. As regards quality, the cardinal properties of ripeness and soundness cannot be too strongly insisted on. Fruit which is still unripe is practically a chemical irritant, and in its degree a poison. That which is passing the stage of ripeness is likewise an irritant, and owes its effects to the chemical products of decay or the germ poison of putrefaction. The question of the treatment of such effects need not now occupy us, but enough has been said to remind our readers that some degree of care is needful to enable them to enjoy the produce of the fruit harvest, and that with due care they have nothing to fear.

THE MIDDLESEX HOSPITAL.

WE are pleased to be able to state that the performance of the "Golden Legend," conducted by the composer, Sir A Sullivan, at the Albert Hall on the 13th inst., on behalf of the above institution, was very successful from every point of view. As a musical treat it certainly left nothing to be desired. The singing of Madame Albani was, as usual, superb, and she was most ably supported by Madame Patey, Mr. Edward Lloyd, and Signor Foli. We understand that Sir A. Sullivan had nothing but praise to bestow upon the efforts of the band and orchestra. Dr. Stainer ably presided at the organ. Owing to the garden party at Hatfield, Her Majesty and many of the Royal Family were unable to be present, but his Royal and Imperial Highness the Crown Prince of Germany, who honoured the performance with his presence, evinced the keenest interest throughout, and afterwards expressed his pleasure at having been present on the occasion. We hear that, after all expenses are paid, a considerable sum will be paid over to the hospital exchequer.

THE MUD BATH TREATMENT IN THE CRIMEA.

DR. PHILIPOVICH, who has for many seasons been in the habit of employing the Crimean mud baths in the treatment of patients suffering from various kinds of affections, has just published an article on the subject in the *Russkaya Meditsina*, in which he gives notes of several cases of an interesting nature. His general opinion is that the mud baths may safely be employed in the case of weak anæmic subjects with as much advantage as in those of a robust habit. He does not consider tabes dorsalis a bar to their use, some cases of the kind while in the earlier stages having been very much benefited by this treatment, the nutrition having been improved and the pains decreased. Cardiac patients may be ordered mud baths, but care should be taken that the temperature is not too high, and that the duration of the baths is not too prolonged. In syphilitic cases mercurial inunctions may advantageously be ordered simultaneously with the course of baths; and under these circumstances Dr. Philipovich finds that a far smaller quantity of the mercurial is required than when the inunctions are not combined with mud baths. He has remarked that although the treatment usually shows its effects at the time, there are some cases in which no improvement is apparent for some weeks afterwards, when, perhaps, the patient getting disgusted with the failure of medical men to relieve his sufferings, has betaken himself to quack remedies, which then not unnaturally come in for the credit of having effected what scientific medicine was powerless to do. The classes of cases in which these mud baths are mainly employed are those of rheumatic and rheumatoid pains, neuralgias and syphilis. The results in the case of rheumatic affections seem to have been most encouraging, as out of forty-six such cases thirty-seven are stated to have been completely cured, or, at all events, entirely relieved from pain, while only nine failed to obtain any marked benefit. Of five cases of sciatica three were more or less nearly cured. Of three cases of migraine one was greatly benefited, one slightly so, and the third not at all. Fifteen cases of debility, consequent on serious diseases, came under treatment; of these ten received marked benefit. There were fifteen syphilitic cases; here mercurial treatment was invariably combined with the baths, and very satisfactory results, as a rule, obtained.

SCARLET FEVER IN SCHOOLS.

A FEW cases of scarlatina having occurred among the boys at Christ's Hospital, the warden of that school has written to the boys' parents giving them the opportunity of removing their sons should they think fit, but not recommending the dispersion of the school. The disease is, the letter states, of a mild type, and none of the patients have presented any serious symptom. The action of the school authorities is in every sense of the word a proper one. It states the facts exactly and without any concealment, and leaves each parent to do what he thinks best in his boy's interest. Probably the majority will desire to leave their children where they are, especially if they have other children at home who have not already suffered from scarlet fever. The letter rightly calls attention to the danger of placing boys returning from school under these circumstances with susceptible persons, and mentions the period of time during which each pupil after leaving school should be regarded with suspicion. Christ's Hospital has set an excellent example to other similar institutions.

A BLUNDER AT LIVERPOOL.

WE had hoped that, with the action which is now being taken in Liverpool to provide two non-pauper fever hospitals, the era of mismanagement with respect to infectious diseases was coming to an end; but a resolution which has just been passed by the Hospitals Committee, to the effect that patients are to be charged two guineas, one guinea, or ten shillings a week, coupled as this is with a reminder of the compulsory powers as to repayment under Section 132 of the Public Health Act, constitutes a blunder of the greatest magnitude. If repayment is deemed desirable in certain cases in order to satisfy the consciences of those who enter the hospital, the announcement should have been made just in the opposite way to that in which it has been done. In the first place, the public should have been informed that, since the hospital has been provided and will be maintained for public purposes at the cost of the public, the public will have the right of entry to their own hospital free of cost; and this the more so because everyone who enters will, by removing from amongst the community a source of danger, be conferring a benefit on his or her fellows, and all such persons should be received into the ordinary wards and receive the ordinary fare free of cost to themselves or to their friends. Every other plan always has failed and must still fail. Indeed, there are many hospitals the expense of building which has been a mere waste of public money, because sanitary authorities, having first spent the rates to

Digitized by Google

the extent of some thousands in making hospital provision, have next deterred the sick from entering by wanting to get back a few paltry pounds from those availing themselves of the public provision which has been made. We therefore sincerely hope that Liverpool will rescind this unfortunate resolution, and so remove the greatest hindrance to the proper protection of the public by means of isolation in hospital. There will always remain a certain number of people who will wish to have private rooms and superior accommodation. This should always be paid for; and we understand that, even whilst charging a minimum of three guineas a week, the authorities of the London Fever Hospital cannot meet the demand made upon them for this class of accommodation. But a charge of this sort is a very different thing from a hint at a charge upon the occupants of ordinary wards. True, all authorities say they intend to remit the fee if the patients are poor; but this does not meet the case. It is when the disease is first heard of that there must be an absence of all hindrances if speedy isolation is aimed at, and this can only be effected by making a hospital which belongs to the public free to the public.

CHOLERA IN ITALY.

As we surmised last week, the outbreak of cholera at Rocella, in Calabria, doubtless had its origin by conveyance from the neighbouring island of Sardinia. The cholera rumours of the past week are numerous, and amongst them is a statement to the effect that Catania, on the eastern coast of Sicily, and which was affected in March last, remains the centre of the epidemic. According to one report, there have been two hundred cases in Catania, a hundred and forty proving fatal, and the garrison being severely affected. The disease has also appeared at Caltanisetta and Messina, but only to a trivial extent. At Rocella cases continue to occur. From Paris comes also a report of cases in the island of Sardinia, but Cagliari remains free as yet. The occurrence of cholera in Sicily has led to a large influx of people into Naples, and the authorities there feel that since they are only at the beginning of their sanitary reform, this immigration is by no means unattended with risk.

ELECTRIC LIGHTING ON RAILWAYS.

IN reference to an annotation on this subject which appeared in a recent issue, we are informed that the London, Brighton, and South Coast Railway Company have already ten trains lighted by electricity, and a proposal is now under consideration for lighting the whole of the trains in this manner. The first two trains were tried and tested in every way for two years, and it was the great success of these trains which led to the late extension of the system. The Brighton company has received an offer from the company which holds the patent to light every train and carriage on the line for the same cost as that entailed by the old imperfect oil-lamps, so that the objection of expense is now at an end. The trains, it appears, are popular, and the light is so great a convenience to the passengers that it is to be hoped we shall speedily see the general adoption of so beneficial a system.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:— Don F. Benjumeda, Professor of Clinical Surgery in the Faculty of Medicine of Cadiz, and well known in Spain as a brilliant operator, especially in stone cases. He was seventy-two years of age, and had held his professorship forty-three years. — Dr. Victor Adolf Richter, Ordinator of the Alexander Hospital, St. Petersburg, at the age of sixty-nine.

THE HEALTH OF THE CROWN PRINCE.

HAPPILY there is little to report of the Crown Prince, in whose health the people of this country take so deep an interest, and what little there is is all in the right direction. His Royal Highness's voice, which a week ago was rather hoarse, has now become clear and almost normal in tone, and the condition of the larynx, to all appearance, continues quite satisfactory. The double indication of healthy appearance and returning normal function in the vocal cords is a matter of sincere gratification to all concerned. There is no foundation for the rumour of the Crown Prince's intention to go to Cauterets; such a proposal has never been entertained. We print elsewhere a translation of Professor Virchow's report on the nature of the portion of the laryngeal growth last removed by Dr. Mackenzie.

PROPOSED CHANGE IN FRENCH PROVINCIAL MEDICAL SCHOOLS.

THE provincial medical schools in France are to be shorn of their accessory professorships—that is to say, of their chairs of physics, chemistry, and natural history, the instruction in these subjects being intended to pass entirely into the hands of the professors of the faculties of science. The change is not to be made in a sudden manner, but gradually, the chairs as they fall vacant not being filled up. The proposed change is meeting with a chorus of disapproval from the provincial schools, whose members do not at all relish the idea of such a curtailment of their respective staffs from mere motives of economy. They say that the science required by medical students, as well as by pharmaceutical students, who in many of the schools are taught with them, is different both in kind and in extent from that required by those whose profession is to be purely scientific, and who are preparing for the higher degrees of doctor or licentiate in science, and that if this change is carried out either the medical or the science students, or both, must necessarily suffer. Again, it is pointed out that it is most inopportune, at a time when medicine is every day becoming more scientific, to crush several centres of medico-scientific research, which are constantly yielding good fruit.

THE JAMAICA MEDICAL SERVICE.

THE Government of Jamaica have passed a law compulsorily fixing the scale of fees for medical men in the Government service. We do not know what this scale may be, nor do we know whether any special reason was urged on behalf of this act of legislation, but certainly it requires justification. No doubt it is well that there should be some agreement as to what is proper remuneration for medical service under different circumstances, and the profession in Jamaica might conveniently follow the example of the Manchester Medico-Ethical Association in adopting a scale which would guide them on this point, but such a course is very different from the enforcement by Government of a tariff which is not fixed by the profession. We would strongly recommend all medical men proposing to enter the Government service of Jamaica to consider the position in which they will be placed in regard to their practice.

RURAL ISLE OF WIGHT.

WE are glad to see that the *Morning Post* has added one to the many warnings we have given as to the dangers to health which are so abundant in the rural area of the Isle of Wight. We have on several occasions pointed to the persistent neglect of the rural sanitary authority to act on the advice either of their own health adviser or of the staff of the Local Government Board. For six years little or nothing has been done to mend matters; polluted water, absence

Digitized by Google

of drains, and prevailing nuisances still remain; and the rural sanitary authority were recently selected in a Government blue-book as a type of inefficiency and mal-administration. Our contemporary indicates that the money aspect of the question may come to be the most potent, when visitors learn where conditions inimical to health abound. Some of the towns in the island,—such as Ryde, Ventnor, and Shanklin—have taken some action. Even West Cowes, with its sad need for drainage, its bad bye-laws, and crowding of houses, has done something. But there are so many parts of the island which should be avoided, that we would counsel any who are intending to visit it to get the report of the Medical Officer of the Local Government Board on cholera measures, which was issued last year, and from that volume to find out where they may go with safety.

FOREIGN UNIVERSITY INTELLIGENCE.

Gottingen—Professor Wolfhugel has been appointed an extraordinary member of the Sanitary Board.

Havana.—A laboratory for bacteriological research and for Pasteur's anti-hydrophobia treatment has just been established.

Leipsig.—Professor de Bary, who had been invited to come to Leipsig, has decided to remain at Strassburg.

Marburg.—The name of Professor Gasser of Berne is mentioned in connexion with the vacant chair of the late Professor Lieberkuhn. Professor Nasse has just celebrated his eightieth birthday.

THE Council of the Recreative Evening Schools' Association have resolved to carry on their work in the ensuing winter on an extended scale, and to enable them to do this successfully an appeal for personal help has been sent to all the centres of scientific training in London. The services of at least fifty volunteer teachers are required, and we may express the opinion that to many scientific students the experience in teaching thus gained would be valuable. The work done by the Association is most excellent, and one deserving of every encouragement. Any information will be supplied by the secretary, J. E. Flower, M.A., at the offices of the Association, 37, Norfolk-street, Strand, W.C.

IN reference to the announcement made in our last issue respecting the post of obstetric physician at St. Thomas's Hospital, we may state that the resignation of Dr. Gervis does not take effect until October next. He will then have served the hospital for twenty-eight years—sixteen years as assistant-physician and twelve as full physician. His retirement is due to the pressure of his private engagements, and from a desire not to prolong his connexion with the hospital beyond the time when he can serve it with unimpaired health and energy.

THE following summary of the degrees conferred at the University of Cambridge during the academical year 1886-87 has been published:—Doctors in Divinity, *jure dignitatis*, 2; Doctors of Law, 2; Doctors of Medicine, 8; Doctors in Letters and Science, 7; Doctors of Music, 2; Bachelor in Divinity, 1; Masters of Arts, 351; Masters of Law, 27; Master of Surgery, 1; Bachelors of Medicine, 49; Bachelors of Surgery, 23; Bachelors of Music, 6; Bachelors of Arts, 577; Bachelors of Law, 36. The honorary degrees conferred were LL.D., 6; Litt.D. & Sc.D., 3.

WE regret to learn that a severe outbreak of typhoid fever is prevailing at Warrington. As yet the cause is somewhat uncertain, but it is locally held to be due to defective conditions of drainage.

TWO of the members of No. 6 Company (Wolverhampton) in the 1st Bucks Rifle Volunteer Corps are suffering from typhoid fever, attributed by Dr. Symington to drinking water out of a horse-trough at Slough on the 22nd ult., when the Volunteers went to form a guard of honour to Her Majesty. It is hardly expected that either of the sufferers will recover.

THOSE of our readers who are interested in anthropology will be glad to learn that the General Congress of German Anthropologists meets at Nürnberg from the 8th to the 12th August. The picturesque city, full of varied interest, will be *en fête* for the occasion, and the organising committee have arranged excursions, to which ladies will be specially invited.

AMONG the classes at the third annual International Photographic Exhibition which is to be held in October, we notice that one, Class XII., is open to members of the medical and other learned professions for clinical studies, micro-photographs, photo-micrographs, natural history specimens, &c.

NOTE ON
RECENT FRENCH LIVER LITERATURE.

BY GEORGE HARLEY, M.D., F.R.S.,
EX-PROFESSOR IN UNIVERSITY COLLEGE, LONDON.

WHILE within the last decade English medical literature has teemed with all kinds of books—originals and compilations—on diseases of the liver, the continental press has issued but very few general treatises on that organ, though many special papers on hepatic subjects have appeared in its periodicals. It was therefore with some degree of curiosity that I sat down to read the 880-paged volume which has just emanated from the pen of Dr. Cyr,[1] the curiosity being materially enhanced by my knowledge of the fact that he may justly be regarded as a representative French writer on hepatic affections, seeing that he has already published separate monographs on Cirrhosis, Biliary colic, the Periodicity of Hepatic Symptoms, as well as an admirable little book on Calculous Affections of the Liver. Not unnaturally, therefore, I was led to expect that in this general treatise of his I should find at once and the same time a clear and concise epitome of all the recent French literature on liver disease—a hopeful expectation in which I have assuredly been in noway disappointed. Such being the case, I shall now briefly place before the readers of THE LANCET some of the more important of the gleanings from Dr. Cyr's volume. It is perhaps all the more advisable to do so, seeing that many English practitioners entertain the idea that, as severe liver diseases are much more frequently met with in this country than on the European continent, they have but little to learn from the writings of their continental *confrères* on hepatic affections. This idea is, however, erroneous; for though it is an undoubted fact that from the widespread existence of our great national vice—an over-indulgence in the use of alcoholic stimulants,—as well as our close Imperial connexion with the tropics, the medical practitioners of Greater Britain see, as a rule, far more examples of liver diseases having an inflammatory origin, and consequently also a much greater number of the secondary forms of hepatic affections springing from them—to wit, abscesses, chronic atrophies, cirrhotic ascites, &c.—than other European practitioners, it is, nevertheless, the fact that our continental *confrères* have, probably, even more opportunities of both studying and treating the very large group of liver diseases generally included under the heading "constitutional." Such, for example, as all the varied forms of syphilitic liver affections, as well as the tuberculous, cancerous, amyloid, and other kinds of hepatic tissue degenerations. Consequently, in a systematic treatise on liver diseases like the one now being considered,

[1] Traité Pratique des Maladies du Foie. Par J. CYR, Médecin Inspecteur adjoint des Eaux de Vichy. Baillière et Fils. Paris, 1887.

Digitized by Google

cannot fail to learn many things that are not alone novel, but likewise many things that are useful in a practical point of view.

With these preliminary observations, I now proceed to give a sketch of Dr. Cyr's opinions. The first sixty pages of his book need not detain us, as they are entirely devoted to the anatomy and physiology of the liver, with which I presume all my readers are sufficiently well acquainted to admit me at once to pass on to the practical part of the volume, which commences with an interesting chapter on the symptomatology and diagnosis of hepatic affections in general. In this chapter Dr. Cyr wisely, I think, impresses strongly upon the reader that a jaundiced tint of the skin is by no means necessary to prove the existence of a grave, or even of an incurable, form of liver disease; for, as he says, jaundice may not only be totally absent in the case of hydatids as well as of abscesses, destroying almost the whole of the normal hepatic tissues, but a yellow tint of the skin may be almost equally conspicuous by its entire absence in rapidly fatal forms of malignant liver disease. In fact, his independent observations entirely confirm the opinions I published some years ago, derived from a careful comparison of hospital statistics, which strikingly pointed out the up till then unappreciated fact that ninety-four out of every hundred fatal cases of hepatic cancer are unaccompanied by any distinctly icteric tint, either of the skin or conjunctivæ. Jaundice therefore, contrary to the popular and generally entertained opinion, though a frequent, cannot in any case be regarded as an essential symptom of grave liver disease.

In the chapter on hepatic abscesses I find enumerated the following differential signs in order to facilitate the diagnosis of the exact seat of the suppuration: (Firstly) When the abscess is located in the front convex part of the liver, he says that there is dyspnœa, in addition to marked pain, radiating towards the chest and shoulder, while there is only exceptionally any jaundice present; whereas, when (secondly) the suppuration is limited to the central part of the organ, there is more or less absence of local symptoms, both of the liver itself and neighbouring organs—pleura, lung, stomach, and intestines,—but decided jaundice when the abscess is large. While, again, if the suppuration be limited to the under concave surface, there is (thirdly) an entire absence of all thoracic symptoms, with, at the same time, marked stomachic troubles in the shape of uncontrollable vomiting, more especially when the lobe of Spigelius happens to be the seat of the abscess. The direction of the pain in this case, too, is different; for instead of its radiating up towards the shoulder, it radiates downwards in the direction of the groin.

Dr. Cyr likewise gives an interesting table of statistics of 563 cases of abscess of the liver, collected from various sources, showing the relative frequency of their different modes of termination, the calculated results being as follows:—In 55 per cent. the patient died without the abscess either having burst or been opened; 14·9 per cent. were opened by operation; 10·5 per cent. spontaneously burst into the lung, 7 per cent. into the peritoneum, 5·5 per cent. into the pleura, 1·9 per cent. into the colon, 1·6 per cent. into the stomach and duodenum, and 0·7 per cent. into the bile ducts; while in the whole 563, three opened into the vena cava, two into the pelvis of the kidney, and one into the pericardium.

On the subject of cirrhosis, on which the author has a right to speak with authority, I find that he considers that a chronic atrophying condition of the liver is always ushered in by dyspeptic symptoms—a loss of appetite and distaste for food, accompanied by thirst. Morning sickness is also not uncommon, and the efforts at vomiting are occasionally distressing; the ejected matters being either sour or bitter according to the proportion of gastric juice or bile mixed with the phlegm in them, which is usually very abundant. He further calls attention to the frequency with which hæmorrhages are met with in advanced cases of cirrhosed liver, even fatal hæmorrhages. From his calculations bleedings appear to occur in the proportion of thirty-eight in atrophic and forty in hypertrophic cirrhosis. Although he thinks complete cure is rare in cases of chronically hardened liver, yet he admits that cases of recovery are much more frequently met with nowadays than formerly. And this he attributes mainly to the fact that within the last few years it has become the fashion to entirely abandon the use of alcoholic drinks during their treatment. In the early stage of cirrhosis he strongly advocates the administration of alkaline mineral waters, and that of Vichy in particular. He also recommends, combined with the employment of drugs, the free use of local counter-irritation, even going so far as to counsel the use of the cautery. One of the worst signs which can manifest itself in a case of cirrhosis he regards as that of an augmentation of jaundice, which is not infrequently accompanied by febrile symptoms and an increase of ascites, both of which are unfavourable complications. To the cirrhosis resulting from syphilis he gives special attention evidently regarding it as a most dangerous form of liver affection—and that, too, even when it is unaccompanied with either jaundice or ascites. In this view of the case I think he will be supported by all who have made liver diseases a special study. As might be expected, the two therapeutic agents he most relies upon in the treatment of syphilitic liver disease are mercury and iodide of potassium. I may mention that Dr. Cyr believes that there are a far greater number of varieties of cirrhosis of the liver than we have the least idea of in this country. He says, indeed, that he could easily describe ten or even eleven. I will not, however, attempt to follow him in this endeavour, but merely remark that among other varieties he prominently describes one as that of fatty cirrhosis—cirrhose graisseuse,—which he again subdivides into two varieties, an atrophic fatty cirrhosis and a hypertrophic fatty cirrhosis, which, however, in my humble opinion, might with more propriety be regarded as merely different stages of one and the same form of disease, the hypertrophic being the mere prelude to a subsequent atrophic condition of liver.

The next point which appears to me well worthy of the consideration of all those in the habit of treating liver diseases are his observations on the relative mortality arising from the spontaneous bursting of hepatic hydatid cysts. The following table gives in a clear and condensed form the gist of Dr. Cyr's calculation:—

In cysts bursting into the peritoneum			90	per cent. are fatal.
,,	,,	,, pleura	80	,, ,,
,,	,,	,, bile ducts	70	,, ,,
,,	,,	,, bronchial tubes	57	,, ,,
,,	,,	,, stomach	40	,, ,,
,,	,,	,, intestines	16	,, ,,
,,	,,	,, through abdominal walls	10	,, ,,

While as regards treatment the author, like all others of the advanced school of thinkers, advocates the early puncturing and evacuation of the contents of the cyst, as being at one and the same time the easiest and speediest means of effecting a cure.

Speaking of puncturing hydatids reminds me that I have not referred to Dr. Cyr's special chapter on the surgery of the liver, where, at page 180, he discusses the subjects of hepatic phlebotomy in dangerous cases of acute hepatitis, and puncturing of the distended liver's capsule in the congested indurated stage of the so-called hypertrophic cirrhosis, about which so much discussion took place in our medical journals last year. His remarks under this heading are highly important, and well worth the careful perusal of all who take an interest in hepatic surgery.

This brief sketch of the present state of French liver literature, imperfect though it be, is, I think, sufficient to show that our continental brethren (who I consider are ably represented by Dr. Cyr) are keeping themselves abreast with the rapid advances which are monthly—I might almost say weekly—taking place in the special department of liver pathology and therapeutics.

Harley-street, W.

THE CROWN PRINCE OF GERMANY.

THE following is the full text of Prof. Virchow's report upon the portion of the laryngeal growth removed on June 29th by Dr. Mackenzie. The report is dated July 1st, 1887, and appears in the *Berliner Klinische Wochenschrift* for the 11th inst.

"I received to-day at noon by special messenger from General Physician Dr. Wegner a sealed jar containing the small morbid growth which has been quite recently removed from the larynx of His Imperial and Royal Highness the Crown Prince. The specimen, which was in absolute alcohol, was entire and well preserved, although somewhat shrivelled. It presented a flattened base of a long oval outline five millimetres long and three millimetres broad, whence a hemispherical highly-granulated surface bulged to the height of slightly more than two millimetres. This latter

Digitized by Google

surface had a faint reddish-grey appearance, whereas the base was of a dark-bluish-black, apparently due to the action of an iron preparation, for on being moistened with hydrochloric acid the colour rapidly cleared up and disappeared, leaving behind a faintly yellow surface, which, on the addition of a drop of ferrocyanide of potassium solution, became a deep blue. Even the pale unstained portion of the convex surface gave the same reaction to a less degree. It must therefore be admitted that the iron had affected the whole of the upper surface, but that it was only the parts which were concealed that retained the bluish-black colour, whilst the exposed parts had faded; further that, although the wall had overlain the somewhat flattened base, yet its black colour gave the idea that this part had been similarly exposed to the action of external agents as other parts. Further examination showed that the flattened base was made up in great part of loosely aggregated rounded club-shaped papillary outgrowths, whilst traversing the central part of the base, and following closely its long axis, a small whitish line barely one millimetre in width existed in the line of incision, which was completely concealed by the papillary growths in the vicinity.

"Microscopic examination showed in even a more marked manner than on the former occasion that the surface of the excised portion was wholly beset with papillary outgrowths of very various sizes. It was only in the immediate neighbourhood of the cut surface that a small uninjured zone was found, of quite smooth continuous superficial tissue. In the papillæ, laminated and superficially flattened, large and hard epithelia were seen which composed by far the greatest part of the structure of the new growth; the connective tissue basis was thin, delicate and vascular. No peculiarities of cell formation were noticed. The surface of section consisted of an irregular, soft, and slightly vascularised tissue. Deep tissue layers have not been removed this time as at the first, and still more at the second operation. Neither glands nor nerve trunks were visible. The section seems to have been carried close to the surface, so that only a portion of the mucous membrane was involved in it. Therefore, on this occasion, there was only a little tissue present, and that not easy to treat, whereon an opinion could be based as to the condition of subjacent parts. This tissue did not in any part exhibit an alveolar structure, nor any epithelial deposit or ingrowth. It consisted of delicate connective tissue, which increased towards the surface, but not in the other direction, and in part contained proliferating elements. Nowhere did this proliferation attain the character of independent centres of growth. The excised portion has therefore to a greater extent than that removed at the last operation, the character of a hard compound wart growing on a moderately irritated and thickened surface, and its base does not favour in the slightest the opinion that it is a new growth invading the tissues."

(Signed) R. VIRCHOW.

JUBILEE ADDRESSES OF THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

ADDRESS PRESENTED TO HER MAJESTY THE QUEEN IN PERSON AT WINDSOR BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

To Her Most Excellent Majesty, the Queen of Great Britain and Ireland, Defender of the Faith.

MOST GRACIOUS SOVEREIGN,—We, your Majesty's loyal subjects, the President and Fellows of your Majesty's College of Physicians of London, approach your Majesty with feelings of profound attachment and dutiful allegiance, to offer our sincere and heartfelt congratulations on the occasion of the Jubilee year of your Majesty's reign. We desire to express our deep appreciation of the benefits which we, in common with all the subjects of your Majesty, have derived from the long and auspicious rule of your Majesty in these realms. We thankfully recognise the great advances that the arts and sciences have made under the fostering care of our Gracious Queen, and we desire especially to thank your Majesty for the constant protection that legitimate medicine has, throughout the fifty years that are now past, invariably received at your Majesty's hands. We thank Almighty God that your Majesty has been permitted to exercise for so long a period so beneficent a sway over your dominions, and we earnestly pray that your Majesty may yet live many years to rule this great nation with wisdom and power, and to reign, as your Majesty has ever done, in the hearts of your subjects.

Sealed and signed on behalf of the College,

WILLIAM JENNER, President,

June 27th, 1887. HENRY A. PITMAN, Registrar.

THE HUMBLE ADDRESS OF THE PRESIDENT, VICE-PRESIDENTS, AND COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To Her Most Excellent Majesty, Victoria, Queen of Great Britain and Ireland.

MAY IT PLEASE YOUR MAJESTY,—We, the President, Vice-Presidents, and Council of the Royal College of Surgeons of England, humbly desire to express to your Majesty, in this year of its Jubilee, our grateful sense of the blessings we have enjoyed under your Majesty's long and prosperous reign. No student of our history can fail to recognise the many and great advantages that have been secured to us by science, by the arts, and by legislation during the last fifty years, and we venture to say that in no department of knowledge has there been greater progress than in the science and art of surgery. But we are conscious that, however much of our happiness may be due to the general advancement of civilisation, very much also we owe to the great personal influence for good your Majesty never fails to exercise on all occasions in which the welfare of the country and of your Majesty's people is concerned. We pray that your Majesty may be long spared to reign over us, so that for many years to come the people of your dominion may continue to be blessed by your Majesty's life and example.

In witness whereof, we, your Majesty's loyal and dutiful subjects, have caused the Common Seal of the College to be hereunto affixed this day of , 1887.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Stratford-on-Avon Combined Districts.—For a fourteenth year Mr. G. H. Fosbroke presents a report on the districts included in his combination; these being the Stratford and Evesham urban and the Stratford, Alcester, and Evesham rural districts. On the whole area the death-rate was 14·6 per 1000, it being highest—namely, 17·5—in the Alcester rural district, where some excess of measles, scarlatina, and diphtheria occurred. All available measures were taken by way of school closure, isolation, and disinfection to stay the spread of these diseases; and having regard to the difficulty of taking successful action under Section 126 of the Public Health Act, we are glad to record a case in which a person was convicted and fined for wilfully exposing her child whilst in an infectious state from scarlatina. But as regards disinfection, the means available in the district are very imperfect, and when it is remembered that this was one of the first rural districts that successfully established an infectious hospital, it is not very creditable to find that the neighbourhood is still without any proper apparatus for dealing with infected articles. Evesham has been satisfactorily supplied with water, and the experience of the town deserves recording. After having had a firm footing in the place, typhoid fever has, on the completion of the waterworks, been banished from the town. The voluntary system of notification of infectious diseases works well, were it not for a single medical man who declines to report. Last year Mr. Fosbroke inquired into 247 cases, and the assistance which the notification affords him is stated to be very great. Since 1875 the Alcester sanatorium has received 702 patients, and of these 634 have been cases of scarlatina. As to the age of the patients, 480 were under ten years of age; a statement which must altogether refute the contention that parents will not allow their children to be separated from them when sick. The Evesham urban and rural districts have also combined in the erection of an excellent hospital; and these districts generally have to thank

Digitized by Google

Mr. Fosbroke for the initiative he took some years ago in the matter of effectually protecting the public against infection by means of isolation.

Birmingham Urban District.—In 1874 the death-rate for this borough was 26·8 per 1000, but since then it has been almost steadily declining, and last year it was 19·6. Infant mortality was somewhat considerable during 1886, the large proportion of children who failed to attain to one year of age being the result of an unusual fatality in diarrhœa. And even 27·7 per cent. of the births failed to reach five years of life. These and other matters relating to the vital statistics of the borough are discussed in considerable detail by Dr. Alfred Hill, who is able to show that in one important respect—namely, in the "fever" death-rate, a very remarkable and steady diminution has taken place during the past sixteen years. In 1870 that rate stood at 0·63 per 1000 in Birmingham; now it stands at 0·15. In the general body of the report Dr. Hill discusses the best plan of drainage and watercloset for the labourer's class of dwelling, and useful diagrams are annexed to show the details of the scheme proposed, and which in principle are excellent. Automatic flushing of drains forms part of the scheme, and we shall be glad to learn from future reports that such flushing, when effected with the sewage itself, has answered the expectations set on it. In the borough infectious hospital only two cases of small-pox were received; but, on the other hand, the cases of scarlet fever isolated reached 428. At the disinfecting station 5826 articles were dealt with. Chapters are included in the report giving details as to meteorology, current sanitary work, and such like matters, and included in the latter work we find a record of two thousand cases of disconnexion of sink pipes. Work of this class and on this scale must steadily tend to the reduction of disease and to the general improvement of the health of the community affected.

Ulverstone Urban District.—This town of 10,000 inhabitants had a heavy death-rate of 22·8 per 1000 in 1886, the rate being largely augmented by a severe epidemic of measles, which caused 18 deaths. Then, again, there were 14 deaths from so-called croup of the non-spasmodic type. This latter is not a satisfactory feature in the year's returns. Good water is everywhere available, but some of the inhabitants obtain supplies from dangerous sources, and disease of a low type exists amongst them. Such cases should be dealt with. There is also still some cesspool drainage to which, according to Dr. Thompson, serious defects attach.

Ulverstone Rural District.—In this rural district the death-rate was 15·1 per 1000 during the past year. Scattered cases of typhoid fever were met with in connexion with the use of polluted water, the pollutions being brought about by [illegible] into wells and springs from filthy surroundings, but the [illegible] villages an efficient supply by gravitation has been [illegible]. Incidentally Dr. Thompson refers to an [illegible] made on premises where ensilage was used. [illegible] emanating from the house where the cattle were [illegible] decidedly nauseating, and he thinks that the effect [illegible] as an article of diet ought to receive the serious [illegible] agriculturists and others. At Allithwaite the [illegible] of drainage still stands over.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

[illegible] of the largest English towns 5788 births [illegible] were registered during the week ending [illegible] annual rate of mortality in these towns, [illegible] 17·6 and 18·1 in the preceding two weeks, [illegible] week to 19·6. During the thirteen weeks [illegible] death-rate in these towns averaged 19·8 [illegible] 1·4 below the mean rate in the corresponding [illegible] the ten years 1877-86. The lowest [illegible] last week were 11·4 in Nottingham, [illegible], 14·5 in Halifax, and 14·8 in Wolverhampton, [illegible] the other towns ranged upwards to [illegible] 19·2 in Birkenhead, 26·9 in Newcastle-[illegible] Preston. The deaths referred to the [illegible] in the twenty-eight towns, which [illegible] the preceding two weeks, further [illegible] owing to the increased mortality [illegible] included 267 from diarrhœa, 152 from [illegible] cough, 54 from scarlet fever, 27 [illegible] enteric), 22 from diphtheria, and only two from small-pox. No death from any of these zymotic diseases was registered during the week in Huddersfield, whereas they caused the greatest mortality in Manchester, Blackburn, Leicester, and Preston. The highest death-rates from diarrhœa occurred in Leeds, Preston, and Leicester; from measles in Oldham, Salford, Newcastle-upon-Tyne, and Birkenhead; from whooping-cough in Liverpool, Birmingham, and Birkenhead; from scarlet fever in Blackburn; and from "fever" in Preston. The 22 deaths from diphtheria in the twenty-eight towns included 11 in London, 2 in Portsmouth, 2 in Birmingham, and 2 in Manchester. Small-pox caused 2 deaths in Sheffield, but not one in Greater London or in any of the twenty-six other large provincial towns. The mortality from diarrhœa only slightly exceeded the average for the season. Only one case of small-pox was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease, no new case having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 184 and 199 in the preceding two weeks, were last week 189, and were 17 below the corrected average. The causes of 62, or 1·9 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Blackburn, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Sunderland, Bradford, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20·3 and 19·5 per 1000 in the preceding two weeks, further declined to 18·8 in the week ending July 9th; this rate was 0·8 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 16·9 and 17·0 in Aberdeen and Paisley, to 23·0 in Leith and 26·6 in Perth. The 469 deaths in the eight towns last week showed a further decrease of 18 from the numbers in the previous two weeks, and included 46 which were referred to whooping-cough, 22 to diarrhœa, 8 to scarlet fever, 4 to diphtheria, 2 to "fever" (typhus, enteric, or simple), 2 to measles, and not one to small-pox; in all, 84 deaths resulted from these principal zymotic diseases, against 90, 71, and 85 in the preceding three weeks. These 84 deaths were equal to an annual rate of 3·4 per 1000, which was 0·4 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 28 and 43 in the preceding two weeks, further rose last week to 46, of which 11 occurred in Glasgow, 10 in Dundee, 9 in Edinburgh, and 7 in Greenock. The 22 deaths attributed to diarrhœa, including 6 in Glasgow, 5 in Edinburgh, 3 in Dundee, and 3 in Greenock, showed a further increase upon recent weekly numbers, but were 2 below the number in the corresponding week of last year. The 8 fatal cases of scarlet fever exceeded the number in the previous week by one, and included 3 in Edinburgh, 2 in Dundee, and 2 in Aberdeen. The deaths referred to diphtheria, measles, and "fever" showed a further decline from numbers returned in recent weeks; 2 from diphtheria were returned in Glasgow. Deaths resulting from acute diseases of the respiratory organs in the eight town, which had been 72 and 80 in the preceding two weeks, declined again last week to 76, but were 2 above the number returned in the corresponding week of last year. The causes of 57, or more than 11 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 26·7, 27·6, and 29·4 in the preceding three weeks, declined again to 26·6 in the week ending July 9th. During the thirteen weeks of last quarter the death-rate in the city averaged 28·7 per 1000, the mean rate during the same period being but 18·0 in London and 19·4 in Edinburgh. The 180 deaths in Dublin last week showed a decline of 19 from the numbers returned in the previous week; they included 36 which were referred to measles, 5 to whooping-cough, 3 to diarrhœa, 2 to "fever" (typhus, enteric, or simple), one from diphtheria, and not one either from small-pox or scarlet fever. Thus the deaths resulting from these principal zymotic diseases, which had been 28 and 40 in the preceding two

Digitized by Google

weeks, further rose last week to 47, and exceeded the number in any previous week of this year; they were equal to an annual rate of 6·9 per 1000, the rates from the same diseases being 4·3 in London and 3·6 in Edinburgh. The fatal cases of measles, which had increased in the preceding nine weeks from 6 to 30, further rose last week to 36, exceeding the number in any previous week of this year. The deaths from whooping-cough also showed an increase, while those from the other zymotic diseases scarcely differed from recent weekly numbers. The deaths of infants showed a further decline, and those of elderly persons were also less numerous than in recent weeks. Five inquest cases and 8 deaths from violence were registered; and 51, or more than a quarter, of the deaths occurred in public institutions. The causes of 17, or nearly 10 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon-General John Hendley, C.B., has been granted retired pay (dated June 21st, 1887); Surgeon-Major Isaac Hoysted, F.R.C.S.I., has been granted retired pay, with the honorary rank of Brigade-Surgeon (dated June 20th, 1887).

ADMIRALTY.—The following appointments have been made:—Surgeon Henry Harries, to the *Duke of Wellington;* Surgeon John B. B. Triggs, to the Jamaica Hospital; Surgeon Charles W. Hamilton, to the *Excellent;* and Surgeon William G. K. Baines, to the *Thalia.*

ENGINEER VOLUNTEERS.—2nd Cheshire (Railway): Thomas Castley Bailey, Gent., to be Acting Surgeon (dated July 9th, 1887).

RIFLE VOLUNTEERS.—4th Cheshire: Acting Surgeon John Keay, to be appointed Second Lieutenant (dated July 9th, 1887).—5th Cheshire: Acting Surgeon Walter Needham resigns his appointment (dated July 9th, 1887).—1st Dorsetshire: Acting Surgeon W. H. Williams, M.D., resigns his appointment; also is permitted to retain his rank, and to continue to wear the uniform of the Corps on his retirement (dated July 9th, 1887).—20th Lancashire (2nd Manchester): Arthur Henry Smith, Gent., to be Acting Surgeon (dated July 9th, 1887).

"Audi alteram partem."

MORPHINOMANIA.

To the Editors of THE LANCET.

SIRS,—The interesting paper of Dr. Oscar Jennings in THE LANCET of June 25th, on the relief of the morphia craving by sparteine and nitro-glycerine, opens up a wide field of hitherto uncultivated therapeutics. The mental and bodily suffering of the morphia *habitué*, during his periods of privation, has its analogue in many allied pathological states. That cerebral and systemic ischæmia of the circulation is the explanation of these complex sufferings is rendered probable, not only by the action of remedies known as vascular stimulants in removing the *plateau*, seen in the sphygmograms of such patients, but also by the successful clinical results, generally obtained by giving vaso-dilating remedies with cardiac tonics in cases where there is pronounced cerebral anæmia, and cases where there are indications of exhaustion of the respiratory and the vaso-motor centres.

The outcome of intemperance in morphia, alcohol, chloral, cocaine, and other like stimulants, is the hyper-dilatation of all the peripheral bloodvessels. This starves the brain and other nerve centres, destroys for the time the physiological hyperæmia, which is a necessity of normal neural activity. These drugs, which in small doses stimulate the vaso-motor centres, in large, or repeated small doses, assume an antithetic *rôle* and induce paresis; thus the urgent necessity of constantly repeating the dose. "A hair of the dog that bit him" is the gospel of the weak-brained, tremulous drinker, and the morphia *habitué*, and he finds that life is only possible to him by spurring his weak nerves by morning drams. The *modus operandi* of these remedies, whose therapeusis depends greatly on their undoubted action on the circulation, is rather complicated. Thus, a drug like morphia may become a vaso-constrictor or dilator according to dose, or, like cocaine, it may show this dual action irrespective of dose, or, like ergot, it may act directly on the bloodvessels or on the cord. But whether these vaso-motor remedies act directly or reflexly, through accelerating fibres or inhibitory nerves, the most important point in reference to this and other forms of ischæmia is the behaviour of the veins in the abdomen. These, partaking of the general paresis, suffer undue dilatation, receive more than their share of blood, and as the blood when in the veins is useless for purposes of nutrition or function, it follows that ischæmia of the general circulation is apt to arise under the prolonged or the habitual use of these stimulants.

Dr. Jennings very clearly points out the two factors in the complex suffering of the morphinomaniac, recommending sparteine in the peripheral and nitro-glycerine in the cerebral or mental phases. Of sparteine I have no experience, but can fully endorse all that has been urged in favour of nitro-glycerine as a vascular stimulant. Besides this, it stands boldly out as one of the quickest and best cardiac tonics. This action on the heart, and at the same time its dilating power over the arterioles, render the peripheral circulation vigorous, and is just the remedy, of all others, one would expect to act well in cases of vaso-motor paresis. But it wants help in its action, for in paresis of this kind there is already great dilatation of the peripheral bloodvessels; and, indeed, it is because certain blood areas are increased at the expense of others that the symptoms take the form they do. These symptoms are those of utter exhaustion of the respiratory and vaso-motor centres, similar, but in an aggravated degree, to those feelings and sensations popularly known as nervous exhaustion. It is interesting to note that the more prominent of these symptoms—the yawning, the sweating, the tremulous and engorged hands and feet, the quick pulse and shallow breathing, the mental depression and moral weakness—are common to each and all of these drugs which to many have become a daily curse. As might be imagined, the intemperate, whether in morphia, alcohol, chloral, or other luxuries, are always prone to seek "other fields and pastures new" in their self-indulgence; and the latest and perhaps the worst form of this kind of intemperance is cocainism. In small doses cocaine is a true vascular stimulant, and acts like an ordinary tonic. In large doses its action is decidedly twofold: it stimulates the brain, giving for a short time vigour and strength to the intellectual faculties and almost destroying the sense of muscular fatigue. At the same time it dilates to an enormous extent the peripheral arterioles, as made evident by the full bloodvessels and constant sweating. Here be it observed this latter phase of acute cocainism resembles in its purely somatic state that obtaining in morphia privation or alcoholic starvation. The cerebral exaltation does not last long, and very soon the peripheral misery is pronounced, and this is why cocaine is so dangerous, not only as an aid in the cure of morphinomania or chronic alcoholism, but even as a tonic in nervous debility. My clinical experience in cases of morphia or alcoholic paresis has led me to much the same line of treatment as that of Dr. Jennings. But with the nitro-glycerine I give strychnine, ergot, or minute doses of digitalis. The "nitrite-acting substance"—nitro-glycerine—of itself is not sufficient, and a little tension help is obtained by the addition of digitalis, ergot, or strychnine. It is not merely the partial anæmia of the brain, or the mere blood fulness in the peripheral arterioles, which is to be removed, but it is the sluggishness of the peripheral current and the excess of blood in the venules and larger abdominal veins that give the somatic or peripheral misery felt by all, or most, patients suffering from deprivation of their accustomed stimulant. The excessive sweating, so marked and constant a symptom, is evidently due to the hyper-venosity of the blood and the consequent imperfect tissue change, and in strychnine we have a remedy which, besides stimulating the vaso-motor centre, increases the excitability of the respiratory centre and thus prevents, according to Brunton, the accumulation of carbonic acid. The whole mystery of this induced ischæmia is, therefore, paresis of the vaso-motor and respiratory centres, from habitual over-stimulation resulting in an almost pathological lowering of blood pressure in those vessels carrying the nutrient and oxygenated blood; hence

Digitized by Google

the patient feels for the time as one feels after a serious bleeding. In shock we have, according to Goltz's experiments, paralytic distension of the great veins. Here we have a kind of chemic shock, extreme central and peripheral malaise, the brain deficient as to its physiological congestion, the capillaries handicapped by a pathological venosity. I am, Sirs, yours truly,

JAMES MORE, M.D.

Rothwell, Northamptonshire, July 11th, 1887.

"SURVIVANCE AFTER GUNSHOT WOUNDS OR OTHER INJURIES OF THE HEART."

To the Editors of THE LANCET.

SIRS,—The circumstances under which I ask you to publish a further statement of cases of this kind are simply these: I received a letter through your office on the 2nd or 3rd of May last from Dr. P. O'Connell of Chicago, with whom I had no previous acquaintance, who, after some complimentary allusions to my paper under this heading that had appeared some short time previously in your pages, intimated that if I would send him my address he would send me in return some references or abstracts of similar conditions he had himself collected. The result is given below, and as this gentleman has expressly desired that his communication should appear in THE LANCET, I send it to you accordingly, and ask, nay, respectfully urge, you to accept and publish it on his and my behalf.

I am, Sirs, your obedient servant,

Anriol-road, W., June, 1887. W. CURRAN.

Wounds of Heart not immediately Fatal.

In the *American Journal of the Medical Sciences* for May, 1829, p. 263, is recorded the case of a lad, aged fifteen, "who was shot in the chest and lived for sixty-seven days. On post-mortem, three shots were found lying loose in the cavity of the right ventricle and two in the right auricle." In the same journal for August, 1829, p. 307, Dr. John Redman Coxe refers to several cases in which life was continued for various lengths of time. I think several cases are recorded in Holmes' System of Surgery, second edition, vol. ii.; and in Fisher's Tables, p. 602, are given three cases, one of which lived ten weeks with a bullet in the cavity of the left ventricle, while another lived "some years" with a ball in the cavity of the right auricle.

Velpeau, in his Treatise on Surgical Anatomy, second edition, vol. i., p. 604, gives a case of extensive wound involving the right auricle, the patient living nine years.

Ollivier (d'Angers), in the "Dict. de Méd.," 1834, t. viii., gives a summary of about sixty collected cases, twenty-nine being wounds of the right ventricle. All except two lived not less than two days.

Dr. Babington ("Medical Records and Researches," p. 59) gives a case of bayonet wound (transfixion) of the heart in the region of the tricuspid valve, the patient living twenty-four hours.

Dr. C. F. Dudley (*New York Medical Archives*, March, 1871) reports a case of wound of the right ventricle, the ball being found within, the patient dying on the fifth day. He walked to his room after being shot, was carried by rail to New York next day, a distance of 162 miles, and was with difficulty prevented from going to a dance on the evening of his arrival in New York.

On November 3rd, 1875, M. Tillaux (*Gazette Hebdomadaire de Méd. et de Chirurg.*, of November 12th, 1875) exhibited to the Surgical Society of Paris the heart of a woman who lived eighteen days with a bullet, seven millimetres in diameter, in the cavity of the left ventricle.

In the *American Journal of the Medical Sciences*, July, 1876, p. 295, is given the case of a boy, aged fifteen, with "pistol wound of the heart, the ball passing through both ventricles and right auricle, and lodging at the root of the right lung: death thirty-eight months afterwards." The bullet, found at the necropsy, was conical, ¾ in. long by ¼ in. diameter. This case was originally published by Dr. P. S. Conner in the *Clinic* for May 27th, 1876.

The *New York Medical Record*, December 14th, 1878, has the case of a young man, aged eighteen, with a "pistol-shot through right ventricle, septum, and aorta; ball lying in left ventricle; sudden death on the fifty-fifth day." The bullet, from a Smith and Wesson revolver, was $\frac{32}{100}$ in. calibre.

The *American Journal of the Medical Sciences*, October, 1879, p. 569, contains a case of pistol shot where "the bullet had penetrated the pericardium anteriorly, passed through the muscular tissue of the wall of the left ventricle, 1 in. above its apex, and passed out of the pericardium posteriorly. The furrow in the wall of the ventricle was an inch and a half long, and a quarter of an inch deep, and the edges of the wound were ragged and everted.' The ball, $\frac{38}{100}$ in. calibre, did not cut entirely through the wall of the cavity of the ventricle, as it held water. The man lived thirteen days.

In the "Medical and Surgical History of the War of the Rebellion," part first, Surgical Volume, pp. 530 and 531, are recorded four cases (the fourth case being a doubtful one) where the patients survived a considerable time. The first of these "survived for fourteen days a wound of the right auricle by a round musket ball." "The next case refers to a patient who lived an hour and a quarter after a perforation of the right auricle and left ventricle by a conical pistol ball." "The third is an example of perforation of the left auricle and left ventricle by a pistol ball. The patient lived forty-six hours after the reception of the injury, although the case was complicated by wounds of the abdomen and axilla." I have given you only the headings of these three cases. Each was verified by careful post-mortem examination. In the fourth case, the patient survived two and a half years a supposed musket-ball wound of the right auricle. The attendants and reporters, who made post-mortem examination, declare most positively they found the cicatrix. There is a paucity of details concerning the wound, and it is possible, if not probable, that they (the reporters) mistook the *maculæ albidæ* of Rokitanski for the cicatrix.

One remarkable case of incised wound of the heart is given at p. 534 of the same volume. "After clearly dividing the sternum" (the gladiolus) "the blade" (of a sheath-knife) "had traversed the mediastinum and freely opened the right auricle." The man "expired in about eight minutes."

If you can put your hand on the volume just mentioned, you will find it a storehouse of information on this interesting subject. The reporter of my last reference was tiger-hunting in India. I quote from an article in Frank Leslie's popular monthly, June, 1885, p. 749, column 2. "Afterwards, upon opening this tiger, we found that it had been shot *through the heart*, and had actually run full half a mile after receiving the mortal injury—one of the most remarkable incidents of the tenacity of animal life that ever came under my notice." P. O'CONNELL, M.D.

Chicago, June, 1887.

HAY FEVER.

To the Editors of THE LANCET.

SIRS,—Considerable attention is now being directed to the subject of hay fever. The time of the year when this distressing malady is seen being the hot months it may interest your readers to peruse the following case:—

A. B——, aged forty-three, born of healthy parents; father died at sixty-five years of age, mother living and in "good health of mind and body," aged seventy-six years; has three sisters and one brother, all alive; remembers suffering from hay fever for the past thirty-six years; the symptoms manifesting themselves with great regularity in all parts of the world—West Indies, East Indies, continent of Europe, Egypt, and the Soudan, no climate making any difference, and no matter how great the heat or dust; no symptoms of the disease except in the months of May, June, July, and part of August. The paroxysmal sneezing, the intense itching of the eyes, nose, roof of the mouth and fauces, with the erysipelatous blush on the back of the throat, the deluge of clear watery fluid which runs from the nose and eyes, forming the chief symptoms which attract the attention, have always been preceded by considerable gastric and hepatic disturbance—in fact, a veritable visceral neurosis, which the attack of hay fever when it comes on gives much relief to. At all times of the year the nose has for the past twenty years been a source of trouble, dry crusts forming which have required to be removed either by violent blowing of the nose or by picking away with the finger-nail. Frequently this produced considerable bleeding from the nose, which always gave a feeling of relief. There has been always a considerable infliction of the septum nasi, but no disease was ever known to be present. About January of the present year a round cleanly-punched hole, ulcerating all round its edge, was discovered in the anterior part of the cartilage of the septum nasi, and since then the nose has required the use

Digitized by Google

of the pocket-handkerchief but very little, no hard crusts form, and though the usual symptoms of gastric intestinal irritation have been present to a considerable extent, yet up to the present the local manifestation of hay fever has been absent. There has been an occasional fit of sneezing following the irritation of the nasal mucous membrane by a camel-hair brush, but the so-called functional erectile action of the turbinated tissues is far less than it used to be—in fact, it appears as if the sensitive area which produced the sneezing, itching, and watering of the eyes and nose has been destroyed, and with its destruction the distressing train of symptoms known as hay fever. If this be correct, we can now understand the benefit obtained in relieving the symptoms by deadening the sensitive area by cocaine, nitrate of silver, and such like applications, and may be induced to proceed deeper to the entire destruction of the *materies morbi*.—I am, Sirs, yours faithfully,

July 11th, 1887. J. PERCIVAL HUNT, M.D., F.R.C.S.I.

THE THERAPEUTICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—It is with much pleasure that I have to report that the suggestion made in your columns *in re* the Therapeutical Society has met with warm approval. I have received none but letters of congratulation and the list of members is filling up rapidly. I hope that by the end of next week a strong and representative executive council will have been formed, and then a circular will be issued to members of the profession giving more details, and supported by names of well-known men, which will carry more weight with it than the one already issued with my signature alone. Arrangements have been already made to print and publish a quarterly therapeutical journal, with probably a weekly supplement, for members only. No subscriptions are due from any present joining members until the first general meeting, and of course no expense will be incurred by any beyond the annual subscription. I write this in answer to many inquiries as to when and to whom subscriptions are to be paid. I have to thank you for the courtesy with which you have allowed me to use your columns and valuable space, and trust that the Society will meet with the approbation of yourselves and numerous readers.

I am, Sirs, yours truly,

A. GEORGE BATEMAN,

Longridge-road, S.W., July 11th, 1887. Acting Hon. Sec.

EAST LONDON HOSPITAL.

To the Editors of THE LANCET.

SIRS,—My attention having been called to an article in your last number under the heading "Hospital Management," in which it is stated that my resignation of the chairmanship of the East London Hospital for Children and Dispensary for Women was owing to the irregular attendance at the meetings of the Board of Management, I beg to say that I resigned in consequence of finding myself at issue with the Board on the question of the demolition of an existing building and the erection of a new and very expensive out-patient department. It is true that I felt, and still feel, that had there been a full meeting of the committee at which the resolution to which I have adverted was passed, the result might have been different, and, in my opinion, more practical. I deprecated at the late annual meeting of the governors of the charity any and every thing that might be construed as a reflection upon my friend Mr. Norris, to whom the East London Hospital owes so much, and whose retirement from the treasurership would be all but universally regretted.

I am, Sirs, yours obedient servant,

Mayfield, Chislehurst, July 7th, 1887. THOS. CHARRINGTON.

THE TOWN COUNCIL OF ST. PETERSBURG AND THE MEDICAL SOCIETIES.—The Town Council of St. Petersburg having been requested to grant a piece of ground in Semenoff's-place as a site for a building for the meetings of the various medical societies, as well as for a dispensary for out-patients and for a surgical hospital, has refused to make the grant. The *St. Petersburger Medicinische Wochenschrift* remarks in connexion with this subject that it is not the first time that the municipal authorities have refused a site for a projected hospital which would have been a boon to the inhabitants.

LIVERPOOL.

(*From our own Correspondent.*)

CELLAR DWELLINGS IN LIVERPOOL.

REFERRING to the notice of the Liverpool medical officer of health's annual report in last week's LANCET, it should be stated that the difficulties in abolishing cellar dwellings are very great. These dwellings are clung to with quite as much tenacity as those of "flats" in Scotch towns (which have their sanitary drawbacks), and so long as they are not situated beneath a certain statute level they cannot be pronounced illegal. When times improve and trade revives there will be more encouragement to capitalists to build suitable and sanitary dwellings for the working classes, then the latter will be in a better position to pay increased rents for better accommodation.

INFECTIOUS HOSPITALS ACCOMMODATION.

Referring to the subject of means for isolating fever cases the difficulties are peculiarly great. Liverpool is more densely populated than any other city, and a large number of people are compressed into a comparatively small space than elsewhere. Moreover, the distance from any part of the city to a suburban site is considerable, even taking the nearest point, and, unfortunately, the residents in these localities are not at all inclined to welcome an infectious diseases hospital amongst them. The wonder is that the authorities have been able to make so excellent a beginning as they have.

REMOVALS TO MORTUARIES.

During the last year there were fifty-one bodies removed to the mortuaries provided by the Council under justices' orders on the certificate of the medical officer of health. It is greatly to be regretted that those of the lower classes of this city who are limited to two, or it may be even one room, do not avail themselves of the ample opportunities afforded them of removing their dead to the mortuary, instead of keeping them for days in their midst. This unwillingness to have dead bodies removed prevails extensively amongst Roman Catholics, and as speedy burial is not always practicable, it would be a great advantage if their bishops and clergy would publicly encourage such removal.

SANITARY WORK IN LIVERPOOL DURING 1886.

Some idea of the vast amount of work done by the sanitary authorities here may be judged by the following figures:—The medical officer of health had notices of 453 cases of infectious disease, of which 234 were small-pox, 68 fever, 1747 scarlatina, 1690 measles, and 183 diphtheria. Out of a total of 1147 of the above which were removed to hospital 917 were effected by the sanitary officers. The number of houses disinfected was 2062, and that of privies certified for conversion into waterclosets was 409. As an illustration of the care with which the Adulteration Act has been put in motion, it appears that out of 952 samples submitted for analysis only 9 were found to be unadulterated. Unwholesome meat to the extent of nearly 58 tons and fish exceeding 50 tons in weight were seized and destroyed. The amount of fines and costs was £70; and this is only a small proportion of the work done.

Liverpool, July 12th.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

A ROYAL WEEK FOR NEWCASTLE.

THIS is to be a Royal week in Newcastle. To-day the Prince of Wales with his sons is to arrive in our city; he is to stay four days, visiting the Royal Agricultural Society's show, which is held here after a lapse of twenty-four years. The Prince is also to visit the Royal Mining and Engineering Exhibition, and the far-famed Elswick works, with which Lord Armstrong has been so long and honourably associated. On the last occasion of the Royal Society's show, the attendance was enormous (exceeding 114,000, I believe), and it is to be hoped that the present one will be at least as successful. So far, everything promises well. Up to this there has been a large arrival of visitors. The weather, too, is fine, and warm, with a rising barometer.

Digitized by Google

NORTHERN VOLUNTEERS' COMMISSARIAT.

The Newcastle *Daily Leader* speaks of the great improvement there has been of late years in the way our Volunteers are treated at the annual inspections and reviews, and instances that at a review held at York twenty years ago, the only rations served out to some of the men were nine ounces of pork-pie, a pint of beer, and an ounce of tobacco, although they were away from home for more than twenty-four hours, much of which time was spent travelling in cattle-trucks, dressed only in their thin uniforms, at a season of the year when the air was cold morning and evening.

DROWNING CASES IN THE NORTH.

Every day for the past week there has been a sad record in our daily papers of young lives lost in bathing. On one day no less than six fatal accidents of this nature were recorded. In the great majority of the cases the same heedlessness is to be noticed: the persons lost were unable to swim, ventured into dangerous places, or even did not know how to bathe; for instance, in one of the cases a young man, aged twenty-seven, after bathing ran races with his companions in the fields by the side of the river for more than an hour, and then went into the water again in a highly heated and exhausted state, when he sank to rise no more. The lecture on the Methods of Restoring the Apparently Drowned, given last week by Dr. Hinshelwood, house-surgeon at the North Riding Infirmary, was most opportune. His lecture was given before the Middlesborough Amateur Swimming Club, and he succinctly explained the Marshall Hall, the Silvester, and also the American system known as Howard's. He was assisted in his demonstrations by Dr. Bateman, while Mr. Weddell, the superintendent of the baths at Middlesborough, gave examples of the safest and most expeditious methods of rescuing drowning persons from the waters. The lecturer and his assistants received most enthusiastic votes of thanks from the audience. Such lectures at this season are most valuable.

SUNDERLAND WORKMEN.

The workmen of Sunderland are proverbial for the honourable interest they take in support of their local medical charities. Last week they had their annual demonstration of friendly societies, and had the usual procession to the Avenue Theatre, where a service was held in aid of the infirmary, the Monkwearmouth and Southwick Dispensary, as well as the Sunderland and North Durham Eye Infirmary. The procession, it was noticed, was considerably larger than last year.

DEATH OF DR. ANDREW BOLTON OF NEWCASTLE.

Many old students and practitioners will regret to hear of the death of Dr. Bolton, which took place at his residence in Newcastle on Friday last. Dr. Bolton was best known as house-surgeon to the Newcastle Infirmary, which post he held for many years. He was also one of the secretaries of the Newcastle and Gateshead Pathological Society. About fifteen years ago he resigned his post at the infirmary and commenced private practice, and at once met with very great success. Dr. Bolton, who was in his fifty-seventh year, has left a widow and three children, and was attended in his last illness by Mr. Lightfoot.

Newcastle-on-Tyne, July 11th.

EDINBURGH.

(From our own Correspondent.)

MEDICO-CHIRURGICAL SOCIETY.

At the last meeting of this Society a large number of interesting cases and specimens were exhibited. Professor Grainger Stewart exhibited a patient in whom a bronchiectasis had been cured by excision of ribs and drainage; and Dr. Byrom Bramwell, a case of athetosis and hemiplegia, apparently the results of an injury at the time of birth. Among the pathological specimens was an enormous renal tumour exhibited by Dr. Lundie. Dr. James Ritchie showed a series of specimens of wall papers containing arsenic, giving an account of the clinical features to which they had given rise in each case. To each specimen was attached a reddened tube showing the amount of arsenic obtained from a square inch of each of the papers. This was a very appreciable amount in some of the cases. It was worthy of note that none of the papers exhibited possessed a green colour. They were mostly, but not exclusively, of the cheaper types of wall paper frequently put in bedrooms or nurseries, and there was nothing about their appearance to excite suspicion. Dr. Bramwell showed a series of sphygmographic and cardiographic tracings from a case of aortic regurgitation, in which a presystolic murmur was audible in the mitral area, and in which there is believed to be no mitral stenosis. In describing this case, he gave an interesting account of the theories of the production of the murmur in such cases, specially commenting on that held by the late Professor Austin Flint. Dr. Bramwell also showed a series of slides, photographs, and drawings illustrating cerebral syphilis. A series of casts were shown by Mr. Hare, illustrating the surgical topography of the cranium in regard to determining the position of the fissure of Rolando in the living subject.

THE LINGUAL TONSIL.

Dr. McBride, at the same meeting of the Medico-Chirurgical Society, read a paper on the "Hypertrophy of the Lymphoid Tissue of the Tongue as a cause of Throat Symptoms." He was able to cite a series of typical cases of enlargement of this "lingual tonsil," and gave a clear account of the symptomatology, pathology, and treatment of the condition.

STIFF GREAT TOE IN ADOLESCENTS.

Dr. Cotterill then read a long paper on the above subject, dealing with the various theories of the causation of the condition. His own view is that the lesion consists in a partial relaxation of the tarsal arch, associated with the wearing of too tight and too short boots.

ROYAL HOSPITAL FOR SICK CHILDREN.

It is understood that the directors of this institution are contemplating the advisability of placing a surgeon permanently on their staff and of developing the surgical side of the hospital both as regards treatment and clinical teaching. It is possible therefore that the expected election of an assistant physician may be postponed indefinitely, since, if the addition of a surgeon and assistant surgeon be made to the staff, it will be large enough to undertake the work of the whole institution without further addition.

Edinburgh, July 12th.

ABERDEEN.

(From our own Correspondent.)

THE CITY HOSPITAL.

DR. FASSON'S report on the City Hospital has been in the hands of the Town Council for some time, and while several of the suggestions made for the improvement of the present buildings have been adopted, the most important alterations and additions recommended are still under consideration. At present the hospital consists of four detached pavilions, a "reception block," an administrative block, mortuary, laundry, and engine-house, &c. The pavilions are separated from each other by walls 7 ft. high, and these, Dr. Fasson suggests, should be taken down because they impede the free circulation of air round the buildings. Each pavilion contains a large ward for twelve beds, with ample cubic space and superficial area, and a small ward in which there are three beds, but in which there ought to be only two. The ventilation is said to be imperfect, "inasmuch as that while there are on the roof-ridge two archimedean cowls and two ventilators opening into the chimneys for the extraction of the impure air, there are no inlets for fresh air." There are windows on either side of the ward, but Dr. Fasson says: "Cross-ventilation by open windows is valuable, but not equally safe at all seasons of the year, nor in all weathers, nor, indeed, at all times of the twenty-four hours in a day. It cannot be depended upon for maintaining an equable temperature throughout a ward, and ..... may become a source of danger to the patients." He recommends the making of inlets below each window at the floor level, the air to be allowed to enter either direct or through "an inverted Tobin tube," placed outside the building, and the amount of air entering to be regulated by sliding doors on the lower inlets; in addition, it is suggested that fresh air might be admitted by placing a fillet of wood below the lower sash of a window, raising it about three inches,

Digitized by Google

and thus leaving a space between the two sashes. The heating arrangements are bad, and the pavilions being built of concrete, the walls are thin and absorb damp, so that it is almost impossible to keep the ward sufficiently warm and comfortable. To remedy this Dr. Fasson suggests the building of "a wall of single brick, inside, with an air space of some three or four inches between it and the concrete," while the walls should not be plastered, but covered with Portland cement and finished with a coat of parian; "this with three coats of paint, the last being of varnish-paint, presents a smooth polished surface," which can be washed and easily kept clean. As a means of heating, steam is recommended, because it would not only furnish all the heating power required, but would become an important factor in perfecting ventilation. The bath and latrine accommodation is condemned—the bath because it is fixed and otherwise unsuitable, and a portable one mounted on a frame with indiarubber tired wheels is recommended; and the waterclosets should be replaced by some approved "wash-out' pattern. The flooring of the wards is condemned, because the planks have all become warped, the seams are open, and the floors are very dirty. Dr. Fasson recommends the careful closing of the seams, painting with three coats of varnish, and the frequent application of turpentine and bees'-wax. He thinks the small ward in each pavilion ought to be reserved for the accommodation of "paying patients." He also recommends a special arrangement for the disinfecting of patients as they leave the hospital. His plan is to have a room divided into two compartments, in the one the patient takes off all hospital clothing and then passes into the second compartment, where he has a bath charged with some disinfectant, and dressing in clothes already disinfected he then leaves the hospital without again coming in contact with anything or anyone in the ward. The "reception-block" is condemned, and it is shown how it might be altered so as to accommodate eight beds, which would be available for sporadic cases of typhus and small-pox.

HEALTH OF THE CITY.

The Public Health Committee met on the 6th inst., and in Dr. Thomson's report, which was before them, it was stated that while in May the death-rate was 23 per 1000, in June it fell to 17·43. No cases of small-pox had been reported since June 28th, and it was hoped that the outbreak had been effectually checked. Of the sixteen persons affected, one, a medical student, died. In the City Hospital at the end of June there were fifty-nine cases, twelve of these being small-pox and the remainder chiefly cases of scarlet fever. During the month 145 cases of zymotic disease were reported, and of these nine terminated fatally. The committee were highly pleased with the general improvement in the health of the city.

THE ABERDEEN UNIVERSITY.

The summer session closes on the 15th inst., and the professional examinations begin on Saturday, the 16th. The first competition for the George Thompson Scholarship of £100 a year, tenable for two years, took place last week. There were three candidates, and the successful one has been declared to be Mr. James Johnstone, who has had a brilliant career at the Aberdeen University. The subjects chosen by the three candidates for examination were midwifery, and the diseases of women and children, physiology, and pathological anatomy.

Aberdeen, July 12th.

DUBLIN.

(From our own Correspondent.)

THE CONJOINT SCHEME BETWEEN THE TWO COLLEGES.

THE first professional examination under the new Conjoint Scheme between the College of Physicians and the Royal College of Surgeons took place last week. A very large number of candidates presented themselves, and the rejections were extremely numerous. It is stated that all the ladies who competed were rejected, either at the papers set or the *viva-voce* part of the examinations. It is rumoured that a re-examination will be applied for.

THE DEATH-RATE OF DUBLIN.

At a meeting of the Dublin Town Council last Monday, allusion was made to the comparatively high death-rate of this city. The Registrar-General in his weekly reports, it was pointed out, gave the social position of the various classes who had died during each week. There was, however, one class with reference to which, it was urged, he made no calculation—namely, the social position of the persons who die in the workhouse. The deaths in the Dublin workhouses were about 150 per 1000 persons, which is much higher than in English institutions of a similar kind. The death-rate also among children under one year of age was very high, and Sir Charles Cameron, medical officer of health for Dublin, had recently stated that, with the exception of Manchester, a large manufacturing city, the mortality among children under one year was higher than in any other city in the United Kingdom. A resolution was adopted that the Registrar-General be requested to bring out in his weekly return the proportion, according to their social position, of the persons who die annually in the workhouse. Sir C. Cameron, in a recent report on this subject, has conveyed some wholesome truths. He says: "With our present underfed, poorly clothed, and badly housed working population, we can hardly expect that the death-rate from all causes can be reduced to that of the prosperous cities of England. It is, however, some consolation to reflect that in 1886 we had the lowest mortality since death registration commenced in Dublin; that our zymotic death-rate was well below the average in English towns, and that our general mortality was less than the average general mortality of the chief continental cities. The mortality due to constitutional diseases is, however, still excessive in Dublin; but the measures for lessening it must be sought for in the domain of political economy, as well as in that of hygeia. Just in proportion as the people are well-fed, well-clad, and well-lodged, will they, by reason of their higher vitality, be able to resist the assaults of both constitutional and infective diseases."

Dr. Oakshott's salary (assistant medical officer, Cork District Lunatic Asylum) has been increased by £25 per annum.

Dublin, July 12th.

BELFAST.

(From our own Correspondent.)

THE ROYAL HOSPITAL.

DR. CALWELL, house physician, having resigned, Dr. Dunlop, who was house surgeon, has been elected in his place, and Dr. Powell, Demonstrator of Anatomy in the College of Surgeons, Dublin, has been appointed house surgeon. At the meeting of the Board of Management, at which these elections took place, several of the members present spoke in the highest terms of Dr. Calwell and Dr. Dunlop. I understand that the former was presented on Saturday with a beautiful study table and chair. The following inscription is on the table:—"Presented to Dr. Calwell by the students of the Belfast Royal Hospital, July 4th, 1887." Dr. Calwell is commencing practice in Belfast. Miss Bostock, an English lady from the vicinity of Leeds, has been elected lady superintendent of the Throne Convalescent Hospital. There were a large number of candidates. There will be an election shortly of a matron for the Royal Hospital.

THE BELFAST HOSPITAL FOR SICK CHILDREN.

The intern part of the hospital is at present closed while alterations in, and new arrangements of, the drainage systems are being carried out. It is hoped that everything will be complete next month. The fund for building the Convalescent Home in connexion with the hospital is steadily increasing. It has been kindly arranged that a refreshment tent shall be placed in the Royal Botanic Gardens, and that the profits shall go to this fund. The Board of Management and the medical staff of the Children's Hospital have memorialised the Senate of the Royal University to recognise this hospital as an institution from which the Royal University will receive certificates for attendance on diseases of children, on the grounds that it is the only hospital in Belfast which is entirely devoted to the treatment of diseases of children, that there are forty-five beds and a large extern department, that there is a attending staff of six, and that, although hitherto unrecognised by the University, students of Queen's College, Belfast, have attended in large numbers every year since

Digitized by Google

1875. I understand that the Belfast Ophthalmic Hospital also asks for recognition.

NORTH OF IRELAND BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

The ninth annual meeting of this Branch was held in the Royal Hospital on July 7th, and was very largely attended. Mr. Fagan, F.R.C.S.I., the president, read a paper on "Intestinal Obstruction," and advocated early laparotomy. For the ensuing year Dr. Palmer (surgeon to the County Infirmary, Armagh) was elected president, Dr. Browne (Belfast) and Dr. Dunlop (Holywood) vice-presidents, Dr. Gray (Castlewellen) treasurer, and Dr. Byers secretary. Several interesting contributions were brought before the meeting, and in the evening thirty-two members dined together in the Royal Avenue Hotel, where, under the presidency of Mr. Fagan, and the vice chairmanship of Dr. Palmer, a very agreeable evening was passed.

COUNTY ANTRIM INFIRMARY, LISBURN.

It is announced that Sir Richard Wallace, Bart., has given £200 for improvements to be effected in the co. Antrim infirmary, which is situated in Lisburn. It has been decided to have a new accident and emergency ward, and wire mattresses are to be substituted for the straw ones previously in use in the infirmary. Mr. G. St. George, surgeon to the infirmary, has arranged for a children's ward on the ground floor, and has obtained from friends £30 towards this very useful object.

BELFAST MEDICAL STUDENTS' ASSOCIATION.

At a meeting of this Association, held on Monday, I understand that attention was drawn to the fact that 180 medical students have signed a petition asking that the Union Hospital should be amalgamated with the Royal Hospital for clinical teaching, and a small sub-committee was appointed to look after this matter. Further, it was decided to draw the attention of the Senate of the Royal University to the fact that, although a very large number of Belfast students go up to the examinations, there is only one examiner (Professor Redfern) at the M.B. from Belfast. The students think that if in the future some of the Belfast teachers apply for examinerships in the Royal University, this fact should be recollected.

TERRIBLE TRAGEDY AT RATHFRILAND.

One of the most appalling tragedies that has ever happened in the north of Ireland took place on Saturday in the vicinity of Rathfriland, county Down. It seems that a man, who two years ago was an inmate of a lunatic asylum, armed with a formidable weapon used for trimming hedges set out from Rathfriland about 5 o'clock on Saturday morning, and murdered two women, and so savagely attacked an old man and an aged woman that little hope is entertained of their recovery, as they are at present in an unconscious condition. Several other people whom he met on his journey had narrow escapes. He then rushed into a lake, and coming out of this he entered in a nude condition a house where a woman was dressing her child. Raising his weapon, and exclaiming "Will I? Will I!" he observed two goats in the yard, which he killed. He then betook himself to the lake again, where with great difficulty he was captured. For some time previously it had been observed that the man was in a strange condition, and on Friday it was said he threatened to take his own life.

Mr. Robert Archer Nesbitt, L.R.C.P., L.R.C.S.Ed., has been appointed dispensing medical officer of Donaghadee, in the room of Dr. Stewart, J.P., resigned.

Belfast, July 12th.

PARIS.

(From our own Correspondent.)

THE ANTI-RABIC METHOD.

The report of the English Commission is a great triumph for M. Pasteur, and, with the exception of M. Peter, who still remains refractory to the inoculation, all opposition to the method has momentarily ceased. The last two sittings of the Academy of Medicine have been almost entirely taken up with this question, and notwithstanding two new deaths from rabies after inoculation communicated by M. Peter, M. Pasteur has declined to recognise the competence of the clinical professor either in matters of experiment or of clinique. The occasional failures are overborne by the statistics of the inoculations, and these have not only been proclaimed anew by Professor Brouardel, but have also been endorsed by M. Villemin and Professor Charcot. It is somewhat odd that if M. Peter is incompetent to judge in the matter because he has never made experiments, M. Pasteur should seek the consecration of his method from a body of gentlemen who are nearly all similarly incompetent.

PROFESSOR GERMAIN SÉE ON ANTIPYRIN.

Professor Germain Sée has made a further communication to the Academy of Sciences on the treatment of pain by antipyrin. He now advises that the drug be administered by hypodermic injection in doses of half a gramme in the same quantity of water. The injection is followed by a disagreeable feeling of tension, which lasts a few seconds; and, when this passes off, the pain, whatever may be its cause, at once remits. It has the great advantage over morphine of giving rise neither to vertigo nor vomiting; nor does it produce either the somnolence or the artificial stimulus which lead to morphinomania. Lastly—and this is the great point—to its sedative effect it adds a curative action, which morphia does not possess. The diseases for which Professor Sée would more especially recommend the substitution of antipyrin for morphine are numerous—acute rheumatism, acute gout, herpes zoster, lumbago, ataxia; also in hepatic and nephritic colic, angina pectoris, and acute asthma. "But there is no morbid condition in which it does not advantageously replace morphia; and as we gather experience we shall see antipyrin used in its stead, and so become the preservative against chronic morphia poisoning." The enthusiasm of M. Sée for his favourite remedy is certainly refreshing, but I venture to think that his practical acquaintance with the morphia habit is, to say the least, restricted. Comparatively few of those who have drifted into morphinomania began their injections for the relief of pain, and even should antipyrin possess the virtue claimed for it by Professor Sée, it will not prevent the dangerous coqueting with morphia which has led many able overworked men to adopt it ultimately as an habitual stimulant.

TREATMENT OF PARALYSIS AGITANS BY MASSAGE.

M. Berber has used massage for the relief of paralysis agitans. He states that by increasing the circulatory activity in the muscles it removes their stiffness, facilitates movement, and causes a disappearance of trembling. He advises the *séance* to be commenced by ordinary massage of the muscles and muscular groups, taken up between the thumb and fingers. After a few minutes this should be followed by what he terms flagellation with the ulnar edge of the hand. In a certain number of cases the operation is to be followed by faradisation.

Paris, July 15th.

Obituary.

ALEXANDER H. BARTLET, M.D., F.R.C.S.

DR. ALEXANDER HENRY BARTLET, whose death, at the ripe age of eighty-seven, occurred on the 4th inst., at his residence in Ipswich, obtained his professional education at St. Thomas's and Guy's Hospitals. He obtained the licence of the Society of Apothecaries of London in 1821, the membership of the Royal College of Surgeons of England in 1823, was elected an honorary Fellow in 1844, and took the degree of Doctor of Medicine at King's College, Aberdeen, in 1859. In 1823 Dr. Bartlet commenced practice in his native town (Ipswich), and, having been previously elected surgeon to the local dispensary, was in 1825 appointed surgeon to the county gaol. In the establishment of the East Suffolk Hospital Dr. Bartlet took warm interest, and when in 1836 the honorary surgeons were elected he stood at the head of the poll. To this institution he remained attached over forty years, and when advanced age dictated the necessity for retirement the governors appointed him consulting surgeon to the institution. Dr. Bartlet was well known and highly respected throughout the district in which he resided.

JOHN MEENAN, M.D., M.CH.

WE regret to have to announce the death of another of the younger members of the medical profession in Belfast. Dr. Meenan was the second son of the late Mr. P. Meenan, Spring Farm, Antrim. He commenced and completed his classical studies at H. Malachy's College, Belfast, where he highly distinguished himself, and gained the respect of his professors and the affection of his fellow students. He then studied in Queen's College, Cork, and at the Carmichael School of Medicine, Dublin, where he was a prizeman and medallist in the Practice of Medicine, Chemistry, and Medical Jurisprudence. He graduated in the Royal University in 1885, and in the same year became a Licentiate in Midwifery of the Rotunda Hospital. For some months he was resident surgeon in the Mater Infirmorum Hospital, Belfast, and was subsequently appointed assistant physician. He commenced practice two years ago, and was rapidly gaining a large *clientèle*. Two weeks ago he was seized with an attack of rheumatic fever (from which he had often suffered before), which was complicated with pneumonia. He gradually got weaker, and died on Sunday last.

Dr. Meenan was a man of kindly disposition, and was possessed of great social qualities. He was deservedly popular among his out-patients and professional friends, as well as among the poor whom he looked after at the hospital with which he was connected. The burial took place on Tuesday.

FREDERICK EAST, M.D. (DURHAM), &c.

IN the sudden death of Dr. Frederick East, at the early age of twenty-eight, Clapton has lost one of its best practitioners and one whom it could least afford to spare. Dr. East commenced his medical career at the London Hospital ten years ago, and very soon was looked upon as one of its most distinguished students. After taking the College of Surgeons and College of Physicians' diplomas and the Apothecaries' licence, he graduated at the Durham University, and obtained the gold medal for his M.D. Graduation Thesis in 1883. Almost immediately after commencing practice in Clapton, Dr. East turned his attention to sanitary subjects, and it is chiefly in his connexion with the River Lea Purification Association that his name will be kept green amongst the inhabitants of north-east London. He became secretary to the Association, and it was without doubt mainly through his indefatigable efforts and perseverance that Parliament was induced to legislate finally in the matter.

Dr. East was a member of the Society of Medical Officers of Health, and also held the Cambridge certificate of sanitary science. As boy and man he gave promise of great things, and, though cut off at such an early age, his young life has already borne good fruit, and much of his work must continue to do so in the days that are yet to come. An excellent practitioner, hard working and thoroughly honest in all he did, he possessed all the capabilities for a very successful career. As a true English gentleman, he will be missed by all who knew him.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT a quarterly meeting of the Council, held on Thursday, the 14th of July, Sir T. Spencer Wells, Bart., and Mr. Hutchinson, were readmitted members of the Council; and Mr. Willett took his seat as the newly elected member. The minutes of the last meeting of the Council were read and confirmed.

Mr. Morrant Baker was introduced and admitted as an Examiner in Surgery.

The regulations recommended by the Museum Committee, relating to the duties of the Conservator and Pathological Curator respectively, were read, approved, and adopted, and will be published with the advertisement of the new office.

Mr. James Blake Baily was elected Librarian of the College.

Letters were read from Messrs. Hutchinson and Bryant resigning their positions as Examiners in Surgery. The appointments will be filled up at the meeting in August Mr. Bryant is eligible for re-election.

A letter was read from Mr. W. Morrant Baker resigning his appointment as Examiner in Physiology for the Membership and Fellowship examinations. This resignation will take effect in November next, after the examination for the Fellowship.

A letter was read from Sir Henry Pitman with reference to the extraordinary meeting of the 29th ult., at the Royal College of Physicians.

The President was authorised to nominate members of the Council as a sub-committee, referred to in the College's Land Committee.

A letter of the 8th instant was read, addressed to the President from the Secretaries of University College and King's College, London, forwarding, by direction of the councils of those Colleges, a copy of a petition which has been presented to Her Majesty in Council by the two Colleges, commending the petitioners' prayer to the attention of the President, and expressing their hope that it will meet with the co-operation and support of this College. This was acknowledged, and the secretaries were referred to the resolution arrived at by the two Colleges to proceed independently.

The following appointments were made:—The Joint Professors of Surgery and Pathology: Messrs. Bryant and Barker (subjects of lectures not determined). The Professors of Comparative Anatomy, Physiology, and other subjects: Mr. C. Stewart (subject not determined); Mr. C. B. Lockwood (on Development of the Organs of Circulation and Respiration, including the Pericardium and Diaphragm); Mr. W. H. H. Jessop (on the Pupil and Accommodation); Mr. J. Bland Sutton (on Evolution in Pathology); Mr. W. W. Cheyne (on Surgical Bacteric Diseases); the Arris and Gale Lecturer, Mr. R. Marcus Gunn (on Certain Points in the Anatomy of the Eye). The appointment of Erasmus Wilson Lecturer was postponed until after the appointment of the new Pathological Curator in November. Mr. F. S. Eve was appointed Pathological Curator for a further period of six months under present conditions.

Mr. W. S. Savory was re-elected President of the College for the third time, and Mr. Bryant and Mr. T. Smith were elected Vice-presidents.

The members of the following committees were appointed:—Museum, Library, General Purposes, Jacksonian, Auditors, and Nomination.

The next meeting of the Council will be held on Aug. 4th.

BETWEEN Ramsgate and Dumpton, on the 5th inst., a lad, while bathing, lost his footing, and would have been drowned had not Dr. Gabb, of Guildford, who happened to be on the beach at the time, plunged into the sea and brought him ashore in an unconscious condition.

ON the 7th inst. Her Royal Highness the Duchess of Albany opened three new wards in the National Hospital for the Paralysed and Epileptic, constructed as a memorial to the late Duke of Albany, in Queen-square, Bloomsbury.

CAUSES OF EXEMPTION FROM MILITARY SERVICE.—Notice has recently been given by the Spanish authorities that ringworm and pelada will henceforth be considered as causes for rejecting men as recruits.

Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND. — At recent meetings of the Examiners the following was admitted a Fellow of the College:—

Mc Creery, Benjamin Thomas, Army Medical Staff.

COLLEGE OF PHYSICIANS IN IRELAND.—At the July examinations the following obtained licences in Medicine and Midwifery of the College:—

MEDICINE.—Edward Lloyd Aherin, George James Burke, Eugene Byrne, William Edward Corbett, Norbert Sydney Durrant, Daniel Henegan, Francis Blake Knox, John Irwin Moore, Robert Garven Nesbitt, J. Joseph O'Connell, Reginald Rygate, Reuben Turner, Ninian Wildridge Woods.

MIDWIFERY.—Eugene Byrne, Thomas Carr, Edwin Tyrrell Cummings, Alfred Russell Darley, Norbert Sydney Durrant, John Irwin Moore, Robert Garven Nesbitt, Reuben Turner, Ninian Wildridge Woods.

At a special Examination held on June 27th and following days the undermentioned obtained licences in Medicine and Midwifery:—

MEDICINE.—Benjamin Badcock, John Joseph Byrnes, Thomas Carr, Oswald Herbert Edwards, John Augustine English.

MIDWIFERY.—Stafford Mouritz Cox, John Augustine English, Richard Blayney Wrightson.

The following has been admitted a Member:—

Bewley, Henry Theodore (Exam.).

THEIR Royal Highnesses the Duke and Duchess of Connaught opened, on the 13th inst., a new children's ward in connexion with the Westminster Hospital.

DR. VAUGHAN, on the 13th inst., in the absence of Lord Cross, distributed the medals and prizes gained by the students at Guy's Hospital Medical School.

THE ceremony of formally opening the new Hull and Sculcoates Dispensary was performed by the Mayor, on the 6th inst.

THE Paisley Police Commissioners have approved of plans for an addition, at a cost of £4000, to Paisley Infectious Diseases Hospital.

THE "Founder's Day" of the Hospital for Incurables, Putney, was celebrated, on the 5th inst., by a réunion of the friends of that institution.

NAVAL MEDICAL SUPPLEMENTAL FUND.—At the quarterly meeting of the directors of the fund, held on the 12th inst., Sir W. R. E. Smart, K.C.B., M.D., Inspector-General, in the chair, the sum of £80 was distributed among the several applicants.

THE annual inspection of the Leavesden Asylum by the managers of the Metropolitan Asylum District took place on the 9th inst. The visitors expressed their satisfaction with the condition and management of the institution.

ON the 4th inst. the Marquis of Lorne formally opened the National Smoke Abatement and Health and Home Exhibitions, which have been arranged within the Albert Palace at Battersea.

ROYAL MEDICAL COLLEGE, EPSOM. — "Founder's Day" was celebrated at Epsom College on Wednesday, July 6th, and in consequence of the exceedingly favourable weather the visitors were very numerous. On the platform, the head master, the Rev. W. Cecil Wood, M.A., was supported by Sir Joseph Fayrer, M.D., K.C.S.I., Sir Edward H. Sieveking, M.D., Mr. J. Lumsden Propert (son of the founder), Dr. George C. Jonson, Rev. E. W. Northey, M.A., Rev. R. Ewing, and Dr. John H. Galton. The distribution of prizes took place in the large schoolroom, which had been most prettily decorated by the boys for the occasion, the ceremony being interspersed with the customary speeches, scenes, &c. The proceedings closed with the singing of the "Carmen Epsomianum," after which cheers were called for the Council, the ladies, the masters, and Mr. Powles, one of the masters about to leave. The popularity of this gentleman was evinced by the vociferous and hearty way in which the boys responded to the last-mentioned call. A move was next made to the grounds, where, under the trees, refreshments had been tastefully laid out. A selection of music played by the Epsom band was highly appreciated, and greatly helped to enliven the proceedings in the open air.

MEDICAL NOTES IN PARLIAMENT.

Prisoners under the Vaccination Acts.

IN the House of Commons on the 11th inst., in reply to Mr. Channing, Mr. Matthews stated that it is in accordance with the existing law and prison rules that prisoners under the Vaccination Act should be ordered to pick oakum, but prisoners sentenced to simple imprisonment without hard labour cannot be placed on the treadwheel, and can only be employed on labour of the lightest description. There are no special rules for prisoners under the Vaccination Acts. It is the sentence which governs the treatment, and the same sentence involves the same treatment whatever may be the Act authorising it.

Foreign Paupers in England.

On the 12th inst., in reply to Mr. Agg-Gardner, Mr. W. H. Smith stated that the question of restricting the importation of foreign paupers was under the consideration of the Government. It was a question of much difficulty, and he was unable to fix a time when it would be possible to legislate upon it.

Ventilation in the House.

Mr. Bond, on behalf of Colonel Hambro, asked the First Commissioner of Works whether he was aware that there was a cellar in the House of Commons, the superficial area of which was 18 ft. by 12 ft., into which no natural light or fresh air could enter, or foul or heated air from the gas, which was always burning, could escape from, except through the doorway, which opened into a passage lit with gas and was nineteen yards from the external atmosphere, and that in this cellar, the temperature of which was seldom below 80°, three men in the employment of the House had to work at a dirty and laborious occupation on an average of fifteen hours a day throughout the session; and whether he would take immediate steps to have this cellar closed as a work-room.—Mr. Plunket, in reply, stated that the cellar to which his attention had been called was really a scullery used in connexion with the kitchen and the members' dining-room, and was in a convenient position for that purpose. He had inquired into its sanitary condition, and while he found that the drainage had been quite recently renewed and was in an excellent condition, the ventilation was undoubtedly in a bad state. There was, however, an air shaft from the ceiling which had not been used for some time. This shaft has now been put in use, with the result that a considerable current of air was now passing through the room.

Police Uniforms.

In reply to Mr. Quilter, who asked whether the Government would consider the desirability of supplying to the police a helmet of a lighter colour, and something in the nature of a blouse for wear on duty during the summer months, Mr. Matthews stated that the Chief Commissioner was in favour of the present system of clothing, thinking that in a variable climate like ours there was more danger from wet and cold than from heat. He was not, therefore, prepared to advise any change.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BENSON, ALFRED, M.A., M.B.Oxon., M.R.C.S., has been appointed Medical Officer to the Paddington Provident Dispensary, vice W. V. Lindsay, M.D., deceased.

BOXALL, FRANK, M.R.C.S., L.R.C.P., L.S.A., has been appointed Resident Medical Officer to the St. Pancras and Northern Dispensary.

CARTER, GRAHAM A., M.D. Mar. Col. Aber., L.R.C.S. Ed., has been appointed Medical Officer for the St. Chad District of the Lichfield Union.

COX, B. OWEN, L.R.C.P.Ed., L.R.C.S.Ed., L.F.P.S.Glas., has been appointed Junior House-Surgeon to the Westminster Hospital.

HARRIS, ALFRED, M.B., C.M.Ed., has been appointed Medical Officer for the Croxton District of the Thetford Union.

MORTON, JOHN, M.B.Lond., M.R.C.S., has been appointed Medical Officer to the Guildford Post Office.

MOXON, WILLIAM, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer of Health for Matlock.

OWEN, R. CHAMBERS, M.R.C.S., L.K.Q.C.P., L.M., has been elected Assistant Surgeon to the Liverpool South Dispensary, vice Mitchell, resigned.

PERKINS, W. H., Ph.D., has been appointed Professor of Chemistry in the Heriot-Watt College, Edinburgh.

WALSH, ROBERT W., M.R.C.S., L.S.A., has been appointed House-Surgeon to the Clinical Hospital for Women and Children, Manchester.

WOOD, FREDERIC C., L.S.A., has been appointed Ambulance Surgeon to the Liverpool Royal Southern Hospital.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BIRMINGHAM GENERAL HOSPITAL.—Resident Medical Officer. Salary £130 per annum, with residence, board, and washing.—Two Assistant House-Surgeons. No salary, but residence, board, and washing will be provided.

BRISTOL ROYAL INFIRMARY.—Obstetric Physician.

CUMBERLAND INFIRMARY, Carlisle.—House-Surgeon. Salary £70 per annum, with board and lodging.

FEMALE LOCK HOSPITAL, Harrow-road, W. — House-Surgeon. Salary £100 per annum, and board and lodging.

Digitized by Google

GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury, Manchester.—Senior and Junior Resident Officers. Salary £100 and £80 per annum respectively, with apartments and board.

HARTLEPOOLS HOSPITAL.—House-Surgeon and Secretary. Salary £60 per annum, with board (exclusive of beer, wine, and spirits), lodging, and attendance.

LEEDS BOROUGH HOSPITALS.—Resident Medical Superintendent. Salary £150 per annum, with board and residence.

LONDON FEVER HOSPITAL, Liverpool-road, N. — Assistant Resident Medical Officer. Salary £120 a year, with board.

NORWICH FRIENDLY SOCIETIES' MEDICAL INSTITUTE.—Resident Medical Officer. Salary £220 per annum, increasing £10 per annum for three years.

RIPON DISPENSARY.—Resident House-Surgeon and Dispenser. Salary £100, with furnished apartments, coals, and candles.

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, Ventnor. — Assistant Resident Medical Officer. Small honorarium.

WESTMINSTER GENERAL DISPENSARY, Gerrard-street, Soho, W.—Honorary Surgeon.

YORKSHIRE COLLEGE, Leeds. — Professor of Anatomy. — Demonstrator of Anatomy. Stipend £150.

Births, Marriages, and Deaths.

BIRTHS.

ADAM.—On the 6th inst., at Malling-place, West Malling, Kent, the wife of James Adam, M.D., of a son.

ALLEN.—On the 12th inst., at Oak Lodge, Stanmore, Middlesex, the wife of W. Hamilton Allen, M.B., of a son.

BARR.—On the 8th inst., at 1, St. Domingo-grove, Liverpool, the wife of James Barr, M.D., of a daughter.

BURTON.—On the 5th inst., at Lichfield-street, Burton-on-Trent, the wife of Leonard Burton, L.R.C.P.Lond., M.R.C.S., of a son.

COUNSELL.—On the 8th inst., the wife of Herbert Edward Counsell, M.R.C.S., L.R.C.P., of a daughter.

DUKE.—On the 5th inst., at Pevensey-road, St. Leonards, the wife of Edgar Duke, M.R.C.S., of a daughter.

LANCASTER.—On the 28th ult., at Neston Lodge, Lewisham High-road, St. John's, S.E., the wife of H. F. Lancaster, M.D., of a daughter.

MACKIE.—On the 12th ult., at Alexandria, Egypt, the wife of James Mackie, M.B. Aber., L.R.C.S.Ed., C.M.G., of a daughter.

ROSS.—On the 7th inst., at 9, Pavilion-parade, Brighton, the wife of Douglas M. Ross, M.B., M.R.C.S., of a son.

THIELE.—On the 13th ult., at Peshawar, India, the wife of Surgeon H. Thiele, M.S., of a son.

WILSON.—On the 2nd inst., at Sparrows Herne, Bushey, Herts, the wife of Daniel Wilson, M.D., of a son.

MARRIAGES.

ARCHER—BEVILLE.—On the 6th inst., at St. John's, Notting-hill, Herbert Ray Archer, M.D.Lond., to Rosita Evelyn Elizabeth, only daughter of the late Charles Wallace Beville, Esq., of the 12th Bombay Native Infantry.

LAUNIA — LUSHER. — On the 7th inst., William Benjamin Launia, M.R.C.S., to Mary Louisa, younger daughter of Edward Lusher, Esq., of Montreal, Canada.

LUNN—MOORE.—On the 12th inst., at the Parish Church, Middleton, the Rev. H. S. Lunn, M.D., to Ethel, eldest daughter of the Rev. Canon Moore, LL.D.

MACGREGOR—REDDIN.—On the 6th inst., at St. Mary's, Poole, Dorset, Donald MacGregor, L.R.C.S., L.R.C.P.Ed., to Harriette, younger daughter of the late Edmund Reddin, Esq., of Albury House, Clapham, Surrey.

MOUAT-BIGGS—TICKELL.—On the 5th inst., at Christ Church, Cheltenham, by the Rev. Morley B. Saunders, M.A., of Bristol (uncle of the bride), assisted by the Rev. E. A. Tickell, M.A., of Ulrome, Yorkshire, and the Rev. C. V. Childe, Vicar of Christ Church, Charles E. F. Mouat-Biggs, M.R.C.S., L.R.C.P., of Malmesbury, Wilts, to Mary Louisa, only daughter of Commander Tickell, R.N., of The Lypiatts, Cheltenham.

ROCHE — JOHNSON. — On the 5th inst., at Holy Trinity Church, Folkestone, Surgeon-Major A. W. Roche, Army Medical Staff, to Louisa Mary Johnson, only daughter of the late Sir Henry F. F. Johnson, Bart.

WEARING—COMER.—On the 7th inst., at St. Margaret's, Anfield, Richard Wearing, M.D.Ed., to Helena Blanche, younger daughter of George Comer, of Larkfield, Wavertree.

DEATHS.

IRWIN.—On the 11th ult., at Buttermere, Cumberland, Henry R. Irwin, of Darlington, Surgeon, aged 47.

SMART.—On the 10th inst., at 65, Craven-street, Birkenhead, Bath Charles Smart, M.D., F.E.S., late of Strangeways, Manchester, aged 49. (Interred at Bidston Cemetery.)

STEVENS.—On the 11th ult., at the Episcopal residence, Philadelphia, U.S.A., the Right Reverend William Bacon Stevens, M.D., D.D., LL.D., Bishop of Pennsylvania, in the 72nd year of his age.

WRIGHT.—On April 27th, at 2, Carlton-terrace, Wynyard-square, Sydney, N. S. Wales, from apoplexy, Ellen, beloved wife of Horatio G. A. Wright, M.R.C.S.Eng., L.S.A.Lond., aged 59.

WRIGHT. — On May 10th, at 2, Carlton-terrace, Wynyard-square, Sydney, N. S. Wales, after many years of patient suffering, Annie, beloved daughter of Horatio G. A. Wright, M.R.C.S. Eng., L.S.A.Lond., aged 35.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

DOES THE ACT OF 1886 GIVE COMPLETE QUALIFICATION TO ALL REGISTERED PERSONS?

Enquirens.—Clause 6, like many other parts of the Medical Act of 1886, is somewhat ambiguous. But in connexion with the repeal of the corresponding clause (31) in the Act of 1858, it does seem capable of the construction put on it by our correspondent. At the same time saving Clause 24 must be taken into account, and would seem to leave the privilege of practitioners registered before the appointed day *in statu quo*.

Dr. Tizard.—The fact may be mentioned more conveniently in a notice of the annual report on the health of the district.

Dr. John Caddy.—The discourse appears to have but a very faint bearing on medicine.

Mr. Mould is referred to a general notice at the head of this column.

THE PORTRAIT OF SIR WILLIAM JENNER.

To the Editors of THE LANCET.

SIRS,—I am convinced that, as usual, you spoke the voice of the profession in your remarks on the proposed presentation to Sir Wm. Jenner of his portrait by Mr. Holl and its replica to two colleges. That the profession will respond to the opportunity thus given, manifesting their admiration and esteem for the distinguished President of the College of Physicians, there cannot be a doubt. I have, however, a suggestion to offer which I venture to think will meet with the approval of physicians and surgeons generally, but more especially of those who practise in the provinces, and may therefore not have an opportunity of seeing either the original or the portrait as often as they could desire. It is that to each subscriber a photograph of the picture should be presented. May I take the liberty of making this suggestion through the columns of your highly valued journal? I am, Sirs, yours very faithfully,

Park-street, W., July 5th, 1887. A. B. KELLY.

SPORTS AND SPOILERS.

To the Editors of THE LANCET.

SIRS,—Can nothing be done when the United Hospital Sports come round next year to keep the ground free from bookmakers and worse? The "two to one bar one" fraternity were in full attendance at Stamford-bridge this year, and carried on their trade in the most open manner, though without any actual shouting, or any of their usual paraphernalia. Surely this is as avoidable as it is out of place at a meeting of the kind. I offer no suggestion, but I think it should be publicly known.

I am, Sirs, yours faithfully.

July, 1887. LATIN GAMES.

PHOTOGRAPHS OF THE LATE DR. MOXON.

Philo Pilo.—Unfortunately there is no very good photograph of this physician, whom we all miss so much. Two photographs were taken by Mr. Barraud of Oxford-street, and he still has the negatives. The one representing Dr. Moxon standing was taken for the Medical Congress group.

Mr. W. Blake Marsh.—By the new French regulations great difficulties are thrown in the way of English and other foreign medical men wishing to practise in France, it being now compulsory for such to take the M.D. of the University of France at Paris, or at one of the provincial Faculties of Medicine. In Italy authority to practise can be more easily obtained; generally, we believe, without any examination in the case of medical men with English qualifications. Our correspondent should apply to Her Britannic Majesty's Consul at Rome.

Mr. E. T. Yeates.—The card is in very bad taste, and would justify remonstrance, if not refusal of professional amenities.

THE PROPOSED REGISTRATION OF FOREIGN DEGREES.

To the Editors of THE LANCET.

SIRS,—I notice in your issue for July 9th a letter on the above subject. The arguments of the writer are plausible, but a little consideration reveals in them several flaws. Take the following statement, for instance:—"It seems reasonable to suppose that no Englishman would go abroad for his degree if he could get one as easily at home." I grant this; but there are many reasons why an Englishman may find a foreign degree more easy to obtain other than the intrinsic easiness of the examination, which "Briton" appears tacitly to assume to be the only reason. Suppose, for instance, his parents reside at a foreign university town, it would obviously be more convenient to take his degree at that university. Suppose that expense is an object, and that he can only afford that degree which will cost him least, why should the Medical Council refuse to acknowledge the only degree which he can afford to obtain? One can scarcely reside at Oxford or Cambridge at an expenditure of less than £200 a year, whereas one can easily live in London with an income of £100. The expenses, therefore, of a candidate for a degree at Oxford or Cambridge will be £200 a year for three years, plus £100 a year for two years' study at London; in all, £800. The expenses of a candidate for a foreign degree are £400 for the four years' study in London. Here I do not take account of the fees; but, even supposing that they are not much greater in England than abroad, the total expenses of an English degree are nearly twice as much as those of a foreign one. But the expense may not be the sole objection to residence at an English university; it may be inconvenient from other causes, and it is unquestionably the inconvenience of the residence which drives so many medical men to take their degrees abroad, and not that the examinations themselves are intrinsically easier. And even if an Englishman with a foreign degree were wrong in assuming that it "implied some *professional* superiority over his untitled brother practitioners," the public would be right in thinking that it implied a superiority of another kind, a superiority in pluck and determination, which has impelled him not to allow himself to be beaten by the difficulties placed in his path, but to persevere in the endeavour to obtain from a foreign country those rights which have been denied to him in his own. To say that the registration of foreign degrees would "injure" anyone is no argument whatever against their registration; or, if it be so, the injury done to their holders by the present system is equally an argument in favour of their registration. "Briton's" last argument cuts both ways. If it be "unjust to register any foreign degree, unless it implies a higher professional knowledge than any British qualification which does not confer a similar degree," surely it must be equally unjust to refuse to register a foreign degree which implies a higher professional knowledge than a British qualification which does confer a similar degree.—I am, Sirs, yours faithfully,

July, 1887. E. OSBORNE FOUNTAIN, B.A.Cant., M.D.Brux.

Mr. Edward D. Buss.—Our correspondent is a little hard on the letter specified. These minor points of practice may profitably be the subject of report from time to time.

An.—We are not aware that the point has been definitely decided, though the current belief is in favour of the affirmative view.

THE CLIMATE OF ILFRACOMBE.

To the Editors of THE LANCET.

SIRS,—Allow me to take exception to a remark in your article on the Holiday Season in your last issue. Speaking of the various seaside places you say: "Scarborough and Cromer are two of the most bracing English marine resorts, while Ilfracombe represents the opposite pole." It is an error to suppose that the climate of Ilfracombe is relaxing, as anyone who has experienced the delicious and invigorating breezes during the last six weeks, when the country has been scorching under the rays of an almost tropical sun, can easily testify. If the freedom from frost and snow in winter and the bracing breezes of our summers were more known, the beauties of this charming place would be even more appreciated than they already are.

I am, Sirs, yours obediently,

Ilfracombe, July 11th, 1887. FREDK. A. BIRD.

THE PROSPECTS OF THE PROFESSION.

To the Editors of THE LANCET.

SIRS,—It would be most desirable in the interests of parents, guardians, and aspirants to the medical profession, to place before them a plain statement of facts regarding it as a means of obtaining a livelihood. I will therefore, with your permission, proceed to discuss the subject as briefly as possible.

The lay and professional journals often contain glowing accounts of Royalty laying foundation stones, ornate presidential addresses, and allusions to peerages for the profession. The consequences are that the public are deceived, and hundreds allured to enter it when it is already disastrously overcrowded. People imagine that a youth has only to enter its portals and his future is made. Visions of baronetcies, wealth, and all its concomitant comforts float before him. The profession thus receives annually an excessive number of intending practitioners for the majority of whom the vital question will be, not whether they will refuse a knighthood or accept a baronetcy, but whether they may be able to exist.

We may assume a case which is typical of hundreds. A young man, after a cost of time and money equivalent to, say, £500, finds himself doubly qualified. How shall he dispose of his services to the best advantage? He may apply for an assistancy, which is very often most difficult to obtain. He will find hundreds with more experience and interest, possibly many with more agreeable appearance and address, so that months may elapse before he receives employment. If he be successful, he will but too often realise a miserable existence. He will possibly have plenty of responsibility, drudgery, and censure for a salary somewhat higher than that received by his employer's coachman. He may desire an appointment as a ship surgeon, and here the same conditions are almost essential to success. In the majority of cases he will be informed that they are "full up," and of the remainder no hope of immediate employment will be offered. If he be fortunate, he might receive as salary from £5 to £8 per month without any prospect of promotion.

A Poor-law appointment is almost inaccessible to a beginner. Experience, residence in the locality, interest with members of the Board, and in Ireland possibly acceptable religious and political tenets are indispensable qualifications. The income derived both from appointments and private practice in poor districts is often scarcely sufficient to provide a respectable maintenance, while the duties are harassing in the extreme. The military and naval services can only provide for a few of the best educated of the many who annually swell the Medical Register, while hospital appointments are much sought after, difficult to obtain, and are only temporary.

The subject of private practice may next be considered. It is only to be gained by prolonged individual effort or the hazardous plan of purchase. A man may travel the whole country, and in every eligible place he will find numerous opponents more experienced, better known, possibly more skilful, and already established. If he be unable to purchase a practice he must necessarily incur great expense in establishing one and supporting himself while doing so; for years may elapse before his professional income equals his expenditure. If purchase be the means selected difficulties have still to be encountered, patients may be introduced but not necessarily transferred, many circumstances often operating to alienate their patronage.

And lastly, the prospects generally are most discouraging. The profession, already fearfully overcrowded, is annually becoming more so, quackery, patent medicines, provident associations, and clubs, all on the increase, complete the list of reasons why the profession of the future will be but a gaunt and melancholy shadow of what it was in the past as regards its dignity and emoluments.—I am, Sirs, yours truly,

May 27th, 1887. PRO BONO PUBLICO.

Germist (New York).—The paper is by Manfredi, and it was recently presented to the Accademia dei Lincei by Dr. Tommasi-Crudeli, who appended to it some considerations of his own. Its exact title is "Dell' Eccedenza del Grasso nell' Alimentazione dei Micro-organisms Patogeni, come Causa di Attenuazione della loro Virulenza: Saggio di Vaccinazione contro il Carbonchio" (On the Excess of Fat in the Alimentation of Pathogenic Micro-organisms as a Cause of the Attenuation of their Virulence: an Attempt at Vaccination against Charbon).

V. (Liverpool).—We regret we cannot comply with our correspondent's request.

SHORTCOMINGS OF SOME MODERN SANITARY METHODS.

Delivered at the Anniversary Meeting of the Sanitary Institute of Great Britain on July 14th, 1887.

By G. V. POORE, M.D., F.R.C.P.

GENTLEMEN,—I have been for some years so strongly impressed with the shortcomings of one of the chief methods of modern sanitation that I felt bound, when the Council of the Sanitary Institute did me the great honour of requesting me to deliver the annual address, to choose for my subject that which was uppermost in my mind. The principal aim of sanitarians has ever been, and ever will be, the securing for the masses of the people the two chief necessities of life—pure air to breathe, pure water to drink. Whether or not we are able to secure these two necessaries depends very largely upon the method which we adopt for the treatment of putrescible refuse, and it is on this point, and on the modern fashion of mixing putrescible refuse with water, that I propose to address you.

It may be well to remind you that all dead organic matter is putrescible, and, when I speak of putrescible matter, I mean all organic matter, inclusive of excrement. Nature moves in a circle, animals feed on each other and on vegetables, vegetables feed on the dead bodies of animals and vegetables, and on the solid and gaseous excrements of animals. Animal and vegetable life are complementary, and mutually support each other. This is a law of nature, and when I make this assertion I feel I run no risk whatever of being contradicted. The laws of nature are inexorable—i.e., they are not to be set aside by human prayers—not even by that best of all prayers, labour. Those who disobey the laws of nature, or who enter into a contest with her, are sure to be worsted in the end. If we fight with nature we court calamity. I have elsewhere compared those who fight with nature to Sisyphus, who, according to the old mythology, was condemned in the lower world to a never-ending contest with the force of gravity—

> With many a weary sigh and many a groan,
> Up the high hill he heaves a huge round stone;
> The huge round stone resulting with a bound,
> Thunders impetuous down, and smokes along the ground.

By means of great expenditure of time and money, we may wage for a period with nature a war which may be apparently successful. The war can never be really successful, it will never terminate; nature in the end will assert her eternal sway, and crushing defeat must be our lot.

As the inevitable destiny of putrescible matter is to become the food of vegetables, a destiny which we can delay at the most only for a brief period, our proper course in dealing with it is clearly not to attempt to prevent or even to delay the inevitable. Such a course is to disobey the laws of nature, to fight with her, and court ultimate defeat. Our wiser plan is to help nature in her work, and thus win her smiles. It has been the wise custom in all ages of the world to dispose of putrescible matter by burial in the earth. Dead bodies have in all ages been buried, and the greatest of all lawgivers and sanitarians, Moses, whose likeness rightly takes the place of honour in this room, gave most explicit directions that excremental matters should be treated in the same way. This is a not unimportant fact, and although we do not in this country follow the whole of the Mosaic law, nevertheless that law is so pregnant with marvellous wisdom that we ought not to discard any item of it without first questioning ourselves most strictly as to our unwillingness in so doing. The latest advances of modern science seem to show that in this particular Moses was absolutely in the right.

It has been shown, I think, conclusively that the decomposition of organic matter, whether in the earth, air, or water, is brought about by minute fungoid organisms, the growth of which has the effect of resolving the highly complex organic compounds into solid debris or gaseous bodies, which can be absorbed by the roots of plants. Now, when putrescible matter is buried in the earth, it undergoes decomposition without the occurrence of putrefaction—that process which is at once offensive to the senses and dangerous to health. This is effected by means, mainly it is supposed, of mould fungi, which produce oxidation of the organic bodies. If sufficient air has access to the pores of the soil, and if sufficient moisture be present, the nitrogen takes oxygen to form nitric acid, which, combining with the bases, forms soluble nitrates, and the carbon also combining with the oxygen forms carbonic acid, which, combining with the bases, forms carbonates. The best account which I have been able to find of the active organisms which are ever present in the soil is in a paper by Professor Wollny[1] of Munich, which was brought to my knowledge by my friend, Dr. E. F. Willoughby. These organisms are so incalculably numerous that their activity must be exceedingly widespread. Koch found enormous quantities, even in winter, in the soil not only of crowded places like Berlin, but in that also of remote fields. At the observatory of Mount Souris 750,000 were found in a gramme of earth, and at Genevilliers from 850 to 900,000.

If the action of the microbes be checked by antiseptics, the vapour of chloroform, or heat (100° C.), the chemical changes in the earth cease. That the formation of nitrates and carbonic acid from organic matter in earth to which air has access is due to microbes has been proved by direct experiment. When, however, organic matter is mixed with earth, and air is admitted in sufficient quantity or entirely excluded, the decomposition is of another kind; and, besides small quantities of carbonic acid and carburetted hydrogen, there is formed water, ammonia, free nitrogen, and a great quantity of a black carbonaceous peat-like matter (the so-called sour humus). Schlösing found that the nitric acid in the soil disappeared when the air was replaced by nitrogen. The kind of organism seems to vary with circumstances. As long as air is freely admitted, the mould-fungi (*Schimmelpilze*) preponderate; and when air is excluded, the schizomycetes (*Spaltpilze*) increase. The formation of nitric acid in organic earth mixtures depends on the amount of oxygen which is present in the air admitted. Thus Schlösing found by experiment that the formation of nitric acid varies as under:—

	Per cent.				
Oxygen	1·5	6	11	16	21
	Milligrammes.				
Nitric acid...	45·7	95·7	132·5	246·6	162·6

The nitrification which took place with a limited supply of oxygen was due probably to the air already mixed with the earth before the experiment began.

Millor and Boussingault have shown that no nitrification takes place in thoroughly soaked earth to which little air has access, and that when oxygen is absent the nitrates in the earth are reduced. The formation of carbonic acid also depends upon the admission of air (containing free oxygen), but some carbonic acid is formed even though all air be excluded.

	Per cent.			
Oxygen in air	6	11	18	21
	Milligrammes.			
	Pure N.			
Carbonic acid	9·3	15·9	16	16·6	16

Nitrification is assisted by a moderate amount of moisture. It attains its maximum when the moisture reaches 33 per cent., and above and below this the process of nitrification and formation of carbonic acid is hindered. Temperature has a great influence on oxidation in the earth. It reaches a maximum, with a temperature of about 50° C. (120° F.), and stops at 55°. Oxidation goes on most quickly in the dark.

Thus, oxidation depends not only on the presence of the organisms, but also on the presence of other factors, such as suitable aeration, suitable moisture, suitable temperature. These factors may all be suitable, or some may suit and others may not suit the oxidation process. The decomposition of organic matter in the soil is governed by that factor which is at its minimum.

The process of decomposition is much influenced by the physical condition of the soil, as, e.g.—(*a*) permeability for

[1] Ueber die Thätigkeit niederer Organismen im Boden: Deutsche Vierteljahrschrift für öffentliche Gesundheitspflege, vol. xv., 1883, p. 705.

Digitized by Google

air and water, (*b*) nature and permeability of subsoil, (*c*) slope, (*d*) aspect, (*e*) warmth dependent on aspect, mineral composition, colour and moisture and nature of the crop. Barren soils are warm, while those covered with green crops are cool. That the variations of the ground water have a bearing on the oxidation processes cannot be doubted, when we reflect that the soaking of the upper layers of the earth is much influenced by the height of the ground water. When all the layers of earth are soaked, putrefactive processes, through the medium of schizomycetes, take place. When the ground water falls, and the air again enters the pores of the soil, the growth of those organisms is favoured which assist in the oxidation of the soil. All changes which organic matter undergoes in the earth are thus seen to be brought about, almost exclusively, by the life of lower organisms, the activity of which is ruled by the same natural laws which govern the growth of higher plants. There can be no better illustration of the true economy of nature than this action of the microbes in the soil on the conversion of organic matter into soluble salts and gases which serve as food for plants.

The growth of the microbes depends upon the concurrence of those conditions which by experience we all know to be favourable to the growth of higher plants. There must be a good supply of free oxygen, sufficient, but not too much, moisture, and a summer temperature. In well-tilled ground, broken up so as to admit air to its pores, and in a "fine growing season," in which sunshine alternates with showers, this process of oxidation is at its maximum. The microbes are active beneath the surface, manufacturing plant food from organic matter, and the favourable conditions above soil and below cause a vigorous growth of crops. When, on the other hand, the weather is unfavourable, and when, in consequence of excessive cold, excessive drought, or excessive wet, crops are not developed as they should be, the microbial life is also checked, and the change of the organic matter is delayed, and it is stored up for future use in more favourable seasons. This is the explanation apparently of the fact well known to farmers, that the effect of organic manures is more permanent than that of the so-called artificial manures which at present are so much in vogue. The organic manure remains entangled in the soil, and is not readily washed out of it in winter when the temperature is low, or even in unpropitious summers. It cannot be washed out until microbial growth has changed it into soluble salts; and when this change takes place, which it does in "good" weather, the roots of the growing plants seize hold of the ever-forming soluble salts and appropriate them to their own use. In fact, the farmer who uses organic manures, from the farmyard or elsewhere, need trouble himself very little with agricultural chemistry or experiment. He may feel certain that if he buries his organic manure *directly it is produced*, it will not be wasted. It will not give off ammonia to the air, nor will the juices be washed away by rain to the same extent as when it is left above ground to be a nuisance. There seems to be no doubt whatever that all heaps of manurial matter which give off ammonia and other gases to poison the air, and perhaps do more serious mischief which we "know not of," are allowing valuable matter to escape, which ought to be undergoing oxidation in the earth. There can be no doubt whatever that to the agriculturist stink means waste; and it is to be hoped that when the bucolic mind has imbibed this great and important truth, the country will be more evenly pleasant than it is.

The reason why farmers allow putrescible matter to fester in heaps appears to be, (1) that the matter has to wait until land is clear and circumstances permit of its being dragged to the fields; and (2) that when the matter is thoroughly rotten and most offensive, a more rapid and visible result is produced, notwithstanding that the total result is probably less than if the matter had been applied to the ground at once. It is certain that putrescible matter intended for manure must waste more above ground than when buried immediately beneath it. Rich farmers are now building sheds over their yards to prevent the access of rain to the manure, and are providing tanks for the reception of liquid which drains away. This involves a very great expense, and it is at least doubtful whether the result is better than that got by the immediate application of such matters to the soil—a process which involves no extra expenditure of any kind,—a most important matter, because the only acceptable test of good husbandry is the balance sheet. Mr. Warington, F.R.S., in his valuable little book on "The Chemistry of the Farm," says: "The most complet return to the land would be accomplished by manuring i with the excrements of the men and animals consuming th crops" (p. 28); and again, "Farmyard manure is a 'general manure; that is it supplies all the essential elements of plan food. ..... The effect of farmyard manure is spread over considerable number of years, its nitrogen being chiefl present, not as ammonia, but in the form of carbonaceou compounds, which decompose but slowly in the soil." Th immediate return is often less than when artificial manur consisting of soluble nitrates and phosphates, is used; bu the important point seems to be that the return is tolerabl sure to come in the long run.

The late Prof. Voelcker, in the article "Manure" in th Encyclopædia Britannica, gives an interesting table of th experiments of Sir John Lawes and Dr. Gilbert, spreadin over a period of twenty-four years, in which is shown th effect of different manures on crops. The most successfu results with artificial manure were got by applying nearl 1400 lb. weight per acre of mixed ammonia salts, super phosphate, and sulphates (potash, soda, and magnesia With this manure there was an average production o 37½ bushels of wheat, weighing on an average 59 lb. pe bushel, and multiplying these two figures together we ma say that the production of wheat averaged 2212·5 lb. Th production of barley averaged 41½ bushels, weighing 53⅜ lb and multiplying these figures we may say that the averag production was 2588 lb. Where the land was manured wit fourteen tons of farmyard manure the average production o wheat was 35½ bushels, weighing 60 lb., giving a figure o 2115 lb., and of barley 48⅜ bushels, weighing 54⅜ lb., givin a figure of 2650 lb.

Thus farmyard manure, when used for wheat growing gave a yield of 97 lb. less than when the best artificia manure was used, and when used for barley growing i gave 62 lb. more than when artificial manure was used These figures are certainly not such as should discourag us in the use of farmyard manure, especially when w remember that the average agriculturist is not likely t apply his artificial manures with the knowledge and judg ment of Messrs. Lawes and Gilbert, and that in the use o farmyard manure it is not easy for him to go very wrong Again, farmyard manure is stuff which *must* be used, whil chemicals are things which *must* be bought, and need to b analysed when bought.

It is a great mistake to suppose that farming is in an way comparable to a chemical experiment. In experiment conducted in the laboratory the chemist is able to contro *all* the conditions of the experiment; but in farming th condition which above all others influences the result viz., the weather—cannot be controlled. When chemica manures are used with judgment and applied at the righ moment, and when the weather is favourable, there is n doubt that the result is often surprising and gratifying. Whe however, the weather is unfavourable, when the drought so great that the chemicals cannot be dissolved, or when th rain is so heavy that they are washed out of the soil, th result is not encouraging. If organic manures are used, the do not waste in bad seasons, and much remains in the groun for next year's crop. The farmer, however, who appli chemicals in a bad season gets neither crop nor residuum manure for next year. Mr. Warington says that "farme have a prejudice in favour of the latter (i.e., organi manures, but it is clear that the quickest return for capit invested is afforded by the former class" (i.e., inorganic Surely we have no right to blame the farmers for their pr judice, which seems to be in all respects reasonable. Th doctrine has obtained in this country of late years that it good economy to waste all our home-grown organic manur and to import chemicals from South America for the purpos of agriculture. This is a strange doctrine; but as most our farmers are now too near bankruptcy to pursue th course, we may hope that ere long they will begin to clamo for that which we now waste so wickedly.

One more word before I bring my remarks on farming a close—remarks for which I make no apology, for I fe sure you must already recognise their bearing on the subje of sanitation. The remark I have to make is this, that the hands of Lawes and Gilbert farmyard manure ga better results with barley than with wheat. May not th fact that farm animals are largely fed with barley meal ha something to do with this? There are experiments whi show that minimal ingredients in manures are not witho effects which are often surprising. There are *a pric*

Digitized by Google

grounds for thinking that the best manure for barley must be the excrement of a barley-eating animal, for in that excrement must be all that is necessary for barley. I wish some agriculturist would make the experiment of growing wheat with the excrement of a wheat-eating or bread-eating animal. As a gardener I have grown potatoes with the excrement of a potato-eating animal, and certainly the result has been most encouraging.

I have been obliged to draw my illustrations as to the practical result of burying organic matter from the agricultural employment of farmyard manure, because facts based upon exact experiments with the organic refuse of our towns is not forthcoming. *What I want to insist upon is this, that the proper destiny of organic refuse is immediate burial just below the surface of the soil.*

Most of the shortcomings of modern sanitary methods are due to the fact that in our dealing with organic refuse we commit a scientific error—i.e., we pursue a course which is in opposition to natural law. This error consists in mixing organic refuse with water. When organic refuse is mixed with water, it undergoes changes which differ widely from the changes which it undergoes when mixed with earth. According to Wollny, whose paper I have quoted previously, the process of oxidation of organic matter and the formation of nitrate takes place most readily when a moderate amount of moisture is present. The most favourable amount is about 33 per cent., and if the moisture rise above or sink below this amount, the process of nitrification and the formation of carbonic acid is hindered. When water is in excess the amount of free oxygen is insufficient to favour the growth of mould fungi, the schizomycetes (bacteria and micrococci) are formed, and, in place of oxidation, putrefaction occurs, with the formation of ammonia, free nitrogen, carbonic acid, and carburetted hydrogen. Under these unfavourable circumstances it is possible that the nitrates which may have been formed may be again reduced. This process of deoxidation takes place in mixtures of putrescible matter with water, and takes place also, it is said, in soil which is thoroughly soaked with sewage—i.e., putrescible matter mixed with water. In the face of these facts it is not to be wondered at that "sewage farming," which is farming under acknowledged difficulties, has not proved a commercial success. We must indeed be in doubt whether, when the circumstances are more than usually unfavourable, it exercises any very great purifying action upon the putrescible mixture. In the treatment of putrescible refuse, so that it shall not be a danger or annoyance, what we have to aim at is nitrification rather than putrefaction, and it is certain that by mixing with water putrefaction is encouraged and nitrification delayed.

It seems to be almost incontestable that the proper course to pursue with regard to organic refuse—putrescible matter—is the very reverse of that which we do pursue. We clearly ought to encourage oxidation and make putrefaction impossible. Putrefaction is certainly a great cause of ill-health. It was the putrefaction of wounds (now, happily, almost unknown) which converted our hospitals into something little better than charnel-houses. It is the putrefaction of organic refuse mixed with water in cesspools and sewers that causes that long list of ailments which we ascribe to the inhalation of sewer air. The opinion is held by many that the dejecta of typhoid patients and cholera patients do not become dangerous to others until putrefaction has set in, and such an acute observer as was the late Dr. Murchison held the opinion that common putrefactive changes taking place in dejecta were a sufficient cause of typhoid, independently of the admixture of any specific poison.

The putrefaction of organic refuse, when mixed with water, has, I think, been the chief cause of the development of modern sanitary "progress." Our forefathers were not given to this method of treating putrescible matter. House-slops trickled along open gutters, and excremental matters were deposited in dry pits. At the beginning of this century the watercloset came into use. Mr. W. Haywood, quoted by Dr. Farr, says, "Watercloset were invented about 1813, and became general in the better class of houses about 1828-33. The custom at first obtained of building cesspools having overflow drains put below their doming, by which means the solid matters were retained and the supernatant liquid only ran off. In the year 1849 what may be said to be an organic change in the system took place. In 1848 the City Commission of Sewers obtained its Act for sanitary purposes, which became operative on Jan. 1st, 1849, and then for the first time was discharge into the sewers legalised. Previously a penalty might have been enforced for such a usage of them, but henceforth, within the City of London, those incurred a penalty who failed, upon notice, to construct the drainage of premises in such a manner as not to discharge all waste waters *and fæcal matters directly into the public sewers* [i.e., directly into the sources of water supply], of which the full utility was, therefore, for the first time recognised by statute. This Act was speedily followed by others for the remaining area of the metropolis and for the entire country." "It will be noticed," says Dr. Farr, "that the deaths from cholera and diarrhœa increased in London in 1842, increased still more in 1846, when the potato crop was blighted, and in 1849 culminated in the epidemic of cholera." Dr. Farr says further, "a system of sewerage is the necessary complement of a water-supply. ..... Almost coincidently with the first appearance of epidemic cholera, and with the striking increase of diarrhœa in England, was the introduction into general use of the watercloset system, which had the advantage of carrying night soil out of the houses, but the incidental and not necessary disadvantage of discharging it into the rivers from which the water supply was drawn."

Mortality per 1000 from diarrhœa in London (Dr. Farr).

1838	·215	1853	1·011
1839	·201	1854	1·257
1840	·238	1855	·804
1841	·238	1856	·866
1842	·353	1857	1·181
1843	·410	1858	·759
1844	·340	1859	1·211
1845	·397	1860	·496
1846	·997	1861	·928
1847	·898	1862	·607
1848	·853	1863	·821
1849	1·705	1864	·981
1850	·813	1865	1·206
1851	1·085	1866	1·306
1852	·983	1871-80—Dr. Ogle	·940

Thus in the decade 1871-80, 33,168 persons died of diarrhœa in London, the death-rate from this cause being ·94. If the death-rate of 1838 (·215) had obtained in the decade 1871-80, the deaths from this cause would have numbered only 7600, and there would have been a saving of 25,568 lives.

Since the introduction of the watercloset, and I believe as a direct consequence of it, we have had four severe epidemics of cholera (a disease not previously known), and enteric or typhoid fever (previously almost or quite unrecognised) has risen to the place of first importance among fevers in this country. The evils which have arisen from cesspools and sewers have caused an enormous amount of attention to be devoted to what are known as "sanitary appliances," sewer constructions, &c., and so great and so well recognised are the evils of sewers that many of our friends are anxious that we should be compelled by Act of Parliament to protect ourselves from the mischief which previous Acts of Parliament have produced.

Not only does the putrefaction of organic refuse tend to fill the air of our houses and towns with foulness, but this mixture of organic matter with water is attended with other bad consequences. This arises from the fact that much of the organic matter which we mix with water is distinctly poisonous. The zymotic theory of disease has of late years assumed more definite shape, so that we may now leave what was called the zymotic theory and consider the actual facts. There is no doubt that the actual infective elements of many zymotic maladies consist of microbes, fungoid bodies belonging to the class of fungi known as schizomycetes, that class which grows in organic mixtures where insufficient free oxygen is present. These microbes are infinitely small; millions of them may live in a cubic inch of putrefying liquid. Under favourable circumstances they will live for long periods. They will not only live, but multiply, and it is at least a question, and a grave one, to what extent these infective germs undergo an increase when mixed with organic liquids such as sewage or milk.

The fact that the zymotic poisons are *particulate and alive* is one which has most important bearings on the subject under discussion. If the poison were a chemical poison, then dilution would practically do away with its power for harm. No amount of dilution is capable of destroying a zymotic poison; in fact, it is not impossible

Digitized by Google

that the mere mixing of organic refuse which contains a zymotic poison with water may be the means of keeping it alive, and possibly causing it to multiply. When a mass of organic matter, charged with zymotic particles, is mixed with water and washed out of a house, the water will carry the poison with it wherever it may chance to flow or trickle, to watercourse, well, or any other source of drinking water; in fact, the dissemination is as perfectly and thoroughly done as if dissemination of poison were the main object which we had in view. When dealing with organic matter impregnated with zymotic poisons, mere dilution with water increases rather than diminishes the danger. As long as the poisonous organic refuse is concentrated, its repellent qualities are such that there is little chance of its gaining access to the human body. The microbes contained in it are theoretically capable of infecting an almost indefinite quantity of water, and this large quantity of water masks the repellent qualities of the stuff, and thus the danger of infection is greatly increased.

This dissemination of poison by water is one of which we have had very bitter experience in this country. There is little room for doubt that, in this country at least, water has been the great carrier and disseminator of the poison of cholera. In 1849 the mortality was highest in those districts getting their water-supply from the Thames between Battersea and Waterloo Bridge. In 1853-54 the same phenomena were observed. In 1866 the chief mortality was in the district supplied with water taken from the river Lea. With regard to this latter epidemic we are in possession of many details, and the following is a summary of the facts, as given by the late Dr. William Farr in his report on the cholera epidemic of 1866:—"Several cases of cholera and choleraic diarrhœa had occurred over London in May; and on June 27th, at 12, Priory-street, Bromley, one poor Hedges, a labourer, and his wife, both of the age of forty-six years, died of 'cholera Asiatica,' the former after fifteen, the latter after twelve hours' illness. These cases are minutely described by Mr. Radcliffe, who traces the discharges into a water-closet of 12, Priory-street, and thence 300 yards down the sewer into the Lea (a tidal river which ebbs and flows) at Bow Bridge, half a mile below the Old Ford reservoirs. He attaches great importance to these first cases, and they undoubtedly sufficed to pour into the sewers and waters millions of zymotic molecules, which day by day grew more and more frequent in the Lea by every hour's choleraic discharges on both sides of the river." A few days later water was supplied to the district from a reservoir, the bottom of which was pervious to the waters of the Lea, and then resulted an outbreak of cholera and diarrhœa which resulted in the death of over 4000 persons.

I need not give further instances of the dissemination of disease by water-carried sewage; sanitary literature is full of them. What is true of cholera is also true of typhoid, and I will only say in reference to this subject that (if we accept, as we are bound to do, the statements put forward with regard to the cholera epidemic of 1866) if the excreta of the Hedges' family had been buried or burnt, the waters of the Lea would not have been infected, and possibly 4000 lives would have been saved.

The first principle in dealing with epidemic disease is that which is expressed in the words *Principiis obsta* (Resist the beginnings). The object of this is evident, and is well expressed by Shakspeare in the words—

> "A little fire is quickly trodden out,
> Which, being suffered, rivers cannot quench."

The mixing with water may be looked upon certainly not as a resistance of the beginnings, but rather as a nursing and favouring of them, which, "being suffered," most certainly "rivers cannot quench." The great principle of *principiis obsta* has been most rigidly observed by surgeons in dealing with those forms of blood poisoning which arise in connexion with wounds, and which were known as hospital diseases. To Lister belongs the credit of recognising that the great thing to be aimed at was the checking of putrefactive changes in the discharges from the wound, an end which has been attained by adopting what are known as antiseptic precautions in the treatment and dressing of wounds. A foul wound is looked upon as a great source of danger to the patient himself, and formerly the poisons generated in the wound of one patient were carried by sponges and instruments (which, be it remembered, were *clean* as far as any indications appreciable by our unaided senses were concerned) to the wounds of others; and thus it followed that the mortality from what was wrongly spoken of as "hospitalism" was enormous. Now, however, putrefaction in wounds is practically at an end, owing to the use of antiseptics and to an improved appreciation of what cleanliness really means; and, as a result of this, hospitalism has disappeared.

How marvellous have been the results which have followed on the adoption of the principle of preventing putrefaction in wounds is well shown in a table given in the last edition of "Erichsen's Surgery." This table is taken from a statistical work by Max Schede on amputations, and shows conclusively what are the advantages of antiseptic precautions. I have simplified his statement for the sake of those of my audience who are not acquainted with medicine.

Uncomplicated Cases of Amputation.

Cause of death.	Old treatment, 377 cases.	Antiseptic treatment, 321 cases.
Blood poisoning.....	105	3

Thus it appears that the mortality from blood poisoning under the old treatment was 28 per cent., while under antiseptic precautions it is less than 1 per cent. Antiseptic measures are used in other than purely surgical cases, and my friend, Dr. John Williams, tells me that since their introduction into the General Lying-in Hospital the deaths from that terrible disease "puerperal fever" have practically ceased. This great result has been brought about by attention to the leading principle of *principiis obsta*. In my student days the treatment most in vogue for wounds was "pure" water; but now it is recognised that water is preeminently the encourager, and sometimes the main cause, of putrefaction, which of all things the surgeon tries to avoid.

The foulness of our rivers is largely due to the mixing of putrescible matter with water—i.e., to water-carried sewage; and there can be no doubt that as water-carried sewage increases, the difficulty of obtaining pure water increases also. Water-carried sewage so fouled the Thames "between the bridges," that after the bitter experiences of 1854, the intake of the water companies was moved to a point above the tideway. Since then the population all along the Thames valley has enormously increased, and if we who get our drinking water from the Thames escape disease, it can only be regarded as due to a happy accident, and not to the observance of any fixed principle to effectually prevent the fouling of the river. The precious liquid with which I am supplied from the Thames costs me, I think, nearly 10*s.* per 1000 gallons, and I need not say that I am very careful to have every drop which is used for drinking purposes both boiled and filtered.

If sewage finds its way to a water source, I have not much faith in the various modes of "treatment" which it undergoes in those establishments which local boards love to erect for this expensive amusement. The addition of chemicals, if in sufficient quantity to destroy living organisms, must make the water still more unpotable than before, and can only be of use by making the liquid so utterly nauseous that to drink it would be impossible. Mere filtration cannot be regarded as any safeguard after the experience of the Lausen typhoid epidemic, in which the poison of the fever filtered through a mile of earth, which was sufficient to check the passage of particles of wheat flour. Wide irrigation over a large area of land, as is practised in "sewage farming," is probably the best method of treating sewage, but this cannot be regarded as absolutely safe under all conditions, for reasons previously indicated. If antiseptics have been previously added to the sewage this must increase the difficulties of "farming" with it; as, if the antiseptics have been added in sufficient quantity to destroy disease organisms, this would effectually check the growth of those organisms upon which the fertility of the soil depends.

It is more than doubtful whether there is any absolute safety in obtaining water from deep wells. The Dudlow-lane well, near Liverpool, having a total depth of 443 feet, was fouled by percolation from cesspools, and percolation from a defective sewer would certainly prove equally disastrous. Surface wells are now not regarded as at all safe, but our suspicions with regard to them were not aroused until after the introduction of the plan of mixing water with putrescible matter. There was no soakage from an old-fashioned dry pit. There must be soakage from a cesspool or "dead well." The only way of securing pure water is to make quite sure that there is no fouling of water sources. If this were done, then pure water would be at

Digitized by Google

once plentiful and cheap. It is now very dear, and is getting scarcer every day. Dr. Wm. Farr said, "a system of sewerage is the necessary complement of a water supply." For myself I should be inclined to say that an extraordinary water supply is the necessary complement of water-carried sewage, because with it our ordinary supplies quickly get fouled. In London we have effectually fouled all our wells, and the state of the Thames is such that a man must be in the very extremities of thirst, or else insane, before he would drink from the Thames anywhere between Teddington Lock and Gravesend. The state of our noble river is a deep reproach to us, and must remind us day by day of the serious blunders we have committed. As long as it remains as it is we certainly have no claim to be followed as an example in matters sanitary. London should serve as a warning, as did the drunken helot to the Spartan youth.

The fouling of our sources of water supply has driven us far afield for water, and this no doubt has been a great cause of the lessening of our mortality of late years; but it would be unwise to talk of security because we have had no serious epidemic since 1866, an absurdly short period in the history of a nation. It must not be forgotten that pure water is as necessary for animals as it is for man, and that if we persist in fouling our rivers the poor farmer may have to pay a "water rate" for providing an artificial water supply for his horses, cattle, sheep, and even poultry. Many diseases of animals are communicable to man, and it is daily becoming more evident that our health is very intimately bound up with the health of our animals, and that their sanitary condition is scarcely less important than our own.

From a financial point of view, water-carried sewage has not been encouraging. It has increased the rates, increased the cost of our houses, and put us to great expense for water. The "treatment" of sewage before it is finally discharged into our rivers is everywhere an expense and nowhere a source of profit, and we find that public sewers which cost millions, cost thousands to keep them in repair. The sewers we have built with borrowed capital. We have seized all the glory and patronage of disbursing enormous sums, and have left posterity to pay the bills. This is a doubtful policy, and I think a most immoral one; but I feel it is little use to raise my feeble voice against the custom, which is now so much encouraged, of hanging a debt round the neck of our successors. It may be defensible to raise a loan for building town halls, schools, and similar edifices, of which posterity will reap the benefit; but to raise loans for the purpose of wasting most valuable fertilising matter by means of works which will be a constant expense, and never a source of profit, is a very doubtful expedient. I hope the custom will soon obtain of compelling each generation to bear the charge of its own sanitary experiments—and blunders.

Sewers are constant sources of impoverishment to the soil, and the soil, be it remembered, is the only *permanent* and reliable source of wealth in any country. The waste of valuable matter which takes place in London and our big towns must make us blush. I wish the waste were limited to our big towns, but it is not so. It is common throughout the country, even in rural districts. Free trade has made food very cheap indeed, and cheap food, especially *imported* food, ought absolutely to increase the fertility of a country, for obvious reasons which I need not particularise. The fertility of this country is not increasing, to judge by the agricultural distress. The farmers are crying out for "protection." The first kind of protection needed seems to me to be a protection from ourselves and from the sinful waste of fertilising matters which local boards, municipalities, and Imperial Parliament equally foster. If we made a proper use of our organic refuse we should enrich posterity. As it is, we reap and we do not sow. If municipalities would bury organic refuse, and plant the seed of some forest tree suited to the soil and situation (which in these days of cheap food stuffs would probably be the best branch of agriculture to pursue), they would earn the blessings, instead of the curses, of posterity; and they would beautify the face of nature, instead of making it hideous with tall chimneys, pumping stations, and precipitating tanks. This piece of advice will, I fear, fall very flat, for of all agricultural arts, forestry seems the deadest in this country.

As a defence for gigantic sewage schemes, it is often said that you can do nothing well without co-operation, and this is the excuse for compelling all, whether they want them or not, to contribute towards the cost of sewers. If co-operation be for a good end, the result is a great good; but if co-operation be for a bad purpose, the result is a great evil. I need say no more.

The last charge which I have to bring against water-carried sewage is a serious one—viz., that it encourages overcrowding in cities, which is universally admitted to be the greatest of all sanitary evils, and one which cannot be counterbalanced. Water-carried sewage encourages overcrowding, because it enables us to build houses with no outlet except a hole for the sewage to run through. The growth of London must be a source of alarm to sanitarians, and it is impossible not to admit that our system of sewers has been a most important factor in its production. Look at Charing-cross, where a street of gigantic clubs and hotels has arisen, each without curtilage of any kind, and where a handsome profit has been made by setting the first law of sanitation at defiance. You will find the same thing to a greater or less extent throughout the metropolitan area. It is difficult to say why we are so prone to crowd into cities. In former days we crowded behind walls as a protection from our enemies. Those days are at an end, but the crowding is greater than ever. The common cant of the day is that in this nineteeth century we have annihilated time and space. Certainly in cities both are excessively precious. The telegraph, the telephone, and the steam engine ought to have diminished overcrowding, but they have not. The stream is still mainly from the country towards the town, the attraction being the making of money and the spending of it.

It may be well to glance at the effect of this overcrowding in this city. It is a common remark that London is a very healthy city, and as a proof of this assertion persons point to the death-rate, which certainly of late has not been excessive. The London of the Registrar-General, however, is a very extensive place, and many of the outlying parts are almost rural in character, so that if you want to find the effect of living in a crowded city it is not fair to take London as a whole. I am no believer in the healthiness of London. It is true that our death-rate has not been raised by any great epidemic of late years, but London is undoubtedly a city where an abundance of second-rate health exists. The crowds that throng the doors of hospitals increase, and in my profession there is a great outcry about "hospital abuse"—which means, I take it, that decent folk are not able to cope with the amount of chronic disorders with which they are beset. Again, the mobility of the population in the present day makes our vital statistics very uncertain. Many a healthy person is imported into London, and, being wounded in the battle of life, returns to the country to die or recover as the case may be. There is a scarcity of very young and very old people, and in order to appreciate the vital statistics of London great allowances have to be made for the abnormal age distributions.

In order to judge of the effect of overcrowding, let us look at the vital statistics of the Strand Registration District, which is about the centre of London, and from which one would have to walk very many miles to reach the country in any direction. The Strand enjoys many advantages. It is mainly a wealthy district, extending in irregular form from Temple Bar to Buckingham Palace. It includes the whole of the Green Park and half St. James's Park. It has a gravel soil, and slopes gently, with exposure to the south, to the fringe of (potentially) the noblest river in the country. The worst and poorest parts are at the north-east corner. I have compiled a table from the last nine quarter-year tables which have appeared in the *British Medical Journal*, so that I am able to compare the Strand with the whole of London (for nine quarters) and with Dorset (for ten years, 1871-80).

——	Birth-rate.	Death-rate.	Zymotic death-rate.	Deaths under 1 year to 100 births.
London	32·5	19·9	2·7	151
Strand and St. Martin's-in-the-Fields	23·7	21·8	2·6	192
Dorset (10 years 1871-80) ...	20·53	17·46	1·68	108

I have chosen the county of Dorset for comparison because it is a "healthy district," and if we are to do any good we must always aim at a high standard. Again, the Dorset-

shire labourer has always been a favourite stalking-horse for cockney politicians, and it may be well to show how much healthier he is than the Londoner, notwithstanding his supposed condition of chronic starvation. This table is very interesting. Dr. Letheby said, "A high death-rate means a high birth-rate, and a high birth-rate is the invariable concomitant of prosperity." This dictum does not evidently apply to the Strand. Dr. Farr, on the other hand, pointed out that "a low birth-rate implies a small proportion of young adults and a large proportion of the aged." This dictum, again, does not apply to the Strand, as we shall see by a reference to the next table, in which I have endeavoured to make corrections for the abnormal age distribution which obtains in that district, and which Dr. W. Ogle rightly insists is absolutely necessary before you can arrive at just conclusions.

The Strand. Mean population 1871-80 = 37,461.

Ages.	Actual numbers living at each age.	Normal age distribution for a population of 37,500.	Difference (+ and −) between actual and "normal" numbers.	Actual deaths in 10 years, 1871–80.	Deaths which would have happened had the distribution of ages been normal.	Death-rate at different ages.	Death-rate of Dorset.	Deaths which would have happened had the death-rate of Dorset obtained in the Strand.
Under 5	3597	5100	−1503	3596	5100	99·97	40·07	1440
5—10	3134	4500	−1366	390	548	12·44	4·31	129
10—15	3069	4012	− 943	163	212	5·31	2·79	84
15—20	3824	3640	+ 190	317	299	8·29	4·43	167
20—25	4426	3337	+1089	366	273	8·27	6·65	290
25—35	6773	5512	+1261	963	770	14·22	7·50	510
35—45	5121	4237	+ 884	1246	1009	24·33	10·48	525
45—55	3935	3225	+ 710	1338	1088	34·00	13·04	520
55—65	2311	2212	+ 99	1147	1100	49·63	24·56	565
65—75	1003	1237	− 234	754	900	75·17	55·28	550
75 & over	268	487	− 219	425	774	158·58	151·71	403
	37461	37500		10705	12074			5203

From this table it appears that there was in the Strand during the decade 1871-80 a deficit of 3812 children under fifteen, and of 453 of persons over sixty-five, while there was a surplus of 4233 persons between fifteen and sixty-five. This abnormal distribution ought, according to Dr. Farr, to give us a high birth-rate and a low death-rate. The very reverse is the case, and a critical examination of the figures seems to show that the death-rate in the Strand *is more than double what it is in Dorsetshire.* It may be said that this high death-rate is due to the presence in the Strand of two hospitals (Charing-cross and King's College), and doubtless these have some material effect in producing the terrible adult mortality. Hospitals, however, are generally placed where they are most needed, and I would point out that these institutions can hardly account for the enormous infant mortality; and certainly not for the deaths of infants under one year. Against the fact that the Strand contains two hospitals is to be placed the not less important fact that it contains no workhouse. This institution is at Edmonton, where it helped to raise the death-rate from 15·8 to 16·9.

It need not surprise us that a population situated in the very centre of the vastest city the world has ever seen should have a high death-rate, and it may be well to look to the causes of death and again to compare the rates from different causes with those in Dorsetshire.

Death-rate from different causes.

	Strand.	Dorsetshire.
Whooping-cough	0·62	0·29
Tabes	0·28	0·18
Phthisis	3·65	1·72
Hydrocephalus	0·61	0·22
Respiratory disease	5·92	3·15
Total of tubere. and resp. disease	11·08	5·56
Small-pox	0·11	0·09
Measles	0·36	0·20
Scarlet fever	0·49	0·33
Enteric	0·38	0·19
Violence	1·61	0·49
Diarrhœa	0·92	0·35

No good would be got by extending this table. Suffice it to say that there is no single cause of death in the Registrar-General's tables which is not more active in the Strand than it is in Dorsetshire. I would particularly draw attention to the fact that the death-rate for whooping-cough and tubercular and respiratory disease for the Strand is more than double that of Dorsetshire—a fact which is not to be wondered at in a population the bulk of whom only breathe pure air upon the rarest occasions, and who habitually breathe an air so foul that the sun often fails to penetrate it, and which is fatal to almost all flowers and a large proportion of trees. To me one of the saddest indications of the dismal state of this overgrown city is the appeal, which is now so common in the newspapers, for funds to give poor London children *one* day in the country, with of course the not immaterial deduction of the hours spent in going and returning.

These tables may serve to dispel another popular fallacy—viz., that the sulphur-laden air of London has antiseptic powers, and helps to check zymotic disease. As a fact, those zymotic diseases which presumably travel through the air (small-pox, whooping-cough, and measles) are particularly rife in London. The death-rate from these three causes was during 1871-80—

	In London.	Dorsetshire.
Small-pox	0·44	0·09
Measles	0·51	0·20
Whooping-cough	0·81	0·29
	1·76	0·58

In fact, the mortality caused probably by air-borne germs was exactly three times as great in London as in the healthy country district which I have chosen for comparison.

I have endeavoured to show that the admixture of water with putrescible matter is inadmissible—(1) because it is antagonistic to a law of nature, and there can be no successful antagonism to nature; (2) because the putrefaction set up in cesspools and sewers by mixing water with putrescible matter has been a direct cause of much disease; (3) because the practice involves the most perfect dissemination of disease particles, and involves a neglect of the great principle *principiis obsta;* (4) because it is the great cause of the fouling of rivers and wells, and makes the obtaining of pure water increasingly difficult; (5) because it is financially and economically disastrous, crippling the ratepayers, and exhausting the land; (6) because it is one of the chief causes of overcrowding, the greatest of all sanitary evils.

It may be asked, "What useful purpose can be served by talking thus to an audience of Londoners? London is hopelessly committed to the principle of water-carried sewage, and must make the best of it." To this I reply that even London need not needlessly increase her already insurmountable difficulties, and that happily the whole of England is not yet quite absorbed into London and other cities. There is a very general belief throughout the country that because London has adopted the system of water carriage it must therefore be the best. This idea is unthinkingly adopted, and to its adoption the distinction

Digitized by Google

of borrowing and disbursing a large amount of other people's money acts as a spur. There has come within my own knowledge the case of a country town, in the midst of a poor agricultural district, which clamoured for a "sewage scheme" for the purpose of polluting its sparkling watercourse, where anglers pay large sums for the privilege of trout-fishing, its death-rate being at the time between 16 and 17 per 1000. In the Thames valley, the region of villas and market gardens, a whole crop of "sewage schemes" has lately been put forward, notwithstanding that the more rational methods of sanitation would be easier and cheaper. Only the other day I visited a lone farmhouse which a friend wished to take for the summer, and I found that the proprietor, having taken the soil-pipe of a recently erected watercloset into a cesspool alongside a deep well sunk in the chalk, had rendered his house unlettable to any thinking person; and, lastly, I recently heard of a friend who took a moor in Scotland and wished to have rational methods of sanitation, but the noble owner, bitten by the modern craze for water, would allow nothing but water carriage, and accordingly laid his filthy pipes to foul the babbling highland burn, and deprive the soil of that of which it was in need.

Again, in institutions such as workhouses, barracks, schools, and the like, water carriage is often adopted, notwithstanding the favourable conditions for rational methods. The ignorance of soldiers in this matter is an acknowledged cause of the sickness and mortality during campaigns. There seems, in short, a very great necessity for directing attention to the "shortcomings" of water-carried sewage.

What do you propose? will be the next question. My answer is fair play and no compulsion. Much as I believe in the good of spreading sanitary knowledge, I have little faith in the efficacy, and a potent belief in the dangers, of sanitary legislation, whereby blunders are stereotyped.

The first thing necessary is an equitable adjustment of sanitary rates. Borrowing for the purpose of constructing sewers should be disallowed, and those who do not need the sewers should not be called upon to contribute towards them—at least, not to the same extent as others. The present inequitable adjustment of sewer rates is a premium on jerry-built houses without curtilage. Encourage the man who has a little bit of garden to make use of it. Enforce the Pollution of Rivers Act against individuals, even against proprietors of highland moors. Let us have a real inspection of nuisances and a harassing of evil doers, and let us discourage by every means in our power the building of houses side by side, and almost back to back, with no outlet but a hole. Let water be paid for by meter.

I have every sympathy with the agitation for getting allotments for the poorer classes. The best and most economical allotment is one close to the house where refuse may be buried and in due time bring forth. Those who advocate "sewage farming" tell us that an acre is necessary for every 100 inhabitants. How infinitely better if the 100 people could absolutely live on the acre of ground in (let me say) twenty cottages, each cottage having one-twentieth of an acre. How infinitely better for the man to till this little plot in his spare time than to occupy his leisure by braying politics in a public-house.

Let us calculate the produce of this plot of ground in terms of potato. An acre of a field will produce an average crop of 7 tons; the twentieth of an acre would produce 7 cwt., or 784 lb. As these would be for home consumption, and would save the man from disbursing money at a retail shop, we may take the value at the average retail price of 1*d.* per lb., or £3 5*s.* 4*d.*, or for the sake of simplicity say £3. To give one-twentieth of an acre to every five inhabitants would make a town inconveniently big, it may be said. I think not; 100 to an acre is 64,000 to a square mile, or making a very liberal reduction for space occupied by roads, let us say 50,000 to a square mile. This does not sound like an inconvenient scattering of houses. The inhabitants would make £30,000 a year by the produce of the land, a gain of which Free Trade could not deprive them; and there would be no sewer rate, no plumbers' bills, and certainly a vast increase of health, happiness, and contentment.

What I am advocating is no utopian scheme, and I am not talking without some practical experience. A few years ago I bought twenty cottages adjoining a garden which I have in the country. Many of them had been built with a very insufficient curtilage, and their old-fashioned sanitary arrangements made the garden anything but pleasant. My first step in improving these cottages was to do away with the old-fashioned pits, which were not suited to the spot and were always full of water, and replace them by pails. The cottages are systematically scavenged every day, and all refuse, inclusive of food refuse, excrements, and ashes, are buried immediately in the garden. There has been a complete cessation of all offence, and my garden holds the proud position of being certainly one of the most fertile in the district. Roses and other flowers, and all the ordinary garden fruits and vegetables, flourish therein in great luxuriance. The æsthetic aspects of the place have been increased, and in no way diminished, by the course I have pursued. I wish it to be understood that I am no mere theorist, but that I practise what I preach.

I have dealt with this subject from rather a different point of view in a little book, "Our Duty in regard to Health," which I wrote for the Council of the Health Exhibition. Those who may care to pursue this subject further may get the book of Clowes and Co., the publishers, at Charing-cross.

ON A CASE OF

SUCCESSFUL SUTURE OF THE BLADDER, THROUGH AN ABDOMINAL INCISION AFTER TRAUMATIC RUPTURE.

BY T. HOLMES,
SURGEON TO ST. GEORGE'S HOSPITAL.

THE operation of sewing up a rent in the bladder is still so novel, and has been so seldom successful, that I think the following case will be of interest in connexion with the two recently published by Sir W. MacCormac in THE LANCET.

Henry P——, aged twenty-four, was admitted into St. George's Hospital in the night of June 9th, 1887. He had been drinking for several days, and on the day of admission, about 7.30 P.M., in a quarrel, he received a kick in the abdomen. He had not emptied his bladder for an hour before the injury, and had been drinking freely in the interval. He felt great pain on the receipt of the kick, walked home (about a quarter of a mile), and then, as the pain did not abate, and he could not void urine, he was taken, at 9 P.M., to Dr. Powell of Battersea-park-road, who passed a gum catheter, and drew off about five ounces of blood-stained fluid; but, suspecting rupture of the bladder, sent him to the hospital. Mr. Vernon (then house surgeon) passed a silver catheter about 11.30 P.M., but drew off only about one ounce and a half of bloody fluid. I saw him about 1.30 A.M.—i.e., about six hours after the receipt of the blow. He was in great pain, but not collapsed. Examination of the abdomen showed nothing abnormal, but as the symptoms appeared to point to ruptured bladder, I decided, in consultation with Mr. Bennett, to whom I was indebted for most valuable assistance, to examine the patient under ether, with a silver catheter, with a view to abdominal section and suture, if that operation should seem called for. When first passed into the bladder the instrument drew off hardly anything, but on pressing it onwards a large quantity (more than half a pint) of blood-stained fluid was obtained, and the point of the catheter was felt nearer the umbilicus than the pubes. Judging that the catheter must be outside the bladder, the pubes being shaved and the skin washed with carbolic lotion, I made an incision in the middle line for about three inches and a half above the pubes, and deepened it gradually till the peritoneum was exposed, covering some coils of small intestine. The catheter was felt through this. The urachus was easily distinguished passing up to the umbilicus, but the position of the bladder could scarcely be defined. It seemed therefore certain that the rent was not extra-peritoneal. Accordingly the peritoneum was opened pretty freely, the intestines pushed upwards with a flat sponge, and the rent in the bladder exposed. This was of a horseshoe shape, convex towards the right side. The finger introduced into it felt the catheter, and when the point of the instrument was withdrawn the opening of the urethra into the bladder could easily be distinguished. The rent was judged to be about two inches in length, and was completely in sight. A suture was introduced behind its posterior termination, to hold and pull forward the bladder, and then the rent was closed by means of eight points of suture of fine silk, soaked in carbolic lotion,

Digitized by Google

passed through the peritoneal coat and muscular tissue, but avoiding the mucous membrane. The sutures were carefully examined after they had been tied, and if the interval appeared to gape at all a fresh one was introduced, but the bladder was not injected. After the eight permanent sutures had been tied the first or temporary suture was withdrawn. The peritoneal cavity was washed out plentifully with warm water. No clots were seen in it and but little bloody fluid. Then the abdominal wound was closed by four deep silver sutures, in which the peritoneum was carefully included, and four superficial ones. Finally, an incision was made in the median line of the perineum, which seemed to open the urethra, and an attempt was made (unsuccessfully as it turned out) to pass a drainage tube that way into the bladder. No spray was employed. The operation lasted about an hour. A morphia injection was administered, and the patient slept well, but vomited after the ether. Next morning the pulse was regular and strong; temperature 101°. He complained of thirst and of pain in the lower part of the abdomen, but had voided urine on three occasions naturally; it was blood-stained and contained a good deal of albumen. The drainage tube was removed as useless, and the perineal wound allowed to close.

Daily notes are unnecessary, for there were no symptoms to record. I looked at the wound on the fifth day, and found it nearly healed. The temperature fell gradually to the normal, and the pulse came down on the fifth day to 76. The bowels remained constipated for a week, and were then acted on painlessly by castor oil. On June 22nd (the thirteenth day after the accident) all the sutures were removed from the abdominal wound. As there seemed a little irritation about the lower part of the wound, a few pieces of strapping were applied. He wanted to get up, but was persuaded to keep quiet for a few days more. On June 29th he was allowed to leave his bed, as he appeared perfectly well. The wound seemed completely healed. The temperature had been exactly normal for more than a fortnight. He left the hospital shortly afterwards, and was seen the other day in perfect health.

Remarks.—It was long considered doubtful whether a rupture of the bladder into the peritoneal cavity had ever occurred without a fatal result, though Chaldecott's[1] well-known case was usually accepted as proving the possibility of survival. In that case, however (admitting the correctness of the diagnosis), it appeared evident that the patient owed his recovery to the fortunate accident of the limitation of the extravasation by adhesions, rapidly formed in the peritoneal cavity in the course of the peritonitis, which speedily followed the injury. Now, it is equally evident that peritonitis does not necessarily ensue at once;[2] it is, in fact, I believe, rarely developed even as early as a day after the injury, and up to that time, and very probably long afterwards, the injury is susceptible of successful treatment.[3]

Now the question occurs what this treatment ought to be? It seems to me undeniable that cases of traumatic rupture, both intra- and extra-peritoneal, have recovered under various kinds of treatment and under no treatment at all. But they are very few indeed, so few that, as I have remarked above, many surgeons, a very short time since, denied the possibility of recovery from the intra-peritoneal injury. Writing as late as 1875, in the first edition of my work on the "Principles and Practice of Surgery," it was not without hesitation that I ventured[4] to argue that the free admission of healthy urine to the peritoneal cavity, through a rupture of the bladder, need not be followed at once by peritonitis, and also to propose what I have long believed to be the best treatment—viz., to sew up the rent by abdominal section.[5] Singularly enough, from that time till the occurrence of the present case, I have never had an opportunity of putting my own suggestion into practice; but in the following year Mr. Willett[6] performed the operation without having heard of my suggestion, and it was repeated in 1878 by Mr. C. Heath.[7] Both these attempts proved unsuccessful. In Mr. Willett's case the rent was imperfectly closed, and the operation was undertaken too long after the accident to have a very good chance of success. In Mr. Heath's case the suture (a continuous catgut one) seems to have been perfect at first, but to have given way on the third day after the operation, possibly from the softening of the catgut. These two failures were so far discouraging that Mr. Heath says he "cannot recommend the proceeding for adoption when there would be the best chance of success—viz, immediately after the accident"—and expresses his preference for catheterism of the bladder and peritoneum and washing out the peritoneum through the catheter, as practised by Dr. H. Thorp, in a case reported in the *Dublin Quarterly Journal* for Nov. 1868, which Mr. Heath accepts as one of intra-peritoneal rupture, though the diagnosis appears to me to be not quite certain. Thus the matter stood until Sir W. MacCormac's two cases, which were published in the latter part of last year,[8] though one of them occurred in the previous year. Both these cases were completely successful, and by "completely" I mean that the patients not only recovered, but recovered without any symptom of peritonitis. In Chaldecott's and Thorp's cases peritonitis occurred. The other cases of recovery referred to by Mr. Heath—viz, Walker's and Mason's, the former certainly and the latter probably—were extra-peritoneal, and in Mason's case there was peritonitis.

In the table appended to Sir W. MacCormac's oration on Abdominal Section for the Treatment of Intra-peritoneal Injuries,[9] a table of sixteen cases is given in which the abdomen was opened in order to expose an intra-peritoneal rupture of the bladder. Of these, however, two (Nos. 9 and 10) should be excluded, for in one it is distinctly stated that there was no intra-peritoneal injury, and in the other there is no proof that there was. Of the fourteen remaining, in four cases the rent in the bladder was not sewn up (Nos. 2, 5, 11, and 15), and these, therefore, were treated by an operation totally different in principle from the remaining ten, in which an attempt, more or less successful, was made to close the whole rent. Of these ten patients, only three survived—viz., Sir W. MacCormac's own two cases and one by Mr. Walsham, which is as yet unpublished. Adding my case to the above, we should have eleven cases of suture of the bladder with four recoveries—a most gratifying proportion of successes in an injury which is otherwise almost uniformly fatal, but a proportion which, I have no doubt, will be rapidly increased as the diagnosis becomes more known and the details of the treatment better understood.

In the limits of this paper I cannot adequately discuss the question of diagnosis; yet it has so vital a bearing on the treatment that I must not pass it over entirely. In by far the greater number of cases which I have seen, the diagnosis has been plain from the beginning, but there are a few in which the patient can pass some urine, or in which, as in Sir W. MacCormac's second case, he feels no wish to do so, and the symptoms of the injury are masked by those of the contusion or possibly fracture of the parts around. It is in these cases that a careful examination under anæsthesia is so important. In the case before us, the catheter readily drew off more than half a pint of urine (or urinous fluid) mixed with blood, and for a moment the diagnosis seemed at fault. But when we reflected that the bladder had been thus evacuated twice previously—viz., first by Dr. Powell and next by Mr. Vernon, the house surgeon, and that after the withdrawal of the fluid the point of the catheter could be felt more than half way up to the umbilicus, it appeared impossible that the bladder wall could reach up to so high a point; so that we felt sure the point of the catheter was in the peritoneal cavity, as proved to be the case. Now this, I would urge, not only justified, but absolutely indicated the performance of an exploratory operation. I am aware that, in some cases of the kind, the bladder has been found unruptured and greatly distended, but the previous catheterisations rendered this very improbable in this case, while the great pain the man had felt immediately on, and ever since, the injury, and his inability to pass urine, rendered the

[1] Prov. Med. and Surg. Journ., 1846, p. 333.

[2] See the case quoted in my work, referred to below, where a man walked to the hospital on Monday morning, displaying no distress of any sort except from inability to pass urine, though the bladder had been freely ruptured into the peritoneal cavity on the Saturday evening. So in Sir W. Mac Cormac's second case, twenty-six hours had elapsed and there was no peritonitis.

[3] Sir W. Mac Cormac (THE LANCET, vol. ii., 1886, p. 1118) quotes a passage from Sir H. Thompson's article in the third edition of the System of Surgery, as showing that Sir Henry believes that traumatic rupture is uniformly fatal. A more careful perusal of the passage would have shown him that Sir Henry is here speaking only of spontaneous rupture in cases of retention.

[4] Op. cit., p. 216.

[5] Sir W. Mac Cormac says that the same operation has been advocated by Lurrey, Legouest, Gross, and Cusack. He gives no references, but it may be so. At any rate, I never heard of the proposals of these authors, and they seem to have attracted no notice, for they are not referred to in any of the text-books of the period, as far as I know.

diagnosis still more probable. Next comes the question, in cases where an exploratory operation is decided on, whether it should be done through the perineum or the abdominal wall. My own opinion is very decidedly in favour of the latter course. I think, for reasons I will give presently, that a perineal incision is useless, and therefore hurtful, in cases where the injury is intra-peritoneal, and sutures are introduced through an abdominal wound. If the perineal incision is used, it ought, I think, to be as an alternative, not as an accompaniment of abdominal section and suture, and I hope to show that it is a very inferior alternative. An exploratory incision above the pubes gives much more easy and complete access to the whole front, fundus, and sides of the bladder, it has the great recommendation that the injured part is exposed to sight as well as touch, and the surgeon has the choice of opening the peritoneum or not, as he finds necessary.

Having decided to perform abdominal section the surgeon ought, I think, to lose no time. This is not quite such a platitude as it seems at first, for a good light is very necessary, and it crossed my mind whether a delay of a few hours might not be advisable in order to wait for daylight. But I think the event showed that we judged accurately in proceeding at once. When all operating theatres are provided with the electric light, or perhaps some even more perfect means of turning night into day, the question will not occur, at least in hospitals. When the rent is exposed, it must be traced to its deepest—i.e., posterior—termination, and it seems to me that the main (if not the only) difficulty in the operation is here. Luckily, in this case, it was quite easy to bring the whole rent into view. Sir W. MacCormac found that the transverse division of the parietal peritoneum was effectual in both his cases. When the posterior end of the rent is defined the sutures must be applied quite close to each other, but the continuous suture ought, I think, to be discarded. Silk, well carbolised and thin, seems to me indisputably the best material. Ought the bladder to be distended on the completion of the suture in order to make sure that it is water-tight? This is recommended by Mr. Willett,[10] and was practised by Sir W. Mac Cormac and other operators, and therefore it is presumptuous in me to argue against it. I do not know whether it was used in Mr. Walsham's successful case. My patient did very well without it, and I think that when the surgeon has the whole rent clearly in view it is superfluous. I am clearly and decidedly against any abdominal drainage if the rent is sewn up and the peritoneal cavity is free from inflammation, and has been well washed out. Nor, after the experience of the present case, do I think that the operation ought to be complicated by perineal cystotomy. In Mr. Teale's case (No. 13 in Sir W. Mac Cormac's table) the patient's death seems to have been caused by this wound, while all was going on well about the rent in the bladder. In my own case, it was merely a useless complication. But if the surgeon decides on doing it, he should make the perineal opening before sewing up the rent. After closing the abdominal incision I found it quite impracticable to open the collapsed bladder without a staff, which I judged it imprudent to introduce. Nor do I know that it is wise to use the catheter in the after treatment. It was not used in the above case, nor in Sir W. MacCormac's second case at all, nor in Mr. Walsham's after the first day; and if the rent is well sewn up it is, I believe, safer to trust to the patient's own powers. At any rate, if a catheter is used it should be of the softest material and not left in, but passed every few hours during the first day only. Paring the edges of the cleft, which Mr. Rivington[11] speaks of, should, in my opinion, be entirely reprobated.

The sum of all this is that in this, as in all other peritoneal operations, our aim should be to avoid all unnecessary complications, and trust to the perfect apposition of the wound in the bladder, and the thorough cleansing of the peritoneal cavity to ensure success. And I believe that with such treatment, the majority of cases will survive, if operated on early.

There other methods of treatment have been practised with some success, and ought to be mentioned, though I have no space for their adequate discussion. I mean the treatment by drainage, either through an abdominal wound (as in the cases above referred to, Nos. 2, 5, 11, [illegible] in Sir W. Mac Cormac's table) or through a perineal wound, or through a catheter, as in Dr. Thorp's case. The grand objection to all these plans is the extreme risk of peritonitis. It seems to me quite impossible effectually to guard against the entrance of irritating fluid and the products of inflammation into the peritoneal cavity, except by sewing up the wound. If this be left unstitched, it can only close by a gradual process of inflammation and granulation—a process which in the perineal operation, and in the method adopted by Dr. Thorp, is being continually interrupted by catheterising and syringing the peritoneal cavity through the lacerated wall of the bladder. I would therefore entirely reject the perineal operation and Dr. Thorp's method; while, as for the abdominal operation without sutures, I should reserve it for the cases in which it is found impossible to sew up the whole rent, and for those in which peritonitis has already begun and the edges of the rent in the bladder appear unhealthy. But I repeat that, as surgeons acquire greater confidence in the operation by suture, and perform it constantly in the cases where, as Mr. Heath truly says, there is "the best chance of success—viz., immediately after the accident," we shall not often meet with the latter class of cases; while, as to the impossibility of commanding the whole rent, we may hope that the plan adopted by Sir W. MacCormac of dividing the parietal peritoneum will prove successful in the great majority of difficult cases. Certainly, to judge by the description, both of his cases were of more than ordinary difficulty.

On the whole, I submit that we have now sufficient evidence to show that suture of the bladder through an abdominal incision is the best method of treating these grave injuries—the method which should first occur to the surgeon, and which should not be given up until exploration has proved it to be impracticable, when the method by drainage through the abdominal incision should be adopted.

ON RELIEVING TYMPANITES BY PUNCTURE OF THE ABDOMEN.

BY JOHN W. OGLE, M.D. OXON., F.R.C.P.,
CONSULTING PHYSICIAN TO ST. GEORGE'S HOSPITAL.

(*Concluded from page 106.*)

HAVING gathered information respecting the utility of puncture of the abdomen for dangerous tympanites from books, old and new, which record the results of individual experience, I will occupy a little space by an exposition of the teaching on this subject to be gathered from a few of our systematic works and text-books.

For this purpose I will commence by noticing the observations of the late Sir Thomas Watson (πολλῶν αντάξιος ἄλλων), whose opinion may well have greater weight than a dozen others. In his lectures on the Principles and Practice of Physic,[1] writing of mechanical occlusion of the intestinal tube, he quotes the rough-and-ready custom which obtains amongst farmers of piercing the distended abdomen of cattle, when they are, as it is said, "blown" by over-feeding on wet clover, with a hay-fork, and says that if he himself were "the subject of such pressing and prolonged torment [caused by distended intestine], I should try to have the inflated bowels eased by puncture with a fine trocar.[2]

Romberg, in his "Manual of the Nervous Diseases of Man,"[3] in one section treating of intestinal paralysis[4] from arrested action of sympathetic centres, speaks of cessation of peristaltic movement; the intestine, possessing no power of resistance, becomes distended with liquid and gaseous fluids. He states that "tympanites puerperalis sometimes threatens danger, even without antecedent affections of

[1] Vol. ii., 5th ed., p. 548.

[2] This strong recommendation of the operation is much in contrast with what Watson says, with his usual wise caution, of the operation of opening the colon, and establishing an artificial anus. Of this procedure, he observes that in an appropriate case he should think it his duty to mention, but he should be slow to recommend, this "anceps remedium."

[3] Syd. Soc. Ed., vol. ii., p. 347.

[4] Romberg observes that "intestinal paralysis occurs secondarily to other diseases, first of the intestinal canal itself; as in enteritis, in the most marked form in gangrene of the intestines, in peritonitis intestinalis and dysentery, in blood diseases, typhus, phlebitis, and inflammatory or septic puerperal states."

Digitized by Google

the bowel." He remarks that the stomach may be so much distended as to fill the abdomen.

Dr. Flint, in his treatise on the "Principles and Practice of Medicine" (1868)[5] alludes to "the formation of gas resulting from over-repletion of the stomach to such an extent as to cause sudden death. Two instances of this kind have fallen under my observation."[6]

In Dr. Bristowe's "Theory and Practice of Medicine" (p. 696), this operation of puncturing the abdomen is alluded to as being one of little or no danger; it is stated that distension may be relieved by puncturing the distended gut with a grooved needle or fine trocar and cannula. And in Quain's "Dictionary of Medicine," Dr. F. Roberts observes that "in extreme cases it is allowable to puncture the large bowel in several points by means of a very small trocar, and thus afford an exit for the contained gas."

In J. G. Smith's "Abdominal Surgery" (p. 79), it is stated that, in tympanites associated with abdominal operations, tapping with a fine trocar may give temporary relief; but this is so slight and so evanescent as to be practically of no account.

Mr. Erichsen, in his "Science and Art of Surgery,"[7] speaking of the operations in question, observes that by means of the trocar or aspirator, it "has been frequently performed, sometimes with great relief to the patient"; but he gives cautions against moving the cannula about needlessly in the gut. He remarks that the puncture is rarely followed by any escape of gas into the cavity of the abdomen. In some apparently helpless cases, he says, relief of the obstruction has been known to follow the paracentesis of the intestine.[8]

The above citations constitute all the written experience which seemed to me desirable to select and collate for the purpose of enabling the reader to judge of the value of the operation in question; and perhaps already the same reader may be reminded of the adage, "L'auteur se tue à allonger ce que le lecteur se tue à abréger." But I cannot close this communication without presenting also the results of a few inquiries which I have made of friends and colleagues as to their individual and personal knowledge of the use of puncture in tympanites.

Mr. Hussey of Oxford tells me that he has punctured the intestine during the operation for strangulated hernia, and that, when he was a pupil, his master suggested puncture of the stomach in cases of excessive tympanites.

Sir James Paget has recently told me of a patient between sixty and seventy years of age, very feeble in body and mind, whose abdomen became distended to the utmost, after many days of complete obstruction or inaction of the bowels. "She appeared to be dying," he observes, "and I had no hope of doing more than relieve her distress by puncturing the intestines at the tensest places. I did this with a small trocar and cannula near each ilium, and at the upper part of the abdomen. Air escaped in large quantities, and the abdominal wall sank down. Some weeks afterwards I heard that the patient was in comfort, and that her bowels were acting."

Mr. Teale of Leeds, to whose use of the operation I have before referred, tells me that he has had no recent experience of puncture of the abdomen for flatulent distension. He says that he believes the operation to be "most effective when the large intestine is the seat of puncture. A puncture of small intestine only relieves a few inches, and is not entirely free from danger, as I have heard of fœcal leakage into the peritoneal cavity from such a puncture. It is most likely to be useful, and will be most free from risk in functional tympanites, especially of the large bowel, and to be of least use, and most dangerous, in obstruction of the bowels when the intestines are full of churned-up yeast-like gas and liquid."

Sir Wm. Jenner informs me that he has had the intestine punctured in several cases of extensive tympanites, and that in no case has any evil result followed. In one case, in which there was malignant disease of the sigmoid flexure of the colon, with obstruction, "two interesting facts followed the operation—one was that the gas which escaped through the tube caught fire, and the other that the removal of the flatus was followed by action of the bowels, as though the great distension of the gut had interfered with its full action." In another case of cancer in which Sir W. Jenner had sanctioned puncture of the bowels, each puncture of the bowel was found, after death, to be surrounded "by recent formation of cancer nodule, as if the irritation of the puncture had caused afflux of blood, and in place of ordinary lymph cancer had been formed."

Sir George Paget of Cambridge tells me that he has had only one case of tympanites requiring the puncture. The operation gave relief, but the patient died. Dr. Church and Dr. West, of St. Bartholomew's Hospital, and my colleagues, Dr. Dickinson, Dr. Whipham, and Mr. Holmes, inform me that they have resorted to the operation. Dr. Harper performed the operation in 1875, when house surgeon at St. George's. Mr. Dent tells me that he has a strong disbelief in the utility of puncturing in tympanites. Dr. Montague H. Jones, of St. Mary's Hospital, has practised it, though not with much advantage, in two cases of typhoid fever and one of intestinal obstruction.

Dr. Oliver of Newcastle-on-Tyne has given me the details of four cases, in which he had the operation done for tympanites with, excepting one case, the greatest relief. All but one were cases of mechanical obstruction. Dr. Oliver regards the operation "as not in the least dangerous, and as one almost certain to give 'relief.'" In one case he tested the gas which escaped by the puncture, but did not find it inflammable.

Dr. Gray, who has had large experience at the Radcliffe Infirmary at Oxford, tells me that his only knowledge of puncture for tympanites is derived from a single case. The patient was a lad of fourteen or fifteen years of age, suffering from severe typhoid fever. He observes: "One morning I found him to all appearance on the point of death from asphyxia, the upper half of his belly being so enormously distended that the diaphragm and lower thorax were fixed and motionless. I directed the house-surgeon immediately to thrust a small trocar into the most prominent part of the swelling (believed to be the stomach); and this done, the gas slowly blew off, the tympanites quite subsided, and the patient's relief was complete. He died, however, about three days afterwards of uncontrollable diarrhœa." After death ulceration of the ileum was found, but no peritonitis. The only trace of the puncture-wound (and that rather a doubtful one) was a little pink spot on the peritoneal surface of the stomach; no mark on the inner mucous surface of the stomach corresponding to the faint one on the peritoneal surface could be detected. Dr. Gray proceeds to observe that "the harmlessness of the puncture made much impression upon me. The cause of this probably was: 1. Thinning of the structures from extreme dilatation. 2. The small size of the trocar. 3. The urgency of symptoms requiring bold and rapid thrust-in of the trocar."

Sir Joseph Lister tells me that his experience of the operation is confined to one case. This was not favourable for the trial, but still death would have occurred earlier had the operation not been done. He does not regard the operation as absolutely free from risk, as "the valving of the puncture, which occurs when the distended bowel collapses, may be undone by subsequent extreme distension." Dr. Morgan and Dr. Dreschfeld, of Manchester, have sent me several cases illustrating the benefits obtained by the operation. Sir W. Mac Cormac considers the operation dangerous because of the risk of subsequent escape of fæcal matter, which would set up septic peritonitis. My friend Dr. Fox, of Clifton, has been in the habit of advising the operation, and states that he has never found anything but relief from it.

Dr. Henry Lewis of Folkestone, formerly house-surgeon at St. George's Hospital, has sent me the particulars of the following highly interesting case. He had under his charge a young lady about fifteen years of age, with "peri-typhlitis." "The abdomen became enormously distended, and death was imminent apparently, chiefly in consequence of the respiration being embarrassed by pressure upon the diaphragm, from the extreme distension. After a consultation with my brother," he says, "it was decided to relieve present distress by the use of Hemley's exploring aspirator. This

[8] Dr. A. T. Myers has been so good as to give me the following references to the subject, which I have not had time to look up:—Brogniez: Nouveau Procédé d'Entérotomie ou le Ponction Intestinals (Bull. Acad. Roy. de Méd. de Belge; Brux., 1842-43. ii., 151—158). Augnet: Ponctions capillaires de l'Intestin (Bull. Méd. du Nord; Lille, 1875, xiv., 125—130). Evrard: Ponction Intestinale dans les cas de Météorisme (Trans. de Méd. et Chir. Prat.; Paris, xlvii., 158). Fronmüller, G., jen.: Ponction der Gedärme (Memorabilien; Heilbr., 1876, xxi., 208—210). Laub: Tilfaelde af Ileus helbredet ved Punktur af Tarmen og Klysopumpe (Hosp. Tad, Kypbenh., 1869, xii., 157, and 1870, xiii., 41). E. W. Lee: A case of Puncture of the Intestines for the Relief of Over-distension with Gas (Chicago Med. Jour., and Exam., 1877, xxxv., 381—83). A. Tomes: Tapping the Bowel (Indian Med. Gaz.; Calcutta, 1882, xvii., 211). Others might no doubt be found, if the prolific literature of the day were ransacked.

Digitized by Google

was done freely in several places, and enormous quantities of fœtid gas escaped into the room. This was, in subsequent operations, deodorised by passing it through a solution of carbolic acid. The following day the abdomen was again distended, and life was again in immediate danger. The abdomen was again freely punctured, with the same instant relief. For two or three times more the same series of phenomena occurred, after which the patient very slowly but surely recovered. The punctures were made into the most prominent portions, freely and deeply, quite irrespective of any possible consequences." Dr. Lewis thinks that the mitigation afforded to the system by the evacuation of so much poisonous gas is as important as the mechanical relief obtained.

As the position sought to be maintained in this communication would not be complete without illustrations derived from the *pathology of the lower animals*, I will close it by a few quotations from writers and practitioners in veterinary medicine.

The earliest direct mention of injury to cattle from tympanites which I have come across is in the writings of Pamponius Mela, who travelled in Ireland about A.D. 40, and who describes the climate, soil, and people of that unhappy country. He says that the cattle are wont to burst from eating green food too much. He writes as follows:—"Terra autem adeo fecunda herbis, non lætis modo, sed etiam dulcibus, ut se exiguâ parte diei pecora impleant; et, nisi pabulo prohibeantur, diutius pasta dissiliant." This notice I quote from a polemical letter signed "Viator," in *The Times* of June 24th, 1887.

Sennertus, in his work "Epitome Institutionum Medicinæ," Lib. II., Part II., cap. vii. (Lugduni), 1644, when treating "De Humoribus, &c.," says that he was conversant with it, and with its treatment. After giving the causes of flatulence in cattle, and the treatment of evils arising from it, he observes: "Rusticæ mulieres ut periculum ex flatibus et ventris inflatione præcaveant, ventrem arctis fasciis constringere; et abdomen fubulis perforare solent."[9] The above passage has been alluded to by one or two later writers, when speaking of tympanites in man.

No doubt, if one could hunt up authorities, many accounts could be found of this practice. The next record of it, of which I have note, is in a work entitled "Mémoires Littéraires et Critiques pour servir à l'Histoire de la Médecine," 1775, as quoted by M. Barrière, who communicated a paper in 1783 to the *Journal de Méd. Chir. et Pharm.* upon "Meteorismus" from indigestion, in the case of the horse, relieved by puncture. The paper was based upon the operation which he had successfully performed, after all routine means had failed. In this paper he particularly points out that the right moment for election of the operation must be judged of by the state of the pulse; as, if it is found to be more than twice as frequent as it is in health, death is near. In some remarks on this paper M. Husard alludes to the practice of cutting boldly into the stomach of cattle when over-distended and with the hand taking the food out of the stomach.[10] He says that one cow does not die in twenty so treated. He mentions the names of Vitet, Paulet, Vicq d'Azyr, Bourgelat, and Chabert in connexion with the operation, and speaks of the gas liberated *as being inflammable*. Modern works on veterinary surgery make reference to the procedure in question, the majority, I think, approving. Thus, in a work entitled "The Horse in the Stable and the Field," by J. H. Walsh, p. 506, it is stated that "sometimes the distension of flatulent colic goes on increasing, and the only chance of recovery consists in a puncture of the cæcum, as it lies in the right flank, where, according to French veterinary writers, it may often be opened when greatly distended without dividing the serous covering." In the posthumous extracts from the veterinary records of the late John Field, I find notes of the case of a horse (p. 147) where death was attributed to the enormous swelling of the abdomen and to other symptoms caused by paralysis of the intestines. At page 83 a case of tympanites in the horse is related in connexion with inflammation of the bowels, in which, owing to excessive dilatation, the flank was punctured with a trocar. This was, however, without relief. Mr. Hussey of Oxford tells me that, forty years ago, he was told by the wife of a Scotch farmer that distension of the abdomen in cattle was very common, when the cattle first went out to grass, and that they were often, for this, "stabbed" in the loin below the last rib, but that if the puncture was done "on the wrong side," it was likely to be fatal. Dr. Aquilla Smith of Dublin informs me that in Ireland "our doctors practise puncture in cases of flatulent distension, and fasten a quill in the opening to give free exit to the flatus." He states that "some years ago a buffalo in our Zoological Gardens was operated on by a cow doctor, and had a quill secured in the opening. The animal lived for some days, and in the meantime I delivered her of a shoulder presentation, which was a difficult task." Professor Robertson, Principal of the Veterinary College in Camden-town, informs me that puncturing the rumen of cattle and the colon or cæcum of the horse, in cases of serious tympany, is an operation regularly resorted to by veterinary surgeons, and that the results are generally satisfactory. It is unattended with dangerous sequelæ. Emphysema or small "cellular abscesses" are occasionally observed to follow, but they are rarely very troublesome.

Lastly, I will quote from a remarkably interesting French work on veterinary subjects, the Dictionnaire de Médecine de Chirurgie et d'Hygiène Vétérinaires,[11] in which (tome i., p. 462), under the article "Coliques," the following statement appears:—"Si la tympanite devient trop forte, si elle gêne trop la respiration de l'animal, et le menace d'asphyxie, il ne faut pas hésiter à pratiquer l'entérotomie que l'on fait sur le flanc droit." The author speaks of the operation as having been recommended, in 1780, by Barrière and Herouard, and as having been successfully adopted by a number of others whom he names.[12] He warns against delay in having recourse to it. He states that he has, in some desperate cases, though without any real benefit, injected remedies, by the cannula of the trocar, into the punctured bowel.[13]

Such are the references to standard authorities and the illustrative cases supplied to me by living practical physicians and surgeons, which will, I think, suffice indisputably to show the great good which may be accomplished by the expedient, when timely resorted to, of puncturing the abdomen in excessive tympanites. They will be enough to demonstrate to those who have doubts or fears as to the wisdom of the procedure—that the operation is not, as some with whom I have conferred upon the matter would fain think, one to be regarded with ostrich-like indifference, to be "damned with faint praise," or, as others suppose, a wanton and necessarily dangerous, and therefore culpable, act—a species, in fact, of professional assassination; but that it is, incontestably, a legitimate and justifiable step, one that may be undertaken *tutò, celeriter et jucunde:* at any rate, that it has strong evidence in its favour as a *dernier ressort*. Their consideration will prove clearly that there are many cases in which the inexorable torments of death even can be forthwith averted by the operation in question, and Thanatos, with inverted torch, be made to give way to his brother Somnus with his poppies, medical aid stepping in, as, at once, *vitæ artifex, mortis fugator*.[14] But, in addition to immediate solace, it has been shown that *permanent good* may arise from the operation, from the fact that removal of the pent-up gas, in many cases, enables the paralysed intestinal walls to contract upon, and therefore evacuate, their contents, even after that constipation has lasted many days; and it is interesting to find that this not

[9] Sennertus quotes Dioscorides as describing a special kind of grass which causes cattle to burst, almost, and eventually to die.

[10] I am told that this mode of giving relief is now done in England, by some.

[11] The work is beautifully "got up," and well and copiously illustrated. An English translation would be a very valuable addition to our libraries.

[12] He alludes to a work by Charlier, entitled "De la Ponction dans les Coliques," Paris, 1863.

[13] This mode of dealing with cattle is ingeniously taken advantage of by the author of a well-known modern novel, "Far from the Madding Crowd," where the operation is graphically described. A number of sheep (see Chapter 21a) are represented as breaking into a field of young clover, and "getting blasted." An attendant exclaims, "They will all die as dead as nit." After a time many fell down helpless and livid, "swoln with wind," foaming at the mouth, and with quick and short breathing. "One of the ewes contracted its muscles terribly, extended itself, and jumped high into the air, then fell heavily and lay still," and died. Some recovered without operations, but forty-nine operations were performed with complete success with "a small tube or trocar, with a lance passing down the inside." "Passing his hand over the sheep's left flank, and selecting the proper point [the operator], punctured the skin and rumen with the lance as it stood in the tube, then he suddenly withdrew the lance, retaining the tube in its place. A current of air rushed out, forcible enough to have extinguished a candle held at the orifice." It would be interesting to know what authority the writer of the above has for describing the leaping into the air as a result of over-distension of the bowels.

[14] Many to whom I have spoken regarding the operation have said, "I should have liked to have done it many times, for years, but I dare not."

Digitized by Google

infrequent result was recognised by some of the oldest writers on the subject,[15] who knew that over-distension paralysed the muscular walls of the bowel. It may be suggested that in many cases of obstruction found after death to have resulted from volvulus, or twisting of the intestines (permitted in many instances by an unusually long mesentery), relief might have been obtained had the distending air been liberated by puncture. It has been shown that the danger to be anticipated from the operation is, no doubt, that of peritonitis; but this would seldom be from direct injury to the serous membrane by the instrument, but from the oozing or leakage into the peritoneal cavity of some of the contents of the bowel.[16] In some cases, however, in which at first sight after death it would appear that the puncture had caused harm by letting out fæcal matter into the peritoneal sac, it seemed, upon investigation, that this had been altogether a post-mortem phenomenon. In these days, when the surgeon, with his better educated "digitus chirurgicus" and antiseptic appliances, deals with the peritoneal surface in so very fearless a manner as compared with what was customary in earlier days, when we are bidden not to shudder on reading of "mopping out" the peritoneal cavity, "thoroughly sponging out," "making complete exploration of" the cavity, &c., we may well conjecture that this surface would not gravely resent so slight an affront as the piercing of it by a very fine trocar, or an aspirator needle. Of course, as regards the surgical aspect, properly speaking, of these cases, I am not competent to make suggestions. Surgeons will know how the procedure should be conducted in individual cases; but the general mode of operation may be gathered, I surmise, by those who have any doubt, from the directions and hints contained in many of the quotations which I have presented to the reader (see especially the words of Dr. Wathen, Dr. Saunders, and Mr. Teale). A very important lesson to be gathered from the experience of many whom I have quoted is obviously the absolute necessity of not delaying the operation too long—that is, of not waiting until irreparable mischief has been effected by prolonged pressure of structures and organs, and until the muscular walls of the bowel have been so long stretched and strained that their contractile power is irrecoverable, and are *ipso facto* paralysed.

ELECTROLYSIS IN GYNÆCOLOGY.

BY THOMAS SAVAGE, M.D., M.R.C.P., F.R.C.S.,
SURGEON TO THE BIRMINGHAM HOSPITAL FOR WOMEN.

HAVING recently had an opportunity of paying two visits to the clinique of Dr. G. Apostoli in Paris, where he practises the treatment of certain diseases of women by electrolysis, I have thought it might be useful to detail to the readers of THE LANCET some of the observations I made. There were each day between thirty and forty patients, all of whom came to be treated by electricity for some form of special ailment. Apostoli used simple faradisation to a considerable extent, simply as a means for the relief of pain—e.g., vaginismus, ovarian and uterine pains, proceeding from various causes. He appeared to regard it that the patients, being in pain, came to have it relieved, and that if the frequent application of faradisation gave the desired relief it was sufficient, leaving the disorder itself to take its own course. Some of these cases which I saw were prolapsed ovary, small cystoma (?), adherent organs, the result of chronic inflammatory mischief, hysteria, &c. The application certainly has an anodyne effect, as evidenced by the presence and absence of tenderness on pressure, &c., before and after its performance. It appeared, also, in some instances to have a soporific effect. I take it, however, that this is only the resuscitation of a method of treatment that has been long known and practised.

The *galvano-caustique chimique* is, however, the essential element in Apostoli's special work. The clinical history and treatment of a number of cases were read to me, and I was shown the plaster models of some of the abdominal tumours, and certainly the condition of the patient in every instance had considerably improved. In cases of uterine myoma, a dozen or more of which I saw and examined, the hæmorrhage had ceased, the tumour had diminished, pressure symptoms had subsided, and the patients expressed themselves as being very decidedly ameliorated. Dr. Apostoli uses the positive pole (acid), which is caustic and therefore astringent, for cauterisation to the interior of the uterus for endometritis, subinvolution, and bleeding myoma; and the clinical notes in the latter class showed that the loss had been arrested after three or four cauterisations. The applications are made at intervals of two or three days, sometimes longer, and amount to a dozen or more altogether. The electrode remains in utero about five minutes at each sitting and does not generally give rise to much pain. There appears to be an entire absence of danger in this, as also in the negative electrode.

The negative pole (alkaline and destructive), which has the effect of causing a flow of blood and destruction of tissue, was used for myoma by way of puncture into the mass of the tumour, causing diminution of size and amelioration of the pressure symptoms. The puncture was made with a steel rod, protected in the vagina by a celluloid sheath, having a naked point of about two centimetres. This is allowed to remain in the tumour for five minutes, and is repeated from time to time as considered necessary. Formerly punctures were made of 6 or 7 centimetres. The patient has an anæsthetic if thought desirable, and rests in bed afterwards for an hour or two. No bleeding of importance has been noticed as a result of the puncture; when it has occurred, it has hitherto always been arrested by putting the vaginal wall on the stretch by means of a plug or the speculum. For the positive cauterisation a platinum intra-uterine sound is usually employed.

The galvano-caustic (negative) is sometimes used in cases of old, never acute, perimetric inflammation, acting, as is supposed, as a derivative. It is never used for the arrest of hæmorrhage. Most of the cases of pelvic peritonitis that I saw were on the right side, and I was struck by the absence of badly ruptured perineum and cervix, where the symptoms were old inflammations of post-puerperal origin. I saw negative puncture applied in a case described as "subacute perimetritis," which, on examination, showed a mass of exudation and tumour round the uterus. I saw a case of mucous polypus of the cervix, which Dr. Apostoli was going to treat with the negative application. He preferred this plan to the usual one of excision or ordinary caustics, as the electrolytic application would not only burn away the polypus, but also so alter the character of the mucous membrane of the cervical canal as to prevent a recurrence. The intensity of the action is regulated by a galvanometer, which measures up to 250 milliampères. Action is usually allowed from 100 to 150—more often the latter. Platinum is considered too soft for the negative puncture, and the steel rod which is employed is either simply pointed like a packing-needle, or spear-shaped. The steel point, after use, does not appear to be at all acted upon by the alkali, nor did it show any trace of blood on its withdrawal.

With every patient the dorsal position is adopted. The hands are washed in sublimate solution before examination, and the vagina is carefully irrigated with the same. All the instruments are kept in a porcelain dish containing antiseptic fluid. The abdomen is covered with a large piece of wet clay in which the opposite conductor is embedded—negative for cauterisation; positive for puncture. This is kept, by an assistant, closely applied to the abdominal wall, and ensures safety to the skin, which is always quite cool during and after the operation. The vaginal irrigation is repeated after withdrawal of the conductor, and the canal is packed with strips of iodoform gauze, changed from day to day if necessary. One patient presented herself (a first visit) with what was considered a small ovarian cystoma; and Dr. Apostoli said that he should apply galvano-puncture (negative) to it. It appeared to me that it would be extremely difficult so to fix it as to ensure accurate puncture, and I asked the question whether it might be desirable or justifiable for the tumour to be fixed from above by the fingers, through a small abdominal incision in order to facilitate the application of the negative needle per vaginam—a sort of combined operation. I was, however, forced to the conclusion that if a small incision were once made through the abdominal wall, the easiest and surest way of curing the patient would be there and then to remove the

[15] These older writers were also acquainted with the facts, now much relied upon, that diuretics and other medicines given in cases of ascites fail to act satisfactorily until the peritoneal liquid has been discharged by paracentesis. They were also conversant with the application of electricity for the purpose of making the intestines contract in tympany.

[16] In a few cases I have heard of peritonitis having apparently surrounded the orifice made by the trocar into the outer surface of the bowel.

Digitized by Google

tumour. Dr. Apostoli is aided in his work by two admirable assistants and a most intelligent nurse.

It would obviously be impossible from an observation of two short visits to give an opinion of real value as to the merits of Dr. Apostoli's treatment. I was induced to pay my visits from a desire to learn for myself the details of applying the electrolysis, especially to cases of uterine myoma. I have long felt that we want some means other than those which we possess for the treatment of many cases of fibroid tumours of the uterus. Hysterectomy, grand and perfect when successful, has even now a larger mortality than is desirable, and can be practised only as a last resort. Will electrolysis ever be able to be a substitute for the more heroic treatment? It is our duty to answer this question if possible. With this state of mind, therefore, I am prepared to try the effects of Apostoli's method, and hope to be able to communicate in due course the results of such experience.

With my present views I thought that some of the cases I saw could have been cured by abdominal section, and on telling this to Dr. Apostoli and Dr. Woodham Webb, they both seemed to imply in their answers that when I knew more of what electrolysis could accomplish, I should be as enthusiastic in favour of it as themselves, and should substitute it for many cases now calling for abdominal section. The battery and all necessary appliances can be obtained of M. Gaiffe, 40, Rue St. André-des-Arts, Paris, at a cost including freight, &c., of about £25. I have much pleasure in testifying to the extreme courtesy of Dr. Apostoli, who allowed me to see for myself everything connected with his work, and explained most fully every detail. I had the pleasure also of meeting Dr. Woodham Webb, who most kindly assisted me by explaining what appeared difficult.

Birmingham.

BILATERAL PARALYSIS OF THE DILATOR MUSCLES OF THE GLOTTIS, WITH SUBSEQUENT PARESIS OF THE CONSTRICTORS.

BY PERCY KIDD, M.D., F.R.C.P.,
ASSISTANT PHYSICIAN AND PATHOLOGIST TO THE BROMPTON HOSPITAL.

(*Concluded from page 110.*)

THE following case, which has come under my own observation, illustrates some of the points in dispute: A. R——, aged forty-seven, a carpenter, came to the out-patient department at the Brompton Hospital on Oct. 15th, 1886, complaining of difficulty in swallowing and shortness of breath. These symptoms had appeared twelve months previously, and for some five or six months he had been losing flesh. About three months ago hoarseness developed, and the dysphagia and dyspnœa became so much worse that he was able to do very little work. For the last week he had been completely laid up owing to increasing shortness of breath. There was no history of syphilis, but he stated that he had suffered from "rheumatic gout" in the wrists and ankles. Family history unimportant. The patient was anæmic and cachectic looking, being very thin. Breath extremely offensive. Voice only slightly hoarse. Marked inspiratory stridor. Neck swollen, owing to the presence of deeply-seated groups of large hard glands in both anterior and posterior triangles, especially in the [illegible] position. Veins at root of neck distended. There was [illegible] any movement of the larynx up and down with [illegible]ration. A few shotty glands in right axilla. Left radial [illegible] smaller than right. Pupils equal. Tongue furred; bowels [illegible]pated. On physical examination of the chest the [illegible] of the left side was somewhat impaired; there was [illegible] dulness over the manubrium sterni extending a short [illegible] to the left, and over this area tracheal bre[illegible]. The breath sounds were weaker at the left apex than [illegible]. No other abnormal signs. The pharynx was [illegible] and irritable, and the larynx was in the same [illegible] cords approximated during phonation to the [illegible] but on inspiration they did not [illegible] left sixteenth of an inch. On very deep [illegible] cords almost met in the middle line, [illegible] appearance of tension of the vocal cords; indeed, they seemed to be more lax than usual. The patient was thought to be suffering from a new growth of the cervical and mediastinal glands, possibly secondary to malignant disease of the œsophagus, implicating the recurrent laryngeal nerves. The patient was admitted into the hospital under my care, through the kindness of Dr. Symes Thompson. After admission he had one or two severe attacks of dyspnœa, and preparations were made for tracheotomy, but, after a consultation with Mr. Godlee, the operation was deferred, although dyspnœa continued to be a prominent symptom. The patient was able to swallow liquids with difficulty, but not solids, and the dysphagia did not increase much for the first four or five days. The temperature varied between 98° and 100° as a rule, and did not rise above 100·5° at any time. Sphygmographic tracings seemed to confirm the idea that the left radial pulse was smaller than the right. On Oct. 21st Mr. Godlee kindly examined the patient's œsophagus, and reported as follows: "Bougie (No. 9, Mackenzie's) stops at seven inches and a half from incisor teeth. The man struggles very much, so attempts had to be short. No blood. The finger will not reach beyond the tip of the epiglottis." A few days later a marked improvement took place in the breathing, and on Oct. 26th I found that, although the dyspnœa was decidedly less, the patient's voice was now very weak and high pitched. The man could not swallow either liquids or solids, and had wasted rapidly. "Fœtor ex ore" was more marked than ever. On laryngoscopic examination the opening of the glottis was distinctly wider. When attempts were made to phonate, the cords approached one another to some extent, but in a faltering manner. This imperfect adduction could not be sustained as in singing, but after a momentary movement towards, but not quite up to, the middle line, the vocal cords diverged and took up a position midway between that of quiet inspiration and phonation. No further opening of the glottis occurred on the deepest inspiration. The impression gained was that the constrictors of the glottis acted in a weak, irregular manner, while the dilators were completely paralysed. Recourse was now had to nutrient enemata, but the patient continued to waste with great rapidity. Mr. Godlee again saw the patient, and suggested gastrostomy, more as a means of postponing the end than with any hope of long-continued relief. The chances of the operation were put before the patient, and he decided to have it done. Gastrostomy was performed by Mr. Godlee on the afternoon of Oct. 30th. The pulse failed somewhat during the operation, but improved again, and the man appeared to rally somewhat afterwards. This improvement, however, was only temporary, and he gradually sank without any rise of temperature, and died the next morning at 9 A.M. No change was noticed in the laryngoscopic appearances after the 26th, but no examination was made after the 29th. The voice preserved its weak, high-pitched character to the end.

Abstract of necropsy.—Large nodular masses of new growth were found in both anterior and posterior triangles of the neck, being most abundant towards the middle third of the neck. These masses, which were hard and white, lay mainly beneath the sterno-mastoid muscles, and were matted together, forming a nodular chain continuous with a similar growth in the posterior mediastinum. There were only a few small nodules in the anterior mediastinum, though the connective tissue here was very dense and obviously thickened. The common carotid arteries were pushed forwards and inwards by the growth, which lay to their outer side, and the left subclavian artery was somewhat compressed. On the right side the vagus was not at all pressed upon, but opposite the cricoid cartilage the nerve presented a large fusiform swelling like a ganglionic enlargement. The right recurrent laryngeal nerve was traced round the subclavian artery to its entrance into the larynx, and was not implicated. On the left side the vagus was buried in the cancerous material at the level of the upper third of the thyroid cartilage. On dissection, the nerve could be traced with ease through the growth, and, though it was somewhat flattened, it did not appear to be infiltrated. Below this point the nerve was thinner than the vagus trunk on the other side. The left recurrent nerve passed freely round the aortic arch, but was embedded in the growth along the lower part of the trachea. The superior laryngeal nerve, with its external branch, was quite free on each side. The œsophagus, from a point one inch below the cricoid cartilage down to its termination, was infiltrated and thickened. Opposite the junction of the upper and middle

Digitized by Google

third of the trachea the gullet was extensively ulcerated, and there was a ragged oval perforation of the trachea one inch and a half in length. There was a similar growth in the mucous membrane of the trachea from this point almost down to its division, with slight ulceration in places. The lower part of the pharynx contained a few miliary nodules on its mucous membrane, one just above the left border of the cricoid cartilage, but there was no infiltration of subjacent structures. The larynx was quite free from disease. The vocal cords lay in the cadaveric position, and could be moved freely to and from the middle line. There was no interference with the crico-arytenoid articulation. On removing the mucous membrane covering them the crico-arytenoidei postici looked pale and thin, but not more so than the muscles generally. The crico-arytenoidei laterales presented no abnormal appearance. The lower lobe of the left lung contained one small nodule, and there were a few enlarged glands behind the stomach and liver. The gastrostomy wound looked quite healthy, and there was no peritonitis. The rest of the abdominal cavity was free from disease. The brain with its vessels and membranes appeared quite healthy. Microscopical examination showed that the growth was a carcinoma (squamous epithelioma). In sections of the fusiform enlargement of the right vagus it was seen that almost all the nerve bundles had been destroyed, but the outlines of the bundles were still visible. The nerve fibres were replaced by an opaque granular material, which exhibited indistinct circular markings like those of the original fibres, but without any trace of axis cylinder or medullary sheath. Every section showed two or three small bundles of healthy nerve fibres, situated in each case peripherally—i.e., immediately beneath the epineurium. The epithelial growth could be seen between the nerve bundles, and in many cases lying inside the perineurium. In a very few places scattered epithelial cells were seen between the individual nerve fibres. Sections of the left vagus below the point of compression showed an opaque granular condition of the nerve fibres, with complete loss of axis cylinder and medullary sheath. Here and there a few healthy nerve fibres were seen lying scattered among the degenerate fibres, and not collected into bundles. Both recurrent laryngeal nerves were in much the same state. A few healthy fibres were seen here and there, but there was the same widespread granular transformation of the medullary sheath and axis cylinder, and in places the nuclei of the neurilemma were increased in number, and connective-tissue development appeared to be going on. The crico-arytenoidei postici and the right crico-arytenoideus lateralis were examined, and presented the following appearances. Most of the muscular fibres were normal and distinctly striated, but in all three muscles some of the fibres were thinner than the others and were slightly granular and devoid of striation. Mere degenerate fibres were not numerous in any of the muscles, but were more abundant in the postici than in the lateralis muscle.

The bearing of the present case on the subject of abductor paralysis is obvious. The patient presented at first the appearances of bilateral paralysis of the dilators to which was added subsequently paresis of the constrictors of the glottis. It is difficult to say how long the paralysis of the dilators had existed when the patient was first seen, but we know that this condition was present during the last fortnight of his life, and paresis of the constrictors only developed four or five days before death. The anatomical relations of the new growth found after death quite explain the succession of clinical symptoms. Both vagus nerves were compressed above the origin of the recurrent laryngeal nerves, one of these nerves being also involved in the disease. The first muscles to feel the effects of the gradually increasing pressure of the growth on the motor nerves were the crico-arytenoidei postici, the adductors showing no loss of power till a much later date. It is remarkable that in spite of the very decided pressure on the nerves which existed, the laryngeal muscles showed comparatively so little evidence of degeneration. It must be remembered, however, that some few healthy nerve fibres were found in each recurrent laryngeal nerve. Possibly, too, the complete immunity of both superior laryngeal nerves may have had something to do with the maintenance of nutrition in the muscles, for Exner's investigations teach us that this nerve takes more parts than was previously thought in the innervation of the laryngeal muscles. Krause wishes to exclude cases like that above described so as to avoid the possibility of a direct invasion of the muscles or their terminal nerves by the growth. But, as Rosenbach urges, these cases are specially suited for the elucidation of the question, illustrating as they do the uncomplicated effects of pressure on the nerves. In Rosenbach's, as in my case, the larynx itself was quite free from the growth, and the fact that in his case the necropsy was made by Professor Marchand is an ample guarantee of the correctness of the description which Rosenbach quotes. Cases like these and some of Dr. Semon's contradict Tervaert's assertion that no uncomplicated case is recorded in which paralysis of the dilators passed into complete paralysis of the recurrent laryngeal nerve. Krause lays himself open to a serious fallacy when he compares his experimental studies in animals with the affection known as abductor paralysis in man. Electrical stimulation of the laryngeal nerves of a dog can hardly be said to come within the same category as the degenerative processes set up in the corresponding human nerves by the slowly-increasing pressure of a carcinomatous growth. The same must be said of his attempts to imitate this slow degenerative process by his experiments with the cork. The appearances described in the nerves which he subjected to this treatment are those of acute neuritis, not chronic degeneration. Even granting that he really did produce a tonic contracture of the adductor muscles, which is somewhat doubtful, the difference between the method of production of his artificial contracture and the affections which occasion a similar position of the human vocal cords is so great as to forbid any analogy being drawn between the two conditions. It is strange that the closure of the glottis resulting from electrical stimulation of the nerve ceased when inspiration occurred, in spite of the irritation being maintained, whereas the median position of the cords produced by the pressure of the cork was unaffected by inspiration; and yet in both instances Krause ascribes the approximation of the cords to contraction of the adductors resulting from irritation of the motor nerves.

It will be seen from the various criticisms already quoted that the general opinion is adverse to Krause's views, and, as Professor Fraenkel says, the hypothesis of a primary neuropathic contracture merely adds to our difficulties. The fact that in the case described above both superior laryngeal nerves were unaffected may be claimed by Tervaert as supporting his view. But his theory quite fails to account for cases of abductor palsy dependent on central disease, and cannot therefore be regarded as admitting of general application. Seifert's cases do not throw much light on the subject. For the larynx was only examined anatomically in one case, and the account given is not complete. Whether the laryngeal paralyses described by Seifert can be credited to the influence of lead must remain at present a matter of doubt.

It seems, then, that Semon and Rosenbach have proved their point as to the vulnerability of the abductor nerve fibres, but an explanation is still wanting. It is hard to say whether the vulnerability attaches to the nerves alone or to both nerves and muscular fibres. Dr. Semon, I believe, inclines to the latter view. Simanowski's observations are interesting, as pointing to structural differences in laryngeal muscles. If the terminal motor nerves and their end organs are less abundant in one group of muscles than another, it is easy to conceive that any disease of the corresponding nervous tract, whether central or peripheral, would react more disastrously on this set of muscles than on another group more richly supplied with nervous filaments.

The writer of a leading article in THE LANCET, June 5th, 1886, endeavours to account for the vulnerability of the dilators by a mechanical explanation suggested by Dr. Gowers—viz., that the abductors are inserted at an acute angle into the muscular process of the arytenoid cartilage, and therefore act at a disadvantage as compared with the adductors, which are inserted into the same process almost at a right angle. There are, however, strong objections to the acceptance of this theory, plausible as it seems at first sight.

Mr. Horsley and Dr. Semon[1] have found that if the larynx be excised from animals immediately after death, and the elecrical current be applied directly to the muscles themselves, the crico-arytenoidei postici lose their excitability long before the adductors. Again, some experiments of Dr. Hooper[2] of Boston, published in 1885, and confirmed an

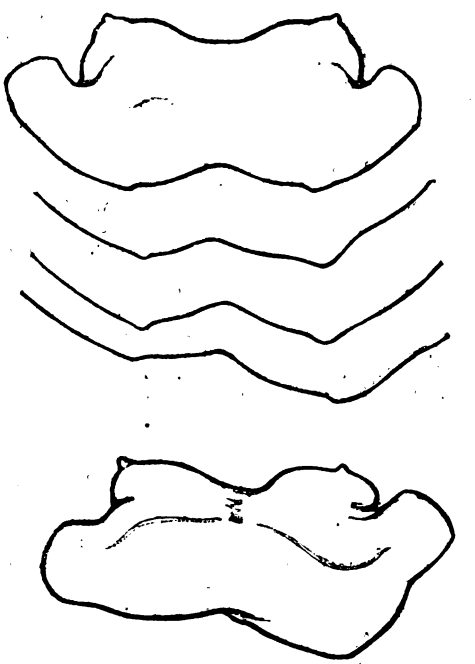
Digitized by Google

amplified by Horsley and Semon,[3] show that the degree of ether or chloroform narcosis determines whether the dilators or constrictors shall react to electrical stimulation of the recurrent nerve. When the anæsthesia was slight, irritation of the nerve produced adduction of the vocal cord; when the anæsthesia was more profound, stimulation of the nerve caused abduction of the cord from the middle line. The differentiation obtains when the peripheral end of the divided nerve is excited, pointing to the action of the anæsthetic being peripheral and not central. Facts such as these do not fit in well with the mechanical explanation suggested above, nor with the idea of the preponderance of the adductors assumed by Krause.

Brook-street, W.

ON LATERAL CURVATURE OF THE SPINE.

BY RICHARD BARWELL, F.R.C.S.,
SENIOR SURGEON, CHARING-CROSS HOSPITAL.



III.

AT some future opportunity, and in some method which affords to me a greater amount of space than can be allotted in the columns of a journal, I shall discuss the exceedingly difficult and much controverted etiology of curves primarily dorsal; here I must confine myself to semeiology and treatment. From whatever cause it may arise, the first advent of dorsal curvature, though occasionally pretty rapid, is in the vast majority of instances insidious and slow. The early changes of form are indicated, not by any aberration in the line of the spinous processes, but by certain alterations due in the beginning solely and entirely to rotation, and this, although the vertebræ as a whole, more especially their bodies, may have considerably deviated. This apparent paradox is due to the fact that by the very act of rotation the spinous processes of the aberrant vertebræ are carried towards the concavity of the curve, and that therefore a certain amount of deviation is, as far as the tips of the spinous processes are concerned, compensated by the rotation itself. But the ribs having a long sweep outwards from the spine, act as indices which show even a very small degree of rotation, a much smaller degree than can be detected by any examination of the spine itself, as, for instance, at the loins.[1] Hence changes of form produced by such twist can be verified by noting just about and outside the line of insertion of the longissimus dorsi tendons, the exaggerated backward projection of the ribs on one side, their diminished protuberance on the other. Moreover, the scapulæ lie on and are supported by the ribs, and must change their position and the direction of their surfaces with any alteration in the planes and forms of the bed on which they lie, hence certain changes in the shape of the shoulders are aids in the diagnosis, and are usually the special point which first attracts the attention of parents, and generally continues throughout the case to be the chief object of their solicitude.

This considered, it will be plain that diagnosis depends on a subtle perception of form, or rather of deviations from natural and healthy symmetry, which I will do my best to explain. Dorsal curvature is usually, though by no means exclusively, to the right. We will therefore suppose, for the purposes of description, a curve convex in that direction. The earliest sign, before any lateral deviation can be made out, and before any obvious change in the position of the scapulæ takes place, is a greater fulness and roundness of the posterior aspect of the right side of the chest, with a certain flatness on the left side around and about the [illegible] of the scapula, as also between that point and the spine. A most useful and instructive method is to inspect the form from above, either by letting the patient [illegible] stool, or better by the surgeon standing on one [illegible] remains erect. Whichever of these two [illegible] the chiefly important point is to look [illegible] spine, noting also the conformation of the [illegible] obtaining, if I may so express myself, a [illegible] patient's *torso*. The annexed series of outlines (see Fig. 7) are diagrams of the forms as thus seen, the head being omitted as likely to confuse the sketches, which were in each instance taken from life. The first is the normal form, showing absolute symmetry of left and right sides—the next three show the progressive changes of the back and shoulders in cases of increasing severity; the fifth depicts in a severe case the changes of back, shoulders, and chest. Now, to explain the last four outlines The depression near the middle of the figure is the place of the vertebral groove. On the left of this (concave side) the outline is slightly flattened, and the slight projection, a little further out (the posterior border of the scapula), lies pretty near the spine and the shoulder blade itself; the line still further out beyond the slight projection is the spine of that bone, looks too directly backward. On the right (convex) side the line from the vertebral groove outward becomes in increasingly severer cases more and more rounded, the posterior costa of the scapula recedes further from the spine, and the hinder surface of that bone looks abnormally outward.

These outlines and description form a key to the back view, in which, by careful lighting[2] these positions, the projections and depressions can be well studied, and the distances of the scapulæ from the spine measured. Moreover, it will be found that the right one sits close to,

FIG. 7.

and pretty firmly on, the ribs; the left lies looser, even a little way off the ribs, so that the surgeon can pass between them—that is, under the venter of the scapula—the ends of his fingers. Hence while the right shoulder is both thick and high, the left one is flat, flaccid, and low. In all but very early cases the line of the spinous processes is curved towards the right, but the proportion between the amount of curvature and the amount of rotation varies in different cases. Soon after the appearance of the dorsal deviation the lumbar spine begins to assume a secondary or compensating curve to the left, and the marks and signs of lumbar curvature, described in my former paper, are superadded to the above changes—namely, the deeper incurvation on one side (left) of the waist, the apparent sideways shifting of the upper part of the figure on the pelvis, the disparity of the two rounded angles between the iliac and the dorsal halves of the trunk. Moreover, about this period—sometimes a little earlier, sometimes a little later—evidence of alteration in the form and position of the ribs may be observed, though a little careful study will show that the anatomical changes must have begun some time before they were clinically perceptible. They are shortly described as follows. The angles of those on the convex side of the

[illegible] Loc. cit.
[illegible] Op. cit., I have shown that the ribs, [illegible] to produce rotation.

[2] A light direct from above has many advantages.

Digitized by Google

spine become more acute, their first part from the head to the angle taking a course too directly backward; the body of the bone from the angle onward is directed too much forward, the whole rib being a segment of too small a curve. On the left (concave) side the first part is directed too little backward, the body runs too little forward—in other words, takes too outward a course; the angle, therefore, is too obtuse, and the whole bone too straight, forming a segment of too large a curve. The changes, therefore, on each side, directly the reverse of one another, are in each instance the continuation further afield of the alterations which I described[3] as taking place on the pedicles and transverse processes. But besides these alterations of form, besides the backward projection of the right and forward yielding of the left ribs other changes of position must be noted—viz., as lateral deviation of the vertebræ becomes marked, and, indeed, as a necessary sequela of that deviation, the thoracic rings become oblique in different directions. The condition may be illustrated thus: suppose seven vertebræ, from the third to the ninth dorsal, to be affected, the second and the tenth being on the median line and straight, the ninth, eighth, and seventh slope over to the right and stand oblique, the sixth, however, is perpendicular, while the fifth, fourth, and third slope back towards the middle line or towards the left, and stand in an obliquity of contrary direction to that of the three lower of our series. Hence, in the left (concave) side the ribs are on the axillo-iliac line packed close together. The middle rib of the series may be taken as normal; but above this they slope too much downward; below it, too much upward. On the right (convex) side the contrary conditions obtain; the basket-work of the chest is too open; the ribs below the most deviated vertebra slope too much downward, those above it too much upward. Thus, to sum up, the ribs undergo three sets of changes—(1) changes of form, (2) changes of position connected with rotation of vertebræ, (3) changes of position connected with obliquity of vertebræ. Naturally, the whole shape of the thorax and of the upper part of the abdomen alters, and many disturbances of function, great loss of health, invalidism, with persistent pain, are thus produced. For the heart is, though often not displaced, yet thrown out of position, the respiratory movements are greatly restricted, the stomach and liver are pressed upon and disturbed. Moreover, the figure becomes considerably, in the worst cases hideously, distorted. I have seen instances in which the ninth and tenth ribs lay within the venter of the ilium well below the crest, and it is not at all unusual to find the angles of the ribs, altered as above described, forming a conspicuous prominence, often taken, previous to closer examination, for the usual "humpback" of angular curvature. These conditions came on slowly in an uncared-for or mistreated case. Thus advanced they are incurable, though relief and alleviation can be afforded; but the very slowness of their advent gives great opportunities for, and shows the high importance of, early and rational treatment, such as I shall describe in my next paper.

ON TWO CASES OF

VAGINAL EXTIRPATION OF THE UTERUS FOR CANCER;

WITH REMARKS ON THE OPERATION.

BY JAMES BRAITHWAITE, M.D. LOND.,

OBSTETRIC PHYSICIAN TO THE LEEDS GENERAL INFIRMARY, AND LECTURER ON DISEASES OF WOMEN AND CHILDREN AT THE LEEDS SCHOOL OF MEDICINE.

IT is now generally admitted that it is unnecessary, and indeed in most cases a mistake, to remove the uterus for cancer of the cervix alone. The tendency of cancer of the cervix is not to spread upwards towards the body of the uterus, but outwards through the thickness of the neck, so as to involve the cellular tissue. It is only when the disease commences near the os internum that it is likely to spread upwards beyond the cervix. This is a pathological fact of the greatest practical importance. It is now, in this country at any rate, generally agreed that it is only in cancer of the body of the organ, or in some cases commencing close to the os internum, that removal of the whole uterus is called for, or even justifiable. In cancer of the cervix not too far advanced for operation it is only necessary to divide the vagina from the cervix all round, and remove as much of the lower portion of the uterus as may be required to cut well beyond the disease. Almost any portion of the uterus short of the whole may be thus removed without opening the peritoneum. At the Leeds Infirmary we have for some time supplemented this operation by removing a further portion of uterine tissue by the use of chloride of zinc. This is followed by great contraction of the cicatrix. This "supra-vaginal amputation of the cervix" might with some justice be called "Baker's operation," as it was first described by Dr. W. H. Baker, of Harvard University, in the *American Journal of Obstetrics* of April, 1882. The mortality from this operation is very low (7·8 per cent.), and it gives equally good results as to freedom from recurrence in cases of cancer of the cervix, and when, or if, recurrence does take place it is very rarely in the stump of the uterus, but in the surrounding cellular tissue. In this paper I shall not again allude to this operation, as it concerns only cases for which it is not sufficiently radical. It is, of course, only possible to treat cancer of the body of the uterus by the removal of the whole organ, and it is now well established that this should be done by the vaginal method (kolpo-hysterectomy) whenever possible, and that what is known as Freund's operation, or removal of the uterus by abdominal section, with its mortality of 72 per cent., should be employed only in exceptional cases.

The two cases which form the subject of this paper were both primary cancer of the body of the uterus. I propose to relate them somewhat briefly, and subsequently to give more fully some details of the operation.

CASE 1.—This patient was thirty-eight years of age. She had had several children, the last being twins, three years before her admission to the infirmary in October, 1885. She was in bad health from loss of blood, which had been going on for a year and a half, in spite of the removal of a polypus in July, 1884. The uterus now again contained a polypus, which, although it had a comparatively narrow neck, grew from a widely extended base on nearly the whole of the anterior wall and fundus. The microscope showed this to be a round-cell sarcoma. The uterus was freely movable, and the disease had probably not extended beyond it.

On Nov. 14th, 1885, with the able assistance of Mr. Mayo, who was then resident surgical officer, and of Mr. Croft, our present resident obstetric officer, I removed the uterus entire per vaginam. Having separated it from its vaginal attachments all round and from the bladder anteriorly, and the peritoneal cavity being opened before and behind, the fundus was retroverted through the posterior wound. I had intended at the same time to push the cervix up through the anterior wound, but found it easier to bring the whole organ out at the vulva, when it lay fully exposed to view, the fundus pointing downwards and the cervix upwards as the patient lay in the lithotomy position. The only attachments were the broad ligaments, the vaginal bases of which had been divided, and these being healthy and elastic there was no difficulty in doing this. Had it not been for an unfortunate accident which now occurred, the operation would have been quickly concluded; but finding that I had not separated the uterus from the bladder sufficiently at the sides of the anterior wound, I widened it by tearing through the cellular tissue a little at each side with the finger. This must have thrown too much strain upon the coats of the bladder, weakened by its separation from the uterus, and a small laceration took place, of which I was not aware until later in the operation. The broad ligaments were now tied in two parts, including, of course, the Fallopian tubes and round ligaments, and the uterus was cut away. It was necessary to tie two vessels in the stumps of the broad ligaments. I now found out the laceration of the bladder, which was about three-quarters of an inch in length and transverse. This was closed by sewing the peritoneum over it to the anterior vaginal wall by a continuous suture, and as it was near the edge of the vaginal wound, it was also included with the peritoneum covering it in the catgut sutures by which the anterior and posterior vaginal walls were alternately brought together. The patient was in such a condition that her death before the conclusion of the operation was possible, and no time was lost which could be avoided, the whole being concluded in one hour and ten minutes. A slow but complete recovery ensued without the occurrence of any unfavourable symptoms. I thought I had made the wound in the bladder quite safe, but a fistula nevertheless resulted. In the following June

[3] First paper, June 25th.

Digitized by Google

the patient was readmitted and the fistula closed. It was very inaccessible, as it could not be pulled down into view like an ordinary fistula, and it was not an aperture, but a small funnel-shaped canal at right angles to, and at the summit of, the vagina.

The patient was heard from thirteen months after the operation. There was no return of the disease, she could retain her urine, and was in fair health.

CASE 2.—Mrs. L——, widow, aged fifty, recently a cook in domestic service; never pregnant. She had suffered from excessive menstruation for four years; no pain until recently. On examination of the abdomen a rounded and somewhat nodulated tumour was felt nearly central, and reaching four inches above the pubes. This was found to be the uterus, the mouth of which was closed. The cervix having been dilated, it was ascertained by the aid of the finger that the growth had the clinical characters of cancer of the interior of the body, extending downwards into the cervix, but not actually implicating the lips of the uterus. This was confirmed by microscopic examination. The organ was fairly movable, but not as freely as in the preceding case. No extension of the disease to the surrounding cellular tissue could be made out.

On March 19th last, assisted by Mr. Harry Littlewood, the resident surgical officer, and Mr. Croft, the resident obstetric officer, I removed the uterus entire per vaginam. After separating the vaginal attachment all round, and separating the uterus from the bladder, and opening the peritoneum before and behind, it was found impossible to retrovert the uterus through the posterior wound owing to its size, and therefore impossible, of course, to bring it down into view as in the first case. It was removed without any particular difficulty in the following manner: Being well pulled down, the broad ligaments were ligated and divided in segments first on one side and then on the other. A Spencer Wells' long-handled needle was used. Each portion of broad ligament divided allowed the uterus to be brought a little lower, in a zigzag fashion. No hæmorrhage occurred from the cut surfaces on the uterine side, although not protected by any ligature. The fundus was then brought down into view, one cornu first, and the Fallopian tubes and round ligaments ligated and divided, and the uterus completely separated and removed. It was now ascertained that the disease had spread up the right tube, and a coil of intestine, which was visible, was seen and felt to be studded with small cancerous nodules. Had it not been for the state of the bowel I should have at once opened the abdomen and removed the tube. The vaginal wound was brought together precisely as in the first case, the peritoneum being in both cases included in the sutures. The only difference was that at each side of the drainage tube were four smaller stumps instead of two larger ones. Each suture fastened in the wound two stumps. The silk-constricting sutures on the stumps were left about two inches long.

The patient recovered without a bad symptom of any kind. The temperature, which had been 102° and over before the operation, fell to 101° and 100° on the two succeeding days. The drainage tube was removed on the fifth day, and all the silk ligatures on the pedicles or stumps came away on the thirteenth and fourteenth days. Of course, the recovery of this patient is only temporary, but her death will be less painful than it probably would have been from cancer of the uterus itself; and meanwhile she has a short reprieve, for she was up and walking about in three weeks and a half, and is now at a convalescent hospital, feeling and looking fairly well. Probably the implication of the tube and bowel was recent, and if the case had been seen earlier, the ultimate result, which is unfortunately too certain, would have been different.

This operation has now, I believe, been performed over 400 times, and the records of a large proportion of these cases are accessible. Almost every conceivable variation in the details of the operation has been made. I propose, whilst giving more in detail the plan of operation followed in the two cases related, to allude to some of these variations, especially as the plan of operation recommended is not that of any one operator, but consists of what appear to me to be the best parts of all, combined so as to form a practical whole, with the addition of some points which, so far as I can ascertain, are new, but seem to me of practical importance and likely to conduce to success. The simpler the operation can be made, consistent with safety from hæmorrhage, the greater will be the success, because these patients are generally in bad health from hæmorrhage, and the duration of the operation is a very important factor. Next to the duration of the operation the most important or equally important object we should have in view is to keep the peritoneum free from contamination with septic and cancerous matter from the uterus.

I notice that the leading idea of most operators has been to avoid hæmorrhage. This I take to be a mistake, for the application of temporary ligatures and clamps, or pressure forceps, takes up time and is generally unnecessary. Forcible dragging of the uterus downwards arrests the circulation, as proved by the absence of hæmorrhage from the uterine side of the divided broad ligaments. It is advisable to prepare the parts by removing with a curette any loose cancerous masses in the neck a few days before the operation and by the use of cleansing antiseptic injections. The patient being in the lithotomy position, and the vagina washed out with rather hot water, for the purpose of preventing hæmorrhage as well as for the sake of cleanliness, in both cases I scratched with a suitable instrument the exact line of the anterior and posterior vaginal fornices. This gives the situation of the incisions, of which the anterior is important. The uterus being now pulled down into view by vulsellum forceps, the posterior incision should be made first. After an aperture is made through the vaginal wall the left index finger is to be passed through to serve as a guide to the scissors with lateral angle, with which the division is completed on each side quite up to the bases of the broad ligaments. Whilst the scissors are used the traction by the vulsellum should be relaxed. Now let traction be again made, and with a scalpel divide the anterior vaginal wall by a semicircular incision in the line of the anterior fornix just to reach the cellular tissue, so abundant here in front of the cervix. Let this incision be prolonged laterally to join the posterior incision at each side, but here the depth of the incision must not be more than one-sixth of an inch, and exactly five-sixteenths of an inch from the cervix.

The next step is to separate the bladder from the uterus, and, being warned by the experience of the first case, in the second I did not use the finger for the purpose of tearing through the cellular tissue. The finger, although sensitive, does not give the nicety required. There can be no better instrument for the purpose than an ordinary uterine scarifier a little bluntened. The small flat blade of this partly cuts and partly tears through the cellular tissue without throwing any strain on the bladder, the walls of which are very tender, being weakened by their separation from the uterus. When the finger is in the anterior wound and a catheter is introduced into the bladder, it will be felt how very thin the bladder wall is. When the peritoneum is reached, it is at once opened by the scarifier, or scratched through by the finger-nail, and the wound is then to be widened with the scarifier from side to side, until a finger in the anterior wound will meet a finger in the posterior wound at each side of the uterus, the broad ligaments only intervening. This is important on account of afterwards ligating the broad ligaments, and it cannot be done unless the posterior wound is made first.

When the anterior wound was made the peritoneum was opened, but when the posterior wound was made in both cases it was left intact, thereby preventing access of blood, cancerous or septic matters. This is a point of the greatest consequence. Before it is opened (which must now be done), the parts must be washed clear of everything. It may be inferred from most accounts of operations that this has not been thought of, but some operators have with the same object made the posterior wound last. The plan I have indicated, however, answers the end required better, for in making the anterior wound, which is a matter of delicacy, it is an advantage to be able to insert a finger into the posterior wound, especially in order to gauge the proper width of the anterior wound, and to steady the parts whilst it is made. The peritoneum is quite loose over the roof of the vagina posteriorly, so that it is actually difficult to open it as it yields before the finger.

Nearly all operators now either bring down the fundus through the posterior wound or through the anterior one. The former plan is obviously the best, because there is more room posteriorly; but I believe both plans are bad, because the cervix is pushed up as the fundus comes down, and by this somersault the cervix with its hurtful discharges has the chance of infecting the peritoneum. To avoid this Mr. Greig Smith of Bristol, who reports a case in THE LANCET of Jan. 1st of this year, even passed a sponge into the peritoneal cavity. The plan of removing the uterus cervix first avoids all risk to the peritoneum. It is the plan followed by Billroth and Martin, but the former ligates the ligaments b

Digitized by Google

mass ligatures—a more difficult and tedious and less secure way than that of ligating them in segments. The plan of bringing the uterus entirely outside adopted in my first case has the advantage of exposing everything fully to view, whilst equally with the plan of removing the uterus cervix first, directly downwards, it avoids the risk of septic infection of the peritoneum. It can only be done when the broad ligaments are elastic and free from any trace of past cellulitis, and when the uterus is not much enlarged. It is not mentioned by any writer on this subject as possible, nor in any account of operations which I have seen is it mentioned, except that Staude has published some cases in which, without the anterior wound being made at all, the fundus was retroverted through the posterior one, the cervix being thus not anteverted, as usual, and then, lastly, the anterior wound was made.

In order to avoid injury to the ureters, their exact distance from the cervix must be borne in mind. This is the merest fraction under half an inch. They are nearest the cervix, quite at the lowest part of the broad ligaments, and higher up three-quarters of an inch from the side of the uterus. This space is very small. It can be made a trifle larger by firmly grasping the broad ligament between the finger and thumb, when the ureter being of firmer structure than the surrounding parts escapes or is squeezed outwards a little. But we have to cut our coat according to the cloth, and it is absolutely necessary for the lowest ligature to be not further from the cervix than five-sixteenths of an inch. The uterus being now removed, we must sponge out the vagina and get an idea of the position and appearance of the wound. The left index is to be passed in to pull down the peritoneum anteriorly and posteriorly. The anterior is most important. With an Emmet's long needle-holder, and one of his needles, which, however, should be made an inch and a quarter in length, and curved slightly (to be had of Mayer and Meltzer, Bond-street, Leeds), a strong catgut suture is to be passed through the edge of the vaginal wall on the extreme right of the wound; then in order through the posterior flap of peritoneum, through two pieces of broad ligament stump (at opposite edges, so that they may not lie superimposed in the wound), through the anterior flap of peritoneum, and lastly through the anterior vaginal wall. These sutures should pass through the stumps at the further side of the constricting silk ligatures, so that when the wound is closed the latter are extra-peritoneal. Two similar catgut sutures at each side of the supra-vaginal wound are sufficient to bring it together and to fasten the pedicles in the wound. A drainage tube should be placed centrally, and fixed to the posterior vaginal wall low down by a suture. It can easily be removed by cutting this suture, without any disturbance or exposure of the wound. The ends of the catgut sutures which bring together the supra-vaginal wound should be cut short, but those of the silk constricting ligatures on the stumps should be left an inch and a half long and lying loosely in the vagina. These will come away in about a fortnight. The vagina, and especially the wound, should now be dusted lightly with iodoform, and the vagina plugged loosely with iodoform gauze. The drainage tube should be cut off so that the end is well within the vagina, lest air should enter the peritoneum. The end of the tube is to be packed round with absorbent wool. One advantage of leaving the silk ligatures on the pedicles so long is that in the event of secondary hæmorrhage the end of each pedicle could be examined separately by sight and any bleeding vessel taken up.

Much attention has been given by writers on this operation to the two questions of whether the peritoneum should be included in the sutures closing the vaginal wound, and whether a drainage tube should be used. A conclusion on these points can hardly be helped by elaborate statistics, for our knowledge of peritoneal wounds is quite sufficient from other sources to teach us that the peritoneum flaps should be brought down and included in the wound; but the result of statistics proves this almost foregone conclusion. There are other ways of doing this, as by using a continuous suture, which is said to be more quickly done, but I think this would seal up the parts rather too firmly. A little capillary exudation should be allowed.

There have been many modifications of the operation, which seem to me should be condemned. Such as removal of the cervix at the commencement of the operation, the use of mass ligatures either as temporary or permanent means of arresting hæmorrhage from the broad ligament, relying upon pressure forceps instead of ligatures for the same purpose, the use of elastic ligatures, putting ligatures on the broad ligaments with the uterus *in situ*, unnecessary ligating the vaginal roof before incising it, and especially leaving the vaginal and peritoneal wounds unclosed. On the other hand, the plan of bisecting the uterus and removing one half first, which has been followed by Müller of Vienna, Zweifel, and by Alexander Simpson of Edinburgh is a modification worth bearing in mind.

In conclusion, my object in this paper has been to try to work out the minute details of this operation, choosing from the various plans which have been previously followed those parts of each which seem most likely to conduce to success. It seems not improbable that the mortality may be considerably reduced. If it is properly done, there seems to me very little for the patient to die from, for the peritoneum can be guarded from sepsis by the methods I have indicated, and hæmorrhage can also be with great certainty prevented. Moreover, if the pedicles are treated extra-peritoneally and peritoneal surfaces everywhere lie together in the wound, it will be shut off almost at once from the general peritoneal cavity. By far the greatest number of these operations have been done on the Continent, and especially in Germany; but this arises from their being done unnecessarily, when supra-vaginal amputation would have given equal security with much less risk. For instance, out of nineteen cases of Fritsch's, sixteen were cancer of the cervix and only three of cancer of the cervix with enlargement of the body. The same proportion holds good with most German operators. In this country the operation has been performed comparatively seldom; but it has been generally confined to suitable cases—viz., cancer of the body or of the neck at its upper part. In Yorkshire it has, I believe, only been done four times, and the two cases related were the only successful ones; but I say this open to correction.

COMPARATIVE EXPERIMENTS BETWEEN THE ACTION OF PAPAIN (FINKLER) AND PEPSINE.

BY DR. D. FINKLER,
PROFESSOR AT THE UNIVERSITY OF BONN.

PAPAIN (Finkler) is a ferment which is manufactured according to my specification from the plant called Carica papaya. It is an albuminous body, which under certain conditions can change albumen into peptone. The conditions which produce this change are very different from those under which pepsine and pancreatine produce the same effect. In order to demonstrate the effect of papain I shall indicate various experiments made by myself which will give an exact insight into the conditions of the effect and also a comparison of the effect of pepsine. For these comparative trials I used a pepsine of known best quality, most of the commercial pepsines being decidedly weaker than the one I used.

I. HAS PAPAIN REALLY A DIGESTING PROPERTY?

Experiment 1.—(*a*) Five grammes raw minced meat, 50 c.c. water, 5 c.c. of a 1 per cent. papain solution (1 gramme in 100 c.c. water). This mixture was put into the oven and kept for twenty-one hours at 38° Centigrade; it was then filtered. The filtered portion contains the albuminous substance of the meat turned into peptone, which is *not* precipitated by nitric acid, nor by ferrocyankalium or acetic acid; it is precipitated by tannic acid. The xanthoprotein and biuret reactions are well shown. The non-peptonised residue of the meat weighs when dried 0·1 gramme; therefore 90 per cent. of the solid portion of the meat has been dissolved in water. Of the albuminous substances of the meat, 87 per cent. were peptonised—which shows a very energetic degree of digestion. (*b*) For comparison, 5 grammes raw minced meat, 55 c.c. hydrochloric acid (0·2 per cent.), and 5 c.c. of a 1 per cent. pepsine solution were treated as above. After twenty-one hours, 70·6 per cent. of the albuminous substance of the meat was peptonised.

Experiment 2.—(*a*) Five grammes meat, 50 c.c. water, 0·5 c.c. of a 1 per cent. papain solution. After forty hours the non-peptonised residue of the meat weighed 0·19 gramme; of the albumen of the meat 77·7 per cent. was peptonised. (*b*) Five grammes meat, 50 c.c. hydrochloric acid (0·2 per cent.), 0·5 c.c. of a 1 per cent. pepsine solution. After forty hours the non-peptonised residue weighed 0·19 gramme; of the albumen of the meat 77·7 per cent. was peptonised.

Digitized by Google

Experiment 3.—(*a*) Ten grammes meat, 20 c.c. water, 1·5 c.c. of a 1 per cent. papain solution. After thirty-six hours, 73·5 per cent. of the albumen of the meat was changed into true peptone. (*b*) Ten grammes meat, 20 c.c. hydrochloric acid (0·2 per cent.), 1·5 c.c. of a 1 per cent. pepsine solution. After thirty-six hours, 18·0 per cent. of the albumen of the meat was changed into true peptone.

Résumé of the Three Experiments.

Ferment.	Digested albumen of the meat.	Time.	Proportion of the quantity of ferment to the meat.	Proportion of the quantity of the meat to the liquid.
Papain (Exp. 1) ...	87·0 %	21 hrs.	1: 100	1:10
,, (,, 2) ...	77·7 %	40 ,,	1:1000	1:10
,, (,, 3) ...	73·5 %	36 ,,	1: 600	1: 2
Pepsine (,, 1) ...	70·6 %	21 ,,	1: 100	1:10
,, (,, 2) ...	77·7 %	40 ,,	1:1000	1:10
,, (,, 3) ...	18·0 %	36 ,,	1: 600	1: 2

Papain therefore shows a more energetic peptonising power than pepsine, and especially so when the proportion of the liquid to the albumen is small—i.e., in the proportion of concentration in which food generally exists in the stomach and intestines. The great variability in the quality of commercial pepsine (some of which will, under the most favourable circumstances, not peptonise more than 20 per cent. of the albumen of the meat) gives papain (Finkler) also the preference, as it is always made of one uniform quality.

The peptonising of hard-boiled egg (egg boiled five minutes and rubbed down) is demonstrated by the following experiments, which were made in an oven at 38° Centigrade.

Experiment 4.—(*a*) Five grammes albumen, 50 c.c. water, 5 c.c. of a 1 per cent. papain solution. After sixty hours in an oven small residue—peptonised 95 per cent. (*b*) Five grammes albumen, 50 c.c. hydrochloric acid (0·2 per cent.), 5 c.c. of a 1 per cent. pepsine solution. After eighteen hours all peptonised = 100 per cent.

Experiment 5.—(*a*) Five grammes albumen, 50 c.c. water, 0·5 c.c. of a 1 per cent. papain solution. After sixty hours all peptonised = 100 per cent. (*b*) Five grammes albumen, 50 c.c. hydrochloric acid (0·2 per cent.) 0·5 c.c. of a 1 per cent. pepsine solution. After eighteen hours all peptonised = 100 per cent.

Experiment 6.—(*a*) Five grammes albumen, 10 c.c. water, 0·5 c.c. of a 1 per cent. papain solution. After forty-five hours peptonised 80 per cent. (*b*) Five grammes albumen, 10 c.c. hydrochloric acid (0·2 per cent.), 0·5 c.c. of a 1 per cent. pepsine solution. After forty-five hours peptonised 40 per cent.

Experiment 7.—(*a*) Ten grammes albumen, 20 c.c. of a 1 per cent. papain solution. After fourteen hours all albumen is dissolved. *Reactions:*—1. Boiling only produces a slight precipitate. 2. Xanthoprotein reaction succeeds very well. 3. Biuret reaction also shows very nice pink (rosy red). 4. Acetic acid and ferrocyankalium give slight precipitate; the albumen is therefore all peptonised = 100 per cent. (*b*) Ten grammes albumen, 20 c.c. of a 1 per cent. solution pepsine in 0·2 per cent. hydrochloric acid. Albumen dissolves slowly after forty-five hours; only 50 per cent. of the albumen is peptonised.

Résumé of the Four Experiments.

Ferment.	Albumen peptonised.	Time.	Proportion of quantity of ferment to albumen.	Proportion of the albumen to liquid.
[illegible] (Exp. 4) ...	95·0 %	60 hrs.	1: 100	1:10
[illegible] ,, 5) ...	100·0 %	60 ,,	1:1000	1:10
[illegible] ,, 6) ...	80·0 %	45 ,,	1:1000	1: 2
[illegible]	100·0 %	14 ,,	1: 50	1: 2
[illegible]	100·0 %	18 ,,	1: 100	1:10
[illegible]	100·0 %	18 ,,	1:1000	1:10
[illegible]	40·0 %	45 ,,	1:1000	1: 2
[illegible]	50·0 %	45 ,,	1: 50	1: 2

[illegible]-boiled egg is better digested by pepsine if [illegible] liquid be large in proportion. As soon, however, as a more concentrated mixture is employed, the superiority of papain is at once evident.

II. WHAT EFFECT CAN BE OBTAINED BY PAPAIN IN THE HUMAN BODY?

a. Concentration of the solution is of first importance.—It is impossible to create in the stomach and intestines such amount of liquid as would be favourable to the effect of pepsine; the conditions, therefore, are very much in favour of papain.

b. Importance of the reaction.—Pepsine acts in the stomach but not in the intestines, as in the latter the reaction is neutral or alkaline. Papain has little effect in the stomach, as the reaction there is acid; when, however, the stomach is neutral or alkaline papain will peptonise, while pepsine will be useless. The degree of acid reaction in the stomach varies greatly, especially in the case of a stomach out of order, in which case the reaction can be so highly acid or alkaline that pepsine would be of no value at all. In the treatment of stomach catarrhs we will, moreover, find that as a general rule the contents of the viscus have been rendered artificially neutral or alkaline by the administration of remedies, so that in these cases pepsine will have absolutely no effect. Papain, on the contrary, will act energetically.

c. Regarding the time available for the digestive ferment to act in the body.—In the case of pepsine this is necessarily very short, as the action ceases when the food enters the alkaline reaction of the intestines. In the case of papain, which can act well in alkaline reaction, the time is practically unlimited, as it continues acting on the food during the whole time it remains in the body.

For all these reasons the conditions for the effect in the human body are far more in favour of papain than of pepsine, and especially as under existing circumstances (high degree of concentration) papain has been shown to act much more energetically; it is only too clear that the preference should be given to papain as a digestive ferment for the treatment of dyspepsia. Besides for dyspepsia, the papain is of great importance in the treatment of diphtheria. Its effective power consists in the circumstance that no free acid need be present in the application, and further, that the moisture of the diphtheritic membranes is quite sufficient to allow the ferment to dissolve the solidified substances of the membranes. No other ferment has so far been able to obtain these results. It is on this account that many competent experimentalists and specialists have lately made observations as to these points. From all these circumstances there is no doubt that in papain we have a ferment which has a great future before it, and it is for this reason that I have made a special study of the manner of preparing the papain. I have had the satisfaction of obtaining the most favourable results from its use in the treatment of disease.

Bonn.

NOTES ON AN OUTBREAK OF BERI-BERI ON THE CHINESE TRANSPORT SHIP *TOO NAN*, STATIONED AT NEWCASTLE-UPON-TYNE.

BY WILLIAM SLATER, M.D., L.R.C.S.E.,
NEWCASTLE-UPON-TYNE, INTERIM SURGEON TO THE "TOO NAN,"
AND
THOMAS OLIVER, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE INFIRMARY, NEWCASTLE-UPON-TYNE.

THE world-wide reputation of Sir Wm. G. Armstrong and Co. as gunmakers draws from time to time the gunboats of many of the nations to the Tyne. Italians, Spaniards, Chilians, Indians, and others have in their turn visited us, and whilst in most their advent and departure have been apparently a source of pleasure to all concerned, such has not always been the case. About eighteen months ago an Indian gunboat arrived in the Tyne in the cold season of the year, and within a very short time several of the sailors died apparently from cold, but the chief symptom of whose illness, it should be remembered, was hæmaturia. None of these cases were seen by the writers of this article. Two months ago the Chinese Government sent over in their transport ship the *Too Nan* 640 sailors to man two new gunboats built on the Tyne. This was not the first

Digitized by Google

visit of sailors belonging to the Chinese navy, nor is it the first during which the harmony of their stay here has been broken by the ravages of death amongst the crew. Two Chinese man-of-war's men died here about two years ago. The *Too Nan* had only anchored a few days in the Tyne, when the remains of three of her sailors were laid beside those of their countrymen in the Elswick Cemetery. Upon the minds of these Chinese sailors, who are by nature strongly bound to each other by ties of affection and friendship, and by whom death away from home and burial in a strange cemetery are regarded as completely destroying all hope for the future, the effect of the death of their comrades was most injurious. Those of them who were ill insisted upon being treated on the transport, in spite of the insufficient accommodation which the vessel offered, for the *Too Nan* had formerly been in the Merchant Service, and was thus ill adapted for the accommodation of such a large number of sailors even in health.

It appears that soon after having put to sea an outbreak of beri-beri, or as it is sometimes called kakké, occurred on shipboard. Two of the twelve sick men died whilst navigating the Red Sea—one on the Red Sea and the other at Suez—and soon after their arrival in Newcastle other three died from the same disease. Eleven were still suffering from beri-beri on the arrival of the ship, and were placed under the care of Dr. Slater, the native medical men preferring that local medical assistance should be procured, as mentioned by your Northern Counties correspondent. The three cases which died were evidently of a very acute character, there being most urgent dyspnœa, dropsy of the feet and legs, feeble pulse in all of them, followed by sudden death from syncope. Unfortunately no post-mortem was allowed. Nearly all the other cases were of a subacute type, and belonged to what Simmons would call the wet variety, so named from the general hydræmic condition of the blood and distension of the general areolar tissue with serum. Anæmia and anasarca are said by Sir Joseph Fayrer to be the general symptoms of the disease, and these, attended by numbness, pain, heaviness, and loss of muscular power, were what presented themselves in all our cases. After a feeling of malaise, which had lasted several days, the sailors noticed that their feet and ankles were swollen, as were also their faces. With this was experienced a sense of great weariness and inability for effort. In addition to the œdema of the legs, they all complained of pain and numbness down the front of the leg and ankle. There was no anæsthesia, nor from first to last did the paresis pass into paralysis. Great pain and stiffness were complained of in the hamstring tendons and the muscles behind the knee-joint. A most trying test for them was to ask them to rise from a kneeling to a standing position. Such exercise was always with great difficulty accomplished, and, in the case of some, was so severe that fainting was nearly induced, whilst in others the muscular effort called forth was such that big beads of perspiration stood out all over. In spite of the peculiar bronzing of their skin, the appearance of the sick men was that of anæmia. Breathlessness on the least exertion was a noticeable feature, and in all of them the pulse was small and feeble, the usual average being 72 to 80. We did not meet with any cases presenting the small quick pulse that Fayrer speaks of, nor in any of them did the temperature rise above the normal. The urine, though high coloured, remained fairly normal as regards quantity and specific gravity, and from first to last remained free from albumen. The furred and white-coated tongue which most of the patients presented did not in the least interfere with the appetite, which continued good all through the period of observation. Brain symptoms may be said generally to have been absent. The same remark applies to the lungs. In all the cases there was distinct evidence of dilatation of the ventricular cavities of the heart; and while no venous hum was heard in any of the cases, in a few of them a well-marked systolic murmur was heard over the pulmonary artery and in two of them a systolic murmur over the mitral orifice, which disappeared under treatment. In all the heart's sounds were feeble. The liver was small, and what struck both of us was the very *marked enlargement of*, and tenderness occasionally felt on pressing upon, *the spleen*. Beyond slight epigastric pain being complained of by one or two, our attention was seldom drawn to the abdomen. The bowels acted normally. The œdema of face and of the feet and legs was one of the most persistent physical signs, but in none of the cases was there ever evidence of the presence of fluid either in pleura or pericardium. A microscopical examination of the blood did not reveal any great reduction in the number of its corpuscles—the white were slightly increased, and the red not only formed rouleaux badly, but were extremely pale, and of very varying size; some larger, others smaller than in health. There was a marked deficiency of hæmoglobin, the colouring matter in some of the cases being present to the extent of only 60 per cent. of the normal.

The crew of the *Too Nan* is composed of two different types of Chinese, each speaking its own dialect, and while not racially distinct, all of them being Chinese, they are yet distinguished from each other by certain marked characteristics. The men who belong to the South of China are short, thick-set, and dark-coloured; those from the north are taller and of much fairer complexion. Now, the interesting point about the epidemic is that the disease attacked the South countrymen alone. Prior to coming to Newcastle these sailors had been to Corea, the projecting portion of the mainland which forms the northern and eastern boundary of the Yellow Sea. Beri-beri is endemic in certain parts of Asia—notably, Ceylon, certain parts of India, Burmah, and the Malayan Peninsula. We had no positive information conveyed to us by the officers of the *Too Nan* of the existence of beri-beri in Corea, but the impression was prevalent amongst the men that the disease had been caught there, and not in the Red Sea, where it first manifested itself with such fatality, and where it is said to be endemic. The fact of the disease being confined to one class—viz., the men who had been to a part of Asia which, though not absolutely known to be infected, is now by the officers regarded as having been so,—the protracted period of incubation, and the uniformity of the symptoms and signs, led us to regard the illness as being of a specific nature; and from the hydræmic condition of the blood and its deficiency in colouring matter and the very marked enlargement of the spleen, we feel inclined to regard beri-beri as a disease of a distinctly malarial character.

All of the cases did well under treatment. What Dr. Slater found of the greatest service was a good nourishing diet, such as beef-tea, eggs and milk, mutton and beef. Brandy and whisky also were allowed—half an ounce to an ounce—three times a day. Medicinally, iron and quinine in some, and arsenic in others, with cardiac stimulants. They were more thickly clad, and kept warmer. They had experienced very changeable weather, and this had, no doubt, greatly influenced the disease. The diet of the ship had consisted of rice, salted fish and pork, and occasionally fresh pork, three times a day. Milk they all dislike. Tea is taken occasionally.

LONDON HOSPITAL.

COMPOUND DISLOCATION OF ELBOW JOINT; EXCISION; SUTURE OF ULNAR NERVE.—REMOVAL OF LOOSE BODY FROM KNEE JOINT.—POST-ACROMIAL DISLOCATION OF HUMERUS; REMARKS.

(Under the care of Mr. WALTER RIVINGTON.)

IN our issue of July 2nd, page 15, we published some cases illustrative of the surgery of the ankle joint, which had been under the care of Mr. Rivington. This week we bring forward examples of injury of the shoulder and elbow joints, also the successful removal of a loose body from the knee joint after incision. The compound dislocation of the elbow joint, though extensive, was rendered more serious by the damage to the ulnar nerve. The result of treatment was very satisfactory. We refer our readers to the account of the case and also to the remarks on it. The post- or sub-acromial dislocation of the humerus is a variety of displacement rarely seen.

CASE 1. *Compound dislocation of right elbow joint; damage to ulnar nerve; primary excision; suture of ulnar nerve; recovery.*—Charles B——, aged fifty-six, was admitted into the London Hospital on July 12th, 1886. He had fallen off an engine, and the right elbow joint had been opened by a jagged laceration on the inner side and behind. The triceps muscle was torn away from its attachment to the olecranon, and the ulnar nerve was exposed for several inches. The internal condyle was crushed; the forearm was displaced backwards; there was no shock. Temperature 99°.—13th: The elbow joint was excised by enlarging the wound on the inner side of the arm. The carbolic spray was used. The triceps was stitched, and a drainage tube was passed through to the outer side. It was feared that the ulnar nerve would lose its vitality in the middle of the exposed portion, but as it was entire it was left untouched. The arm was placed on an angular splint.—14th: Feeling in the hand imperfect; wound looked well.—25th: Passive movement; very little feeling in parts supplied by the ulnar nerve.—29th: Sensation of little and inner side of ring finger quite lost.—Aug. 13th: Spray left off.—Sept. 9th: Wound dressed and looked extremely well. Movement of the arm very free.—Oct. 4th: Some discharge from elbow; swelling of forearm and hand less. Extension, pronation, and supination limited.—13th: Made out-patient.—Nov. 17th: Readmitted for operation on ulnar nerve. As flexion and extension of the wrist and fingers and extension of elbow joint were not free, passive movement was directed to be performed by the dresser.—25th: On pressure over the cut on back of arm a sensation of pins and needles was conveyed to the little and ring fingers.—Dec. 3rd: Ulnar nerve cut down upon and traced downwards. It terminated in a bulbous extremity connected by fibrous tissue to the lower part of the nerve, and the nerve ends were bound down to the bone. The nerve ends were trimmed and united with carbolised silk suture. A straight splint was adjusted in front of the elbow and the arm was slung.—7th: Sensation had returned in ulnar side of ring finger.—Jan. 7th: Wound healed; no sensation in little finger.—14th: Constant current to ulnar nerve.—Feb. 8th: Ulnar nerve exposed again, and found united. On galvanising it the muscles of forearm supplied by it contracted. The nerve was freed from its under attachments, and the wound was sewn up.—12th: Sensation improving.—27th: Scar of incision only left. Galvanism had been continued daily. The skin over the forearm was more sensitive than over the hand.—April 21st: Flexion and extension of forearm at the elbow joint excellent. Pronation and supination could be passively performed for about half the usual range. Sensation was restored as far as the base of the little finger on the inner side of the hand. As the patient had a very useful arm and was anxious to go home he was soon afterwards discharged. The patient was shown to the members of the district branch of the British Medical Association.

Remarks by Mr. RIVINGTON.—In cases of compound fracture and compound dislocation implicating the elbow joint, the choice of the surgeon lies between an endeavour to save the limb without operation by antiseptic treatment, excision, and amputation. As amputation is reserved for the hopeless cases, the real question to be decided is usually whether excision should be performed, or whether the surgeon should trust to nature, aided by antiseptics, for the repair of the injury. In other words, the question lies between securing a stiff or a movable joint, for it is quite doubtful whether at the present day the patient runs any increased risk from submitting to the operation of primary excision in cases of bad compound fracture or dislocation. The advantages of a joint admitting, at least, of flexion and extension are so obvious that the surgeon would always endeavour to obtain the boon for the patient whenever he felt that he was not subjecting him to avoidable danger. The usual method of excision of the elbow joint adopted by surgeons is by the single straight incision through the triceps. There is another, and perhaps a better, method of excision by a single incision on the inner side through skin and fascia only, leaving the triceps untouched, and chiselling through the olecranon process and turning it aside with the attachment of the triceps. In order to obtain room for exposure of the ends of the bones the upper part of the ulna is cleared, the anconeus and fascia covering it being detached as far as may be necessary. The triceps is simply separated from the back of the humerus after the joint has been excised; the end of the olecranon may either be united to the shaft of the ulna by wire, or may be dissected out and the attachment of the triceps stitched to the fascia of the forearm. This was practically the method adopted in the foregoing case, the wound for exposure of the ends of the bones having been already made. The triceps muscle having been torn from its bony attachment, it was impossible to save the end of the olecranon, but the triceps was stitched to the fascia, and the continuity of the fascia on the outer side, the importance of which was well emphasised by Mr. Maunder, was preserved. For some time I have shown this second method of excision of the elbow to the class of operative surgery, but have not had an opportunity of practising it on the living subject, except in the case just related. The chief disadvantage, so far as I can see, consists in a freer exposure of the ulnar nerve than in the method of excision by a single median straight incision. In the latter the ulnar nerve, though felt, may not be seen at all. In the present case the ulnar nerve had been already dissected out for four or five inches, and it is, therefore, no wonder that it lost its continuity after the operation. By secondary reunion it had recovered its functions when the patient was last seen, except as regards sensation in part of the little finger.

CASE 2. *Loose cartilage in knee joint; removal; cure.*—A. L. D——, aged twenty-nine, ship's cook, was admitted in May, 1877. The patient was a Chinaman, and spoke English imperfectly. Eight months before in Japan he was laid up for nine months with some affection of the knee joint, for which some incisions were made in the knee. About four weeks before admission he noticed a lump in his left knee joint which seemed to catch him in walking, and gave him extreme pain. Shortly afterwards his knee joint became very much swollen. Several old scars were seen about his knee joint, which was enlarged and distended with synovial fluid. A foreign body about the size of a small chestnut, very freely movable in all directions, excepting posteriorly, was detected. It slipped freely from one side of the joint to the other.—May 10th: Mr. Rivington fixed the loose body with his fingers on the inner side of the internal condyle, and made an incision about two inches long over the body under the carbolic spray. Two ligatures were applied to bleeding vessels before the synovial membrane was incised. A large quantity of synovial fluid was evacuated, and the foreign body was then removed with finger and forceps. The body consisted of a flat disc of cartilage partially ossified. The synovial membrane was closed by catgut and the skin wound by silk sutures, and antiseptic dressing was applied. The joint filled again with fluid after the operation. The wound healed rapidly without suppuration, and the temperature was normal throughout. The patient was discharged before the end of the month.

CASE 3. *Post-acromial dislocation of the shoulder joint; reduction.*—J. S——, forty-seven, hammer man, was walking along a plank not a foot from the ground, empty handed, when his foot slipped and he fell to the ground. He put his right hand out to save himself, and the palm came in contact with the ground with considerable violence; the elbow joint bent, and he rolled over on to his shoulder. When he got up his hand "felt dead," but thinking that it was only bruising that would pass off, he went on working with his left hand, using the right as little as possible. However, he found the power did not come back to the arm, so he left off work. He experienced considerable difficulty in getting his coat on, and he suspected all was not right. The day following he attended at Miller's Hospital, Greenwich, where two attempts were made at reduction, during one of which the patient was anæsthetised. He was then informed that it was all right now, and was sent away. However, he was unable to use the arm the next day, and continued in this condition until he came to the London Hospital, where he was admitted twelve days after the accident. — April 16th, 1887: Present condition. The whole shoulder appears larger and more rounded than the other, the curves less abrupt. The fold of the axilla is higher on the right side. Behind appearances are more marked. The outline of the shoulder is very prominent and rounded at the back part, while there is some flattening internally. On placing the hand on this prominence and rotating the humerus at the elbow, the prominence is felt to rotate to an equal extent. There was half an inch shortening on the right side, but the left humerus had been fractured at the elbow in 1854, and the measurements are therefore put on one side as unreliable for diagnosis. As regards movement, the patient is able to put his elbow close to his side; indeed, that is the position usually

Digitized by Google

adopted. He is able to cross his arm over his chest, but attempts to raise the arm in front are almost instantaneously checked. Abduction is also impaired. What movements there are are partly of the scapula on the chest. Extension is limited. Abduction is performed by the aid of the scapula to a great extent. The patient is unable to get his elbow behind the vertical axis of the axilla, and is unable to put his hand to his head, the back of his neck, or behind him. Rotation inwards and outwards, especially outwards, are less free than on the left side. Circumduction is also very limited. There is never much pain. Some crackling crepitus is felt on manipulation, but this is obtained with equal ease in elbow and left shoulder. The general health is good. In this condition the patient was shown to the members of the district branch of the Metropolitan Branch of the British Medical Association.—April 22nd: The patient was anæsthetised, and Mr. Rivington reduced the dislocation by means of two jack towels, one to steady the trunk, the other round the arm. With the sole in the axilla, extension was made combined with rotation. The reduction was easy, and took place without snap. The head of the bone slipped out again on rotation inwards and on carrying the arm across the chest. It was, however, easily replaced. The arm was bandaged to the trunk in the position of extension, the elbow was flexed, and the forearm fixed on the chest. In about a fortnight the patient was discharged cured.

Remarks by Mr. RIVINGTON.—The distinction made by Malgaigne of the backward dislocations as comprising two forms—sub-acromial and sub-spinous—appears to me to be just, for the symptoms attending the two varieties are essentially different. In the sub-spinous the flattening of the shoulder and prominence of the acromion are much more marked than in the sub-acromial, indeed, in the latter it may not be marked at all. Looking from the front in the present case it was not easy on cursory inspection to detect any difference between the two sides as regards the contour of the shoulder. Moreover, the elbow appears to be raised from the side in the sub-spinous, and not capable of being approximated, while in the sub-acromial it is applied or can be brought to the side. It is also stated that in the sub-spinous dislocation the axis of the bone is directed backwards, nearly horizontally. In this case the patient could not carry the elbow behind the vertical axis of the axilla. Lastly, the position of the head of the bone is different altogether. For these reasons I maintain that the two varieties should be distinguished. Doubtless they run into each other, but in typical specimens of each there are the marked differences mentioned. I do not think that the term "*sub*-acromial" is a happy one, for the head of the humerus naturally lies under the acromion, and it is from the head projecting backwards behind rather than under the acromion that the variety is produced. Hence, I have named the dislocation "post-acromial" instead of "sub-acromial." A good deal of discussion has taken place in regard to the direction of extension in dislocations of the shoulder, and some have endeavoured to connect their names with the adoption of right-angled traction, vertical traction, and the like. The intelligent surgeon will vary the direction of traction in each case according to the position of the axis of the bone and the special needs of each case. Sometimes one direction of traction will be advantageous and sometimes another, and sometimes a combination of all may be advantageous. In reducing an old dislocation of the shoulder some years ago (the case was published in THE LANCET), I varied the direction of traction by directing my assistant to move in the arc of a circle while extension was fully maintained, and I kept my arm in the axilla to act as a lever. I believe this method to be original, but I have not yet assigned a name to the method. Probably "circumductory extension" would be as good as any.

LIVERPOOL INFIRMARY.

A CASE OF CEREBELLAR ABSCESS; DEATH; NECROPSY; REMARKS.

(Under the care of Dr. MCMURRAY.)

J. W——, aged twenty-two, was brought in a cab to the workhouse on the 25th ult., at 7.30 P.M., and was taken to the waiting-room. When seen he was sitting on a form with his arms crossed, and his chin resting on his chest. His tongue was coated, eyelids drooping, pupils dilated, the right more so than the left. On raising his head, which he did with difficulty, there was internal strabismus of the right eye, which disappeared when he looked downwards. The hearing was more acute on the left than on the right side. He was unable to stand alone, but could do so when supported on each side, and could also walk when supported, but appeared not to know where he placed his feet. When in the upright position his head was thrown back and his neck and back kept rigid. When asked if he were in pain, he said, "Yes," and when asked where, he did not answer, but put his hand to his occiput. He could give no history, and did not answer any questions but the one, he seemed unable to comprehend the other questions put to him, or to collect his ideas. He was sent to the ward, and seen as soon as he was put in bed. He was then throwing his arms and legs about and putting his hands to the back of his head. He would not lie with his head on the pillow, but kept it hanging over the side of the bed. In the course of an hour he became quieter, but refused to swallow, and lay on his back with the eyes closed and his hands behind his head. At 10 P.M. he was unconscious and delirious. At 12.30 he was in the same position, but moved his head from side to side at intervals. He remained in this condition till 5 A.M., when he died.

History.—His friends could give very little information about his illness. He had been with the fishing fleet off Kinsale, and had written to his wife a fortnight previously to his admission here that he could not continue at his work much longer owing to the increasing pain in his ear. This pain he had complained of since November last. No history of discharge from the ear could be obtained. He arrived at Liverpool on the 25th ult., and during the passage remained in his berth, refusing to take anything. On arrival he was put into a cab and driven to the Sailors' Home, and then sent here.

Necropsy.—Body well nourished. No marks anywhere except those of vaccination on the left arm. On removing the skull-cap the vessels of the meninges were congested, and the meninges adherent to the superior frontal gyrus of each hemisphere; a little serous effusion on upper surface of each hemisphere. On removing the brain the vessels on the surface were congested, while the brain substance on section was paler than usual. A portion of the right hemisphere of the cerebellum was occupied by an abscess, which extended from the outer end of the corpus dentatum to the horizontal fissure, the meninges at that spot showing very little inflammation; but a small portion of the petrous bone immediately above the meatus auditorius internus was roughened, evidently from inflammation. The superior petrosal sinus was blocked up by a firm coagulum. No apparent disease of meatus. Chest muscles very dark in colour, right pleura adherent, lung bronchitic on section. Left pleura and lung healthy, but both lungs very dark in colour. Heart normal, but dark in colour. Liver enlarged and friable, dark on section. Gall-bladder contained a small quantity of bile. Spleen enlarged and almost black. Kidneys large and very dark in colour, but apparently good. Bladder contained six ounces of urine. Stomach contained half an ounce of brownish coloured fluid. Lining membrane healthy. A small quantity of fæcal matter in the small intestine; large intestine empty.

Remarks by Dr. MCMURRAY.—Although the history of this case is so imperfect, yet I think there is sufficient to show there had been disease of the ear, which set up inflammation in the petrous portion of the temporal bone, and extended to the superior petrosal sinus, causing thrombosis, that the inflammation extended from that point to the cerebellar meninges, and thence to the white substance of the cerebellum. Retraction of the head with rigidity of the muscles is a sign of cerebellar disease, but in this case the rigidity and retraction were present only when the patient was in the erect position, when sitting the head was bent forward, and when in the recumbent position, although the head was retracted it appeared to me to be due more to the patient being easier with it in that position than to contraction of the muscles, and for this reason when he placed his hands behind his head, he supported the head with his hands, and there was no rigidity of the posterior muscles of the neck. Vomiting is another sign, but there was none in this case, although it might have been present before his admission. Loss of coördinating power was present, but I do not think it could have been of long-standing; and for this reason, that it would have incapacitated him for work much sooner. The very dark

Digitized by Google

colour of the muscles, lungs, kidneys, and other organs was remarkable; it was not due to hypostasis, but affected every portion of each organ, and yet during life there was neither cyanosis nor increased rapidity of inspiration; the weather was not warm at the time, and the post-mortem examination was made within thirty hours of death.

SAMARITAN HOSPITAL FOR WOMEN, NOTTINGHAM.

A CASE OF RADICAL CURE OF UMBILICAL HERNIA.

(Under the care of Mr. H. MICHIE.)

MRS. H—— was admitted with umbilical hernia of ten years' standing, during the last six of which it had been irreducible, and lately the patient said that she had suffered several attacks of obstruction of the bowels, with the symptoms of strangulation, these attacks occurring with increased frequency. The hernia having become strangulated, taxis having failed to reduce it, and the symptoms having become urgent, Mr. Michie performed the following operation. An incision extending from the upper to the lower border of the hernia, eleven inches long, was made down to the sac, which was then also freely laid open. The contents of the sac were the omentum, adherent to the walls of the sac, the transverse colon, the greater part of the ascending and descending colon, and small intestine, which was also adherent at several parts, some of the adhesions being very firm. A knuckle of small intestine at the lower border was constricted and of a slightly livid hue. The hernia could not be reduced. The upper margin of the umbilical opening was freely incised, the whole of the omentum removed after being ligatured in sections, the adhesions of the bowel to the sac separated, and after the bleeding, which from some parts of the bowel was considerable, had been stopped by pressure forceps and sponge pressure, the bowel was returned into the abdomen; the redundant sac and skin were removed, the margins of the umbilical opening were brought together by four deep, stout, catgut sutures, and the skin wound by fine silk. The patient has made an excellent recovery. She was not sick once after the operation; the bowels were moved every morning by a small enema of soap-and-water. The temperature remained normal throughout, and the highest pulse was 96 on the second night.

Remarks by Mr. MICHIE.—I had at first intended to treat the wound as in any ordinary abdominal section, but the patient was so stout that I had not a needle long enough to go through the whole thickness of the abdominal wall, hence the reason for using both deep and superficial sutures. No opiate was allowed either before or after the operation, an important element, I think, in the success of the case. Of course sufficient time has not yet elapsed to say that the cure is permanent, but I can see no reason why it should not be so, or to suppose that this woman will not have as much chance of freedom from a hernia as, for instance, a case of ovariotomy. In the text-books operation for strangulated umbilical hernia when the sac has been opened is said to be attended with an excessively high mortality, and one can easily understand why this should be so in a case where an operation for the radical cure has not been performed; but by carrying out at the same time some such proceedings as were adopted in the present case, we get rid of one at least, and I think two, of the great dangers. These two greatest dangers are, I feel certain, mechanical injury in effecting reduction, and entrance of discharge from the wound into the peritoneal cavity. Having determined upon such an operation, it need not give us much concern to make the incision through the constriction as free as we like. We may make it an inch or two long if we please. Now, with this free incision reduction can be effected with the greatest ease, and so we get rid of the first great danger—mechanical injury. By coaptation of the edges of the peritoneum by means of sutures we produce a radical cure, and at the same time get rid of the second great danger—discharge from the wound into the peritoneal cavity. In a case of strangulated umbilical hernia, where the taxis has failed after a reasonable trial, such a method of procedure as was adopted in this case, and which I have endeavoured to describe, appears to me to be the rational course to pursue; and when done early, before gangrene has taken place, I feel certain that such an operation is as safe as, I believe, it is sound in principle.

Medical Societies.

MANCHESTER CENTRAL MEDICAL SOCIETY.

AT a meeting of this Society on April 19th, Dr. OWEN showed an unusual case of Purpura Hæmorrhagica. The patient, a well-grown girl aged eleven years, had suffered more or less from hæmorrhages for about twelve months. Hæmorrhage from the bowel occurred first. This lasted only a few days, and had not recurred. Epistaxis followed occasionally, but during two months previously to her admission to the Clinical Hospital it had occurred daily, excepting three or four days, during which interval there was bleeding from the left ear. Bleeding from the ear had already occurred upon one day. She had never had purpuric spots upon the body, or swelling of the joints. There had been no bleeding from the mouth. Hæmophilia and purpura were entirely absent from her family history. Her mother was not hæmorrhagic. The girl was not anæmic, and the heart was healthy, and free from murmur. Upon admission she was treated with solution of arsenic, and advised to take freely of oranges and fresh vegetables. She had greatly improved under this *régime*. The special interest in this case rested on the absence of purpuric spots. Dr. Owen pointed out that mucous hæmorrhages, and especially epistaxis, frequently preceded the appearance of purpura, but that in almost every case recorded the spots, sooner or later, occurred as a striking feature of the complaint. The rarity of hæmophilia in the female, and its entire absence from the family history of the patient, excluded that disease from the diagnosis. There was no enlargement of the spleen, no anæmia, and no deterioration of the general health. It appeared impossible to place the case under any other category than that of purpura hæmorrhagica without the spots.

Mr. BISHOP showed a woman suffering from Osteitis Deformans. The bones mainly involved were both tibiæ; the femora, especially the right; the clavicles; the spine; and, but slightly, the right radius and skull. The patient was forty-nine, and had noticed the changes in her limbs for thirteen years. She attributes the results seen to falling over a cat, when, as she believes, the ankle was dislocated. The differences between osteitis deformans and rickets, as also those between it and osteomalacia, were pointed out. The woman shown, with the exception of any marked cranial enlargement, was a very good specimen of this rare disease.

Mr. BAIN read the notes of a case of Corporeal Endometritis, of which the following is an abstract:—L. C——, aged forty-three, married; has had four children and ten miscarriages. No history of syphilis, but several members of her family died of phthisis. Normally the menstrual period lasts about a week, and she loses about ten ounces. The first labour was instrumental; the child died from injuries received during delivery. The perineum was torn, but the laceration was not observed for some time after. The patient attributes all her subsequent illnesses and misery to this accident. Five consecutive miscarriages followed. Her health during this period was most indifferent. After her last miscarriage she had repeated attacks of flooding for some months. Four years ago in March she had a miscarriage. In the following July she again miscarried, and subsequently suffered from an enlarged prolapsed anteverted uterus, for which an air ball pessary was employed. The pessary produced considerable irritation. She has been more or less confined to bed ever since. When she came under Mr. Bain's care, two years ago, she was exceedingly weak and emaciated, and suffered acutely from indigestion. She had continuous backache and severe pain in the right ovarian region, and shooting down the right leg. She could not move in bed without aggravating the pain. Her menstrual periods lasted about a week, accompanied with intense pain and a profuse discharge—about a pint and a half. During menstruation her face seemed altered in appearance, and the prostration was extreme. On examination, the vagina was exquisitely sensitive. No matter how gently the finger was insinuated, it set up a severe aching, which lasted for about four hours. The cervix was enlarged, swollen, and tender, the os slightly lacerated and granular. The body of the uterus was elongated and bulky. The fundus was anteverted. The right ovary was enlarged and intensely tender. The treatment that had been

Digitized by Google

adopted consisted of hot water injections, glycerine plugs, belladonna pessaries, tannin pessaries, lead lotion, borax and alum lotions. Mr. Bain began by applying carbolic acid to the interior of the uterus; occasionally substituting iodine for the carbolic acid. The discomfort set up by these applications increased the prostration and destroyed what little appetite the patient had, so all local applications were stopped, and tonics and ergot prescribed. She gradually improved, and she is now five months advanced in pregnancy. The sensitiveness of the vagina disappeared when the patient became pregnant.

At a meeting on May 17th, Dr. WALTER read a paper upon the Treatment of Post-Partum Hæmorrhage.

Mr. RAILTON read a paper upon the Medicinal Treatment of Epilepsy. He remarked that, although the bromides were adequate to arrest the attacks in most cases during the early stages of the disease, they were often ineffectual in cases of longer standing, or, if not actually ineffectual when administered in moderate doses, had such an injurious effect, both mentally and physically, that it became a question whether the remedy was not worse than the disease. After adducing various cases in illustration, first, of the occasional complete failure of bromide of potassium to arrest the attacks, even when given in doses reaching to an ounce and a half of the drug at a time, and, secondly, of the extreme susceptibility of some constitutions to the depressing effects of the bromides in very moderate doses, he cited instances showing the good effects to be obtained by the combination of belladonna (given in the form of Trousseau's pill) with bromide of potassium, the two drugs combined appearing to be able to arrest the attacks in every case in which they were tried, without having the slightest injurious effect upon the mind or general health. Dr. Railton recommended the pill to be given early in the morning, on waking, in doses commencing with extract of belladonna and bromide of potassium, of each a quarter of a grain, which might gradually be increased for an adult, if necessary, to a grain and a half of each, without any ill effects. The bromide might be given two or three times a day in the smallest doses, which were effectual, never exceeding one and a half drachms in the twenty-four hours.

Reviews and Notices of Books.

Hip Disease in Childhood: with special reference to its Treatment by Excision. By G. A. WRIGHT, M.B., F.R.C.S. With Forty-eight Original Woodcuts. Pp. 246. London: Longmans, Green, and Co. 1887.

HIP DISEASE is a subject of great interest, as much by reason of its pathological obscurity as on account of the difficulty of adequately treating it. It is unfortunately a disease of the poorer classes—in its severer forms almost entirely so. Under "General Considerations," our author says the influence of age is the first and most striking of the predisposing causes. But if this were really the case, would not hip disease be just as common among the better classes and among country-bred children as among the poorer and town-bred children? We are told, however, that "hip disease is enormously more common among the poorer classes, for obvious reasons: worse hygienic conditions, less care if injured, greater liability to injury, and in many cases a worse inherited constitution are sufficient to account for the excess." In this we fully coincide, and think that the "social status" rather than age should stand at the head of predisposing causes.

In discussing etiology and pathology we notice with satisfaction that the author favours the now generally accepted view that hip disease begins in the bone: "An acute, subacute, or chronic inflammation of the upper epiphysis of the femur or its neighbourhood is by far the most common condition." He summarises the published views of most leading surgeons, and discusses them critically. The cases which recover without suppuration he regards as traumatic simple synovitis. Tubercle is held to be the real lesion in the great majority of cases grafted on to or associated with progressive disease of bone, acetabulum, or femur—the latter the more frequent. This section well summarises our present views, and we can recommend its perusal and careful study. It is enriched with a number of drawings illustrative of the disease at the period of excision. The sections on symptoms, diagnosis, and prognosis are all good in their way, though they are founded largely on a hospital experience, and must therefore be taken from this standpoint.

In such a work as this, avowedly written with special reference to treatment by excision, we ought not to be disappointed that the question of treatment by rest has been somewhat disregarded. It is mentioned only to be disposed of in a few lines, and this notwithstanding the obvious fact that the author adopts and approves of the method in certain cases and at certain stages of hip disease. We think it would have been well to have differentiated a little more carefully the class of cases in which rest may be reasonably tried and persevered with. The author's experience is clearly among children of a very poor kind, in whom the reparative power is very low, and in whom disease, especially of bone, when once set up, is with difficulty arrested. As bone disease is shown to be the most frequent cause of hip disease, it follows that in a considerable proportion of cases simple rest in bed alone is inadequate treatment, even when combined with aspiration or incision into the joint. Mr. Wright criticises the results obtained at the Alexandra Hip Hospital, on which the Clinical Society's report and conclusions mainly rested, as somewhat misleading, as giving results such as may be obtained in private practice, but which are impossible in hospital practice. With this view we are inclined to agree. A considerable selection is undoubtedly made and only such cases admitted as are likely to benefit by rest.

We think Mr. Wright would have added to the value of his book if he had contrasted different forms of disease in their initial and early stages. He points out how the statistics of operation are rendered unfavourable by the fact that cases must be included which are operated upon at a stage of the disease when a really favourable issue is impossible by reason of the extent of the disease. What we want is to be able to diagnose early the cases which are likely to progress from bad to worse—cases in which rest is not an adequate treatment, and in which more radical measures will, sooner or later, be required.

The author tabulates 100 cases of excision, and in an appendix gives a summary of the cases. The reader will here find much that goes to justify both the doctrine and practice which Mr. Wright advocates in the body of the work. The book will be found useful and interesting to all those who have much to do with children's hospital work, and to such we cordially recommend it.

On Cancerous Affections of the Skin: a Treatise on Epithelioma and Rodent Ulcer. By GEORGE THIN, M.D. London: J. and A. Churchill. 1886.

IN this monograph Dr. Thin has succinctly given a *résumé* of the history, description, varieties, histology, etiology, diagnosis, and treatment of these neoplasms, and has set forth clearly his own views. He recognises the deep-seated, or infiltrating, and the superficial forms of epithelioma, but holds that the rodent ulcer should be regarded as a disease distinct from the superficial form of epithelioma. He insists that in some cases the differential diagnosis for a time is very difficult, and in some impossible at present; so that such confusion has much obscured the discussions on the nature of rodent ulcer. His views on the latter disease are well known. After pointing out its distinctive clinical features, Dr. Thin describes two markedly contrasted forms of cell grouping, the one uniformly tending to assume a cylindrical form, with giving way and disappearance of the

Digitized by Google

enclosed connective tissue; the other in which the new cells are found in clusters of indefinite shape situated in spaces formed by the separation of the bundles of connective tissue, and in which the groups grow by the cells extending (at first in single file) between the bundles. In the latter form the columns do not penetrate the deeper layers of the cutis, where the bundles are thick and strong. He is confident that the histology of rodent ulcer will come to be recognised as specifically distinct from that of epithelioma, for the cells of the new growth have distinctive characters, and differ from those found in epithelioma in other respects than dimensions. Amongst other things, the cell protoplasm is comparatively scant. The cells never enlarge into the flat horny cells characteristic of epidermic epithelioma, never become "prickle cells," and never form true "nests," whilst there is an absence of the cells of the epidermic type which stain with eosin. Lastly, there is a comparatively small amount of cell infiltration and disorganisation in the connective tissue of the corium. Dr. Thin does not think that any satisfactory proof has been published of, nor has he been able to trace, the origin of the neoplasm from the rete mucosum, hair sheaths, or sebaceous glands; but he has twice observed appearances in the sweat glands that strongly suggest they afford the first point of departure of the growth, though cell masses of new growth were not traced in direct continuity with abnormal sweat glands. The monograph will well repay perusal.

OUR LIBRARY TABLE.

Fairlie Clarke's Manual of the Practice of Surgery. Revised and partly rewritten by ANDREW CLARK, F.R.C.S., Senior Assistant Surgeon to, and Teacher of Practical and Operative Surgery at, the Middlesex Hospital; Examiner in Surgery to the Society of Apothecaries. Fourth Edition. Illustrated by 214 Engravings on Wood. London: Henry Renshaw. 1887.—The late Mr. Fairlie Clarke's manual was well known, and there is no need to discuss now the scope of the work. In preparing a new edition Mr. Andrew Clark had an almost impossible task before him, for we deem it little short of the impossible to present the subject of surgery worthily in the small compass of this manual. But what could be done has been done, and we have no doubt the book will find favour with those students who regard brevity as the essential feature in a text-book.

Disease and Sin: a new Text-book for Medical and Divinity Students. By A MEDICAL MUSER. London: Wyman and Sons. 1886.—This book deals with a great problem; we cannot say that it solves it. The author speaks with a strange mixture of orthodoxy and freedom. He assumes and avers that all disease comes of sin—largely national sin. He would evidently apply capital punishment freely to politicians who for party ends promote petty questions and neglect great national measures for the preservation of children from inherited disease and other avoidable causes of death. He prefers the account of the Creation given in Genesis to all the speculations of Darwin. His estimate of Darwin is not satisfactory, proceeding largely on very doubtful phrenological data, charging Darwin with a lack of modesty, which appears to us more in the accuser than the accused. His main proposition that disease comes of sin is an old one, and, but for the memorable rebuke it received from the Great Teacher concerning the man that was "born blind," might be allowed to pass as a good general proposition with many most perplexing exceptions. The book is a very readable one, and carries the reader over much ground in morals, medicine, and legislation. The author condemns and praises with great freedom. He assumes much. He sometimes theorises in a most unscientific way, and passes from one question to another very incoherently. Some of his "practical" suggestions are highly impracticable, such as the holding of a coroner's inquest into every case of consumption, and the establishment of local councils. "The most urgent reform at present needed is the formation of a council in every parish, in every street, and in every village or hamlet to guard the people against all physical and moral disease .....All the inhabitants ought to be paraded for inspection before the council,..... and in case any child is found to be imperfect in any respect, a special investigation should be held, and the parents or guardians censured, unless," &c. But, with all its faults and impracticabilities, there is much in the book that may be read with advantage by those who would like to improve the world—notably by parents, legislators, and medical men, to whom the author is very complimentary.

Letters from a Mourning City (Naples, autumn, 1884). By AXEL MUNTHE. Translated from the Swedish, by MAUDE VALÉRIE WHITE. Pp. 289. London: John Murray, 1887.—These letters are from the pen of a Swedish doctor practising in Paris, who was at Rome, enjoying a holiday, in 1884, when cholera broke out with so much virulence in Naples. He immediately started for that city, with which he appears to have been previously well acquainted, to render any aid in his power to the plague-stricken people. He recorded his observations with regard to the condition of the poor and the ravages of the disease in a series of letters which appeared in the Stockholm *Dagblad*, and these have been translated into English and reprinted in their original form. We think it is to be regretted that Dr. Munthe did not carry out his intention of revising and condensing them, as there is necessarily, from the circumstances under which they were written, a considerable amount of repetition. The description he gives of the conditions under which the poor exist in Naples is painful, and must remove any feeling of surprise at the intensity of the epidemic of 1884. "According to the official statistics no less than 128,804 of these people inhabit underground dwellings and cellars. ..... As many as 9846 individuals dwell in Fondaci," which the author describes as "the most ghastly human habitations on the face of the earth." A large number are lodged in "so-called locande, where lodgers are received for the night at two and three soldi a head," and which are frightfully overcrowded; while a fourth and very numerous class "have the starry heavens above them and the sewers beneath them. This is the class of Neapolitan poor who have no home at all." Dr. Munthe speaks in strong but not unmerited terms of the vainglorious laudation bestowed by the press upon the White Cross ambulance, to the exclusion of the medical staff of the town, who were doing their duty quite as bravely. "The perpetual struggle for notoriety, the continual mention in all the newspapers of its own heroic deeds, is so striking with regard to this association that it disturbs the impression of all the great and good work it has actually accomplished." We are afraid it is not the only association of the kind to which the remark is justly applicable. The book contains some touching episodes connected with the author's work among the poor, and will amply repay perusal. Although, as we have already said, the book might have been improved by judicious revision, we have no hesitation in recommending it to our readers.

Die Pathologie und Therapie der Gelenkentzündungen. Von Professor Dr. MAX SCHÜLLER in Berlin. Wien and Leipzig: Urban und Schwarzenberg. 1887.—Dr. Max Schüller has published a short and condensed work on the pathology, etiology, and treatment of inflammation in joints. One of the opening chapters is devoted to a very good and simple classification of these joint inflammations; their causation and symptoms are then briefly dealt with, and finally the methods of treatment are described, not in detail as applied to each separate joint, but rather as to the principles involved. A very good bibliography is appended.

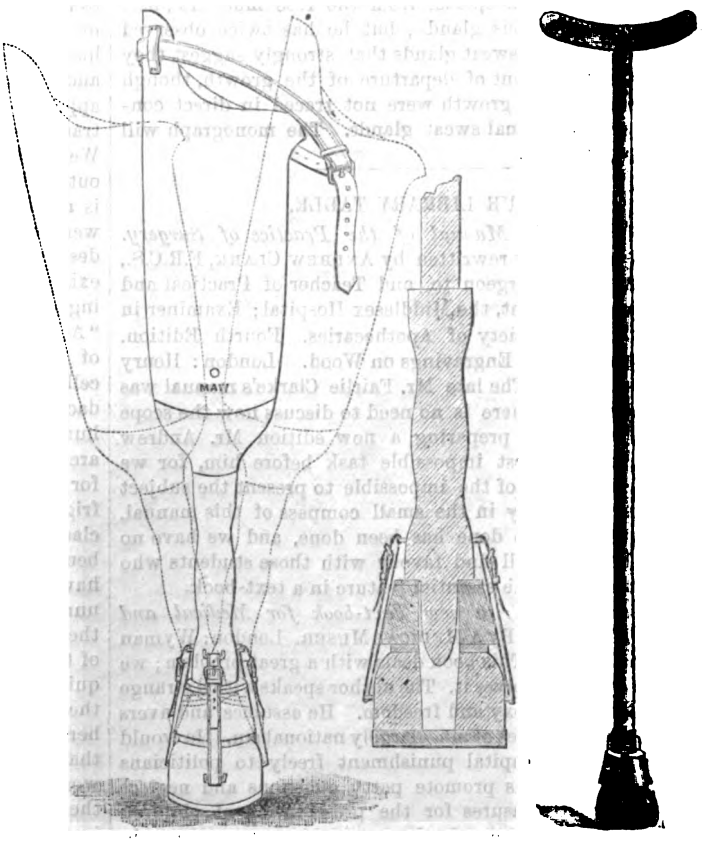
Griffith's Materia Medica and Pharmacy. Third Edition. Edited and partly written by ALFRED S. GUBB, L.R.C.P., M.R.C.S. London: Baillière, Tindall, and Cox. 1887.—Griffith's Materia Medica and Pharmacy has long been a favourite with students preparing for examination. The present edition, edited and partly rewritten by Mr. Gubb, is a great improvement on its predecessors. We have examined it with attention, and find that the information it contains is accurate, and that the whole work has been thoroughly revised. The arrangement is clear, and the facts are concisely stated, and are given in a form which admits of easy reference, whilst the errors are few and unimportant. We are inclined to think that it will be popular with students.

The Cookery Primer for School and Home Use. By AGNES C. MAITLAND. Pp. 158. London: John Hogg. 1887.—This volume contains 121 recipes for the preparation of "very economical dishes, at once wholesome, appetising, and sustaining." It is intended chiefly for the use of girls attending the cooking classes in elementary schools, and for the heads of families in the labour-earning classes. The instructions are clear and easily understood. In the introduction the "hints for hard times" are very good; among these we would specially note one which merits the consideration of cooks in all classes of society. "We English people will try and cook fast, and we make up a fire to cook our dinner quickly in an hour, or perhaps much less, and use more coal in doing that than would have served, if well banked up, to keep in a little fire for three hours, and have cooked the dinner better." We take exception to the recipe for making oatmeal porridge, and would advise the authoress, in the event of a second edition of the Primer being required, to consult some old "Scotch wife" on the subject. The book is one which might be advantageously distributed by those who are interested in the promotion of the comfort of the working classes.



A Manual of Weights and Measures, with Rules and Tables. By OSCAR OLDBERG, Pharm.D., Professor of Pharmacy in the Illinois College of Pharmacy, &c. Second Edition, revised. Chicago: C. J. Johnson. 1887.—We are not surprised that this clear and useful little book has reached a second edition. The author has evidently a preference for the octonary or duodecimal system, but recognises the rapid increase of the decimal, and makes the best of it. His book is a carefully constructed and valuable little manual of metrology, and is well adapted for European as well as for American students. The sections on specific gravity, and the excellent tables with which the pages abound, will save much labour to those who use them.

Notes on the History of Freemasonry. By HENRY SUTHERLAND, M.D. London: John Bale and Sons.—These notes were, the author remarks in his preface, printed some years ago for distribution amongst private friends, and are now published in a larger form, with additions to them, which he believes will render the work more acceptable to his Masonic brethren. The notes do not profess to be exhaustive, but can be recommended as likely to prove interesting to those members of our profession who belong to the great Masonic body.

A NEW FORM OF ARTIFICIAL FOOT.

To the Editors of THE LANCET.

SIRS,—I should be obliged if you will allow me to draw attention to a new form of artificial foot which has been invented by a gentleman, who has been under my care, to suit the necessities of his own case. This foot or base is applicable to any form of artificial leg, and can be adapted to crutches or leg-rests. Its object is to furnish a wide basis of support which will maintain its plane and remain in contact with the ground by its whole surface in inclined positions of the leg. It adapts itself to slight irregularities of surface, and is of great advantage in walking over hilly or uneven ground. In walking it enables the wearer to carry his artificial leg parallel with the sound limb and to continue his stride well in front of the sound foot. It greatly diminishes the jarring and the noisy contact with the ground which is the common characteristic of all but the more expensive artificial legs; and for this reason it lessens the fatigue in walking and the friction at the end of the stump. The base or foot is more or less loose, and its movement is limited by three or more straps attached from it to the stem. Between the stem and the foot is inserted a thick block or ring of vulcanised rubber,

which is retained in place by the straps passing over it and by a peg which projects from the lower end of the stem through the central hole in the rubber block, and a short distance into a cavity in the upper part of the footpiece. The straps are left somewhat loose so as to allow of some movement between the stem and the foot. But any excessive movement is arrested by the tightening up of one or other of the straps. The accompanying illustrations will, I hope, supply the deficiencies of my description.

I am, Sirs, yours, obediently,

July, 1887. THOMAS SMITH.

P.S.—I am informed by Messrs. Maw and Son that the Willis' Leg and Willis' Crutches can be supplied at a comparatively small additional cost, and that the difference in price between these and the ordinary crutches and legs would vary from eight to ten shillings in the case of crutches, and twelve to eighteen shillings for legs.

THE LANCET.

LONDON: SATURDAY, JULY 23, 1887.

FEW classes of men stand in more urgent need of an annual holiday than the members of the medical profession. Their work is very constant, very exacting, always anxious, often in the highest degree laborious and harassing. Just in proportion to the scantiness of their daily leisure is the necessity for an adequate annual rest. Yet this necessity is but too commonly overlooked or trifled with, and not rarely the doctor works on year by year until an imminent failure of health compels the adoption of a practice which might at an earlier date have proved both a source of much pleasure and an efficient prophylactic against premature breakdown. How often do we inculcate upon our patients the folly of working on until the overwrought machine gives way at some point; how commonly does our practice belie our precepts. No doubt the difficulties which beset the medical man in arranging for a holiday are in many respects peculiarly embarrassing, and the busy practitioner is tempted to think that the rather chequered pleasures of a hastily snatched holiday are dearly bought at the cost of the unusual worry and vexation which sometimes ensue upon his return home. But to argue in this way is to follow a short-sighted philosophy. The man who wishes to make the most of his powers and to give himself the chance of long life must learn to rest, and to rest betimes, before body and brain have suffered irremediable damage. Work is but one side of life, rest and amusement form the other, and each is essential for the man who would be

"In se ipso totus, teres, atque rotundus."

If the annals of medical holidays were faithfully recorded, we suspect there would be some curious revelations. Everyone knows the story of the 'bus-man who always spent his holiday on the box of a fellow 'bus-driver, and it might easily be paralleled by instances of medical men who leave the routine of daily practice only to maintain the old associations by attending the clinique of some distinguished metropolitan or continental physician. We are far from entirely condemning this practice; yet it lacks one essential of a perfect holiday—viz., change of mental habit as well as of physical environment. The same objection might be urged against another favourite form of medical holiday, otherwise commendable—viz., attendance upon one of our periodical congresses and associations. Such a holiday has the great advantages of affording the means of interchange of ideas with our medical brethren, of stimulating professional zeal, and of forming or renewing valuable friendships; but, except incidentally, it does not afford much mental distraction or intellectual refreshment. We would urge our brethren in arranging for such congresses to moderate their professional zeal, to limit the output of scientific material, to encourage the social aspects of such gatherings, and to allow ample intervals for rest and physical recreation. By such means these periodical assemblies may serve many useful ends, and more nearly approximate to the ideal of a perfect holiday.

The medical holiday is characterised more commonly by activity than by rest. Medical men pursue for the most part an unresting life and their holiday usually partakes of this strenuous character. We know a provincial physician in extensive practice whose daily life is one of unremitting toil, and whose favourite practice it is to escape for a few days to London, and amuse himself by simply walking about the streets. It is a serious question, however, whether such a form of holiday is a practice to be imitated, or rather an evidence of abnormal mental restlessness to be combated and overcome. Yet we think that for the most part medical men do not take to a holiday of idle dawdling at a watering-place or spa, and that, if the general health be fairly sound, the holiday tour is rather to be recommended. It will be a great additional advantage if the tour consist, not of aimless posting from cathedral to picture-gallery, but of a visit to a locality possessing some features of medical interest. Auvergne, with its celebrated spas, Mont Dore, Royat, and La Bourboule; the Rhine, with Wiesbaden, Ems, and Homburg; the Pyrenees, with Luchon, Cauterets, and Bagnères de Bigorre; the Alps, with the consumptive sanatoria, Davos, Wiesen, St. Moritz, and Maloja—such are a few out of the many districts which might be indicated with favour. At such places the medical man will be sure of pleasant professional company, and may without conscious mental effort acquire a large amount of information which may afterwards be turned to practical account. Year by year patients of the wealthier classes more and more incline to foreign travel as a means of health preservation or health restoration; and the physician who can recommend sanatoria from personal knowledge, and not from mere vague hearsay statements, is sure to find his advice practically beneficial and proportionately esteemed. The observations and inquiries which the medical man may institute upon such a tour have the double advantage of being of real professional utility, while at the same time they are sufficiently removed from the ordinary groove of his daily home routine to constitute a means of genuine intellectual distraction. He must be prepared to receive much conflicting evidence, and to hear many statements not purely disinterested, as the battle of the health-resorts waxes daily more fierce, and derives an additional bitterness from the fact that it is a real struggle for existence. Yet amid the din of jarring claims the intelligent observer may always learn much that is worth knowing. To hotel-keepers, guides, cicerones, *et hoc genus omne*, he will, of course, turn a deaf ear; local medical men would be more than human if their prepossessions and interests did not occasionally warp their judgment; but in the large numbers of visitors at health resorts there is always to be found an intelligent jury daily sitting in judgment upon the merits of each locality, and quite ready to impart their conclusions to the inquiring stranger. Such evidence is no doubt individually of small worth, but its cumulative value may be considerable. The results of treatment are freely canvassed at health resorts, and cannot be effectually hid. Then, again, the medical tourist can easily satisfy himself regarding such vital points as water supply, drainage, hotel accommodation, objects and scenes of interest, facility of access, &c.

To the medical man who desires a really restful holid-

Digitized by Google

nothing is better than a yachting cruise, if it can be obtained under conditions favourable to comfort. No doubt an indifferent ship, persistent bad weather, or obstinate sea-sickness may rob it of all satisfaction and utility, but apart from such unhappy accidents it is of great value. Very pleasant forms of this species of holiday may be secured by cruises round the British Islands, to the fjords of Norway, or to the shores of the Mediterranean. In this way shelter from exceptionally bad weather may be obtained at will, and the tedium of the sea may be varied by occasional excursions on land. As regards sea-sickness, we must own that it still remains an *opprobrium medicinæ*. There is no drug, in our opinion, which can be relied upon to exercise any certain influence in restraining its onset or shortening its course, and medicinal treatment seems usually hurtful rather than the reverse. Bromides, nitrite of amyl, chloral, chloroform, and a host of other remedies enjoy, or have enjoyed, a short-lived and precarious popularity, but few practical men feel any real reliance upon them. Probably the best line of treatment for anyone of known susceptibility to the malady is somewhat as follows: Let him before embarking eat a full meal largely composed of meats and bread; let him assume the recumbent position immediately on going on board, and use freely some sweet-smelling substance to combat the evil odours so common on shipboard; let him fix a flannel bandage round the abdomen, and draw it as tight as possible. If these measures fail to prevent the onset of the affection, some acid fruit should be sucked when nausea first threatens. All stimulants are hurtful at this stage. If there has been a severe bout of sickness, the patient should be carried on deck, placed upon a reclining-chair, and encouraged to eat some lean meat and bread. If there be severe suffering and great prostration, iced champagne is the best remedy.

We have only glanced at a few of the possible forms of medical holiday. Many medical men know their own tastes and needs best themselves, and require no suggestions or advice. Some of these find what they need in a fortnight upon the moors, or in the Engadine, or traversing the wilds of Norway in a carriole. After all, a holiday, like everything else, must be judged by its results. That holiday is best which yields the best fruits, and every general rule has a host of exceptions based on peculiarities of individual taste and temperament. If we return from a holiday physically refreshed, mentally recreated, and with a stored-up host of pleasant associations and agreeable memories on which we can hereafter draw at will, then our holiday has been a success. In proportion as these results are imperfectly attained, or entirely missed, must the doctor's holiday be pronounced a doubtful experiment, or even a complete failure.

THE growing conviction, which in not a few instances amounts to certainty, that infective disease is due to the presence in the organism of pathogenic bacteria, cannot fail to be accompanied by a feeling of impotence to deal with such disease at its root. We are not unmindful of the important measures of prophylaxis which are forcibly suggested by this aspect of the etiology of disease; and it would be easy to adduce evidence of the great stimulus which it has imparted to sanitation. But something more than this is demanded at the hands of those whose aim in life is to heal diseases. Until the term "preventable" comes to be something more than a mere phrase (and in the complex conditions of modern life it is safe to say that the time is far distant when it will be so) we are bound to seek for measures of treatment which shall be effectual in proportion as they attack the foundation of disease. We all know how far the pathologist has outstripped the therapeutist, and there are some who doubt whether the means will ever be available to cope successfully with the minute agencies that attack with too much success the human body, which has to resist their influence as best it may. Pushed to their ultimate limit, diseases that owe their origin to bacterial invasion are the expression of the internecine warfare between the cells of the organism and the foreign intruders. Is it conceivable, then, that by any remedial agents we can hope to destroy the bacterial host, and thus abort the disease, without detriment to the delicate structure of which the body is composed, or the risk of deranging the nutritional processes of its elements? And yet the attempt is made, and will continue to be made, thanks to the rooted belief in the efficacy of medicinal measures. On all sides we hear of bacillicidal methods, but the results are not commensurate with the faith that inspires them or the plausibility of the grounds on which their employment is based. We question whether any real advance will be made in this direction; and yet we by no means despair of a way being found out of the morass. That way lies, we think, in affording to the organism support sufficient to cope with the bacterial hordes—in other words, to strengthen the powers of vital resistance. This is no new doctrine, for it is in perfect harmony with the practice, which was owing so largely to GRAVES, now invariably followed in the treatment of fevers.

That, in addition to our present resources, there are other means whereby the vital resistance of the cells of the body can be stimulated is highly probable. One such method has been lately the subject of experiment, with results that may be worth recounting. It is the method which was introduced by FEHLEISEN in his demonstration that injections of the erysipelas streptococcus could cure lupus, and more widely known through CANTANI in his assertions that inhalations of the bacterium termo could cure phthisis. CANTANI's method has proved a failure, and if it alone were in question there would be no more to say on the subject. But, as Dr. PAWLOWSKY (VIRCHOW's *Archiv*, t. 108) points out, one great error of CANTANI's method was the obvious confusion of many species of bacteria under the head of bacterium termo, and we may add also the reliance solely upon the antagonism of the two organisms, the bacterium termo and the tubercular bacillus, as sufficient to cause the destruction of the latter. Dr. PAWLOWSKY himself demonstrates that it is in no such direct way that one micro-organism can be made to annul the effects of the other. EMMERICH has stated that when animals were inoculated with anthrax bacilli and with erysipelas cocci, either simultaneously or at a short interval, the result was either a prolongation of life beyond the term at which the anthrax bacillus would have caused death, or even a complete neutralisation of the anthrax virus with the recovery of the animal. Seeing that anthrax *per se* is invariably

Digitized by Google

fatal, these statements were sufficiently remarkable to warrant further investigation. Such an investigation was undertaken by Dr. PAWLOWSKY on Professor VIRCHOW'S suggestion, and in addition to testing the counteracting influence of the streptococcus erysipelatis, he experimented in the same way with bacillus prodigiosus, staphylococcus aureus, and FRIEDLÄNDER'S diplococcus pneumoniæ. The experiments consisted mostly in the simultaneous injection of the cultures either beneath the skin or directly into the veins, but sometimes a short interval was allowed to elapse between the primary infection with anthrax and the injection of the neutralising culture. Without entering into the details of these experiments, it may be said that PAWLOWSKY concludes from them in favour of the possibility of curing anthrax by inoculation with other bacterial forms. He found that local anthrax could be cured by subcutaneous injection of micro-organisms at the spot or around it; and that the diplococcus pneumoniæ was the most powerful antagonist to the anthrax bacilli. The next in order was the staphylococcus aureus, which operates in destroying the bacilli by the severe suppuration it excites; but as a remedial agent it is out of the question on account of its virulence. Even the injection of bacillus prodigiosus—a non-pathogenic organism—sufficed in some instances to annul the effect of the anthrax virus, especially if two injections of the former were made and local suppuration excited. Least in efficacy appears to have been the streptococcus erysipelatis—the organism which EMMERICH had made use of in his experiments. As regards the cure of general anthrax, the results of intravenous injection of the above micro-organisms were not so satisfactory. The most favourable results were those obtained by means of the diplococcus pneumoniæ, when this was injected simultaneously with the anthrax bacillus. But even when the injection of the diplococcus followed after an interval upon that of the bacillus, the animal's life was prolonged beyond the term usual in cases of pure anthrax-inoculation. Intravenous injection of the staphylococcus aureus was of no avail; the animals so treated dying either of anthrax or pyæmia, according as one or other of the micro-organisms prevailed. Lastly, similar injections of the erysipelas coccus or of the bacillus prodigiosus failed to prevent the animals dying from anthrax, although apparently prolonging life.

In spite of these somewhat variable results, there yet seems sufficient evidence for the belief that anthrax can be successfully treated by such a method; yet the reason of its success was found to lie less in the directly antagonistic action of one micro-organism upon the other, than in the effect produced upon the cells of the animal body by the introduction of a new micro-organism. This, at any rate, seems to follow from the microscopical examination of the organs of animals so treated. For example, Dr. PAWLOWSKY found in the body of a rabbit which died four days after the intravenous injection of anthrax bacilli, and then of bacillus prodigiosus, bacilli more or less disintegrated within the substance of the large splenic corpuscles, as well as within the cells of the lungs, liver, and kidneys. Indeed, speaking generally, in animals dying as late as four days after inoculation, there were fewer bacilli found outside the cells than within them; and whilst the former bacilli retained their natural characters, the latter were invariably more or less disintegrated. The longer the animal survived the more marked did this state of things arise, so that cells became crowded with bacilli in various stages of degeneration. These appearances were considered as highly confirmatory of METSCHNIKOFF'S doctrine of phagocytes, which in the spleen are represented by "macrophagi," and in other organs by migrated leucocytes. The explanation, then, of the antidotal effect of these bacterial injections would seem to lie in the phagocytes being stimulated to increased resistance, as well as reinforced in number, so that they were the better able to resist the intrusion of anthrax bacilli, and even to overcome them. Such is the latest conclusion arrived at in bacterio-therapy; it is by no means the last, for indeed the subject has hardly yet been studied. Its further development will be watched with interest, although the time for any practical application is probably far distant.

WE are now again approaching the period for those autumnal scientific conferences at which subjects involving important medical considerations are often fully discussed, and we are forcibly reminded of the singular and habitual absence of delegates officially appointed by the British Government when compared with those who represent other European and American States. And yet at some of these conferences the subjects discussed have more importance for this country than for any other. Take, for example, the Sixth International Congress on Hygiene (which is to assemble in September next at Vienna), and the French congress at Havre next month, to which representatives of all naval and mercantile marine interests are invited. At each of these gatherings questions are to be discussed relating to the preparation of international codes for dealing with epidemics, and leaders in the antiquated system of quarantine and allied measures are sent by their respective Governments to secure the acceptance by the congresses of certain definite resolutions laying it down that quarantine is the proper method for preventing the spread of cholera. Dr. PROUST seems to have a roving commission from the French Government in this respect, and he will appear at both the conferences named, having in charge the resolutions which were brought forward in Rome by the French delegation, and which are based upon the assumption that all that Europe needs to save her from cholera is to hold in check for a period of five days all vessels which are suspected or infected. At the last international conference on hygiene the same views were trotted out, no one was delegated from this country to show the fallacies underlying them, and hence conclusions inimical to the true interests of public health were passed on one-sided evidence alone. We do not know what steps Her Majesty's Government are taking to have British views on this important medical question properly set forth at Vienna and at Havre; but we feel confident that the policy of apparent indifference to what Europe at present thinks is not the one best calculated to secure British interests. At Havre, especially, we hope some properly authorised medical delegate will be sent out by the Government, so that British representatives of the shipping

Digitized by Google

interests will not be there unsupported in any effort they may find it necessary to make to withstand conclusions already cut and dried by the French delegates, and which are to be submitted to the gathering as having already been accepted by other scientific and medical congresses. The attempt which was made in Rome in 1885 to impose quarantine in an international form upon Europe altogether broke down because of the attitude of the medical delegates from this country, and the conference having adjourned has never since met to give its sanction to the retrograde views which were set forth. But in the absence of delegates capable of showing the hollowness of mere quarantine restrictions, conference after conference is passing resolutions advocating these restrictions, and the representatives of British shipping stand a good chance, unless they see that the French medical delegates are fairly met by British delegates having knowledge of the medical aspects of this question, to be outvoted in this important subject; and then it will go forth that even a conference dealing with the maintenance of international health from the naval and marine point of view has also advocated the quarantine system. We trust that all who are concerned in opposing unnecessary and vexatious restrictions on commerce, and in frustrating useless attempts to control disease in connexion with shipping, will demand that this country shall be properly represented when these questions are discussed by professedly international gatherings.

THE teaching of Anatomy is a matter of such great importance, that we note with much satisfaction the remarks made on the subject at the commencement of the first business meeting of the Anatomical Society of Great Britain and Ireland held on the 7th of this month. *A propos* of his paper on the Brachialis Anticus Muscle, Professor MACALISTER of Cambridge remarked on the necessity of restricting the teaching of anatomy as much as possible to the points of obviously real value—the points, that is, which have some practical bearing or some morphological or developmental interest. These, he said, should be thrown into relief, and the student's attention fixed upon them, instead of being scattered promiscuously over the whole field, and no clear and defined marks left impressed upon his memory. Professor HUMPHRY, who was in the chair, welcomed these remarks with great pleasure, as forming the best possible introduction to the work of the Society, and hoped they would be duly borne in mind not only by teachers but also by examiners. They were peculiarly appropriate, he felt, at the present time, when the range of subjects of medical education and examination had become so great that it was scarcely possible for the average student to master them in the period that can reasonably be allotted to the preparation for the medical profession. The ill effect shows itself especially in the amount of detail, great in each subject and far too great in the aggregate, which leads to overloading the student beyond his carrying powers, and cramming him quite out of proportion to his digestive capacity, with the necessary result that he is wearied with his work, loses, or perhaps never acquires, interest in it, and forgets nearly as fast as he learns. Nothing, as he remarked, so much as this tends to make our "Jacks" "dull boys," and to swell the rejection lists to the serious dimensions they have now attained. This applies, Professor HUMPHRY said not to medical study alone, but along the whole line of education, general as well as special, and has done more than any other thing to repress thoughtfulness and pleasure in study. That which interests is remembered; and it is the thoughts associated with facts which gives them their interest. Each fact should be regarded as a peg to hang a thought on, and should be regarded as rather a useless article of furniture unless some thought is hung upon it. What is needed is not to burden our students with a mass of facts, but to associate important facts with ideas in such a manner as will impart interest to them, as will make the student perceive the value of them as part of his stock of knowledge, and will enable him to hold them firmly. We entirely concur in these remarks, and are glad that the initiation of the Anatomical Society has had the effect of evoking them. Notwithstanding the greatly increased opportunities for the study of anatomy which have recently been gained, we very much doubt whether the study itself is really carried on better than it used to be. Difficulty, we know, often gives impulse to effort, and scarcity of material enhances the value of it and the care with which it is utilised; but the supply is scarcely yet sufficient to produce any such ill effect. It may be that the students, perhaps from superfluity of assistance, of guidance, and of training, become too much dependent upon others and too little upon themselves. Hence they take less trouble to work out things for themselves, and therefore have less deep and enduring impressions and firm grasp, though they may receive a larger amount of impressions which are superficial and proportionately evanescent; or it may be, as Prof. MACALISTER seems to imply, that there is too much anatomy taught, and too little well taught. Whatever the cause may be, the anatomical status of candidates at the final examinations, when practical knowledge is chiefly required, is such as to demand the serious attention of teachers. The rejections at the primary examinations are startling enough; but of those who have passed this ordeal, far too many fail to retain a sufficient amount of valuable knowledge to meet the final test. We may hope that the new inspectors of examinations appointed by the Medical Council will direct their attention to this point, and be able to furnish some wise suggestions to teachers and examiners, as well as to students, of anatomy.

THE *Echo* of July 15th reports an inquest held by Mr. WYNNE E. BAXTER, touching the death of ELIZABETH RAINE, aged eighty-seven, a single woman, in the St. George's Workhouse, Old Gravel-lane, Wapping, which seems to us worthy of some attention. The deceased went into the workhouse on the 4th inst., in her usual health, according to the evidence of the principal witness, JAMES JOSEPH RAINE, her nephew. On the 10th inst. (Sunday) his wife and daughter called to see the deceased and she was then very ill and unconscious. On the Monday the nephew called. He was not allowed to see the deceased, but was told she would be all right in a day or two. His wife had told him his aunt was bruised and strapped in bed. On inquiring the cause of this he was told by the doctor it was to keep her in bed. On the Tuesday he received a card saying she was very ill

Digitized by Google

and wished to see him. He went and found her unconscious. He was anxious to call in an independent medical opinion, but this, according to the ordinary rules of pauper attendance, was denied. On the 13th he called and found that death had occurred, and was told that a card had been sent to him. One of the inmates, MARY LEARY, deposed to being awakened on the night of Tuesday, the 5th inst., by a noise, and then to seeing the deceased lying on the floor near the fireplace, with her arms across the fender. She tried to help the deceased up, but could not do so, and called in the nurse, who got the patient into bed, and left another woman, an inmate, to watch her for the rest of the night. No explanations from the deceased were obtained. Other evidence continued the history of the case, its removal to the infirmary, where the deceased became delirious and restive, and was gently strapped in bed. Mr. ARTHUR MICKLE, the assistant resident medical officer, stated that the deceased had died from exhaustion, the result of acute senile mania. He did not think that the fall had anything to do with the attack, but that possibly the change from the home to the workhouse might. The nephew asked the coroner if he should not have been allowed to call in an independent medical man. The coroner said he could not allow that question to be argued, and that a patient coming into a workhouse must be treated by the doctor provided by the ratepayers.

Such are the simple facts of this case, which, by the courtesy of Mr. MICKLE, we are able to verify. The evidence seems to have been all given in a straightforward and candid manner, and we do not see that much blame attaches to any individual. But we cannot say that the illustration of the system which the facts afford satisfies us. It is not satisfactory to find that after a patient of eighty-seven has been found near the fireplace, and on the floor and helpless, in the night, she is left to be looked after only by a fellow-pauper almost as helpless as herself. Not only so, but after a nurse had been called and had got the patient into bed, there is no record of the medical officer being summoned.

The case raises, too, an important question to which we often revert—the system of medical attendance in workhouses, and, for that matter, of paupers outside. Here is a patient at the advanced age of eighty-seven under the necessity of becoming the inmate of a workhouse. Is it to be settled that to all the other painful incidents of such a position, and whatever the acuteness and severity of her disease, she is to be denied the advantage of a second medical opinion and the presence of her friends? This is to convert a workhouse into a prison. The coroner, naturally enough, could not allow the time of the jury to be taken up in discussing this question. But it is eminently one for discussion. Our workhouses, especially in London, are becoming more and more the residence of hundreds of poor people, with all the accumulating diseases of age and poverty upon them. Mr. MICKLE not unnaturally assumed that the very removal to the workhouse was a factor in the production of acute mania that was fatal in nine days. And it requires little of either experience or imagination to create the belief that there is a mass of painful and complicated disease in our workhouses, adding another pang to the bitterness of pauperism, which ought at any rate to be the subject of consideration. We will not believe that the ratepayers would refuse to consider some means whereby such sufferers might have the benefit of more than one opinion, either at their cost or that of friends. This is no matter of complaint against medical officers of workhouses, whom we know to be most capable men, and incapable of any unkindness. But do we not all know, in the more hopeless ages and circumstances of life, and when the limitations of art become so painfully apparent, how pleasant it is to see more than one representative of that profession which more than any other is looked to to mitigate suffering and to stimulate hope? We shall not cease to maintain that the thousands who inhabit our workhouses, and their friends, are entitled to know that in the mental and physical disease which afflicts them every resource of medicine and surgery is available for their relief.

Annotations.

"Ne quid nimis."

DEGREES FOR LONDON STUDENTS.

A PETITION has been presented to Her Majesty in Council by University College, London, and King's College, London, praying for the granting of a charter of incorporation "to a body of persons to be appointed as is described in the petition to be a University in and for the London district, having power to grant degrees in the faculties of Arts, Science, and Medicine, with power to add other faculties." The petition has been referred to a committee of the Privy Council, and will be considered on Sept. 1st. This petition has also been sent to the authorities of the London medical schools, who, it is proposed, shall join the medical departments of the two Colleges in forming the Medical Faculty of the proposed University, the faculties of Arts and Science being reserved for King's and University Colleges only. It has also been forwarded to the Royal Colleges of Physicians and Surgeons, with a hope that they may even yet combine in one application. As, however, the delegates of the two Royal Colleges have appointed a sub-committee to draw up a further statement of the claims upon which they urge the granting of a degree in medicine only, it seems highly improbable that any joint action will be taken. Obviously this statement and the draft charter of the joint Royal Colleges should be presented to Her Majesty in Council as soon as possible, for if the petition and charter from King's and University Colleges are to be considered on September 1st, whilst the others are left over to a further date, and the vacation intervenes, a speedy solution of the question, which in the interests of students and the profession is so desirable, cannot be arrived at. It is surely possible that the academical and professional sides of the question can still be fused and a teaching university for London established. Almost every reason that was put forward for the formation of the Victoria University applies to the necessity for a local teaching university in the metropolis.

ARMY ESTIMATES SELECT COMMITTEE.

AT the last two meetings of the Select Committee on the Army and Navy Estimates, Sir Thomas Crawford, the Director-General of the Army Medical Service, was under examination. He considered that the work of the department was sufficient to occupy its staff, and that it was at times overworked. There was no department in the public service in which the mortality was so great. The present rate of pay to medical officers was not too large, as lower rates would not attract a good class of men. It had b considered necessary to increase their pay, as it was f

Digitized by Google

impossible to obtain a sufficient number of candidates to fill vacancies on the terms offered. Under the new system and the present rates of pay no difficulty had been experienced in getting a fair supply of good candidates. He was of opinion that it was a wise measure to allow medical officers to retire, if they wished, at forty-five (it would be more correct to say after twenty years' service), with a pension of £1 per diem. During his time a hundred officers had so retired, but of these, twenty were completely worn out. He believed the proportion of medical officers was about 3 to every 1000 men, and did not consider this proportion excessive, as many duties were imposed upon them which required them to be in constant attendance upon the troops. He was of opinion that all medical officers actually in the field should be military officers, but a considerable proportion of the others should be civilians. He thought the school at Netley was of great value. He pointed out that the health of the British army had improved most enormously during a period of years, and that improvement was continuous and still going on. In India there had been a steady progress in the direction of improving the general condition of the soldier, and this had served to bring about a reduction in the mortality. Such appears to be the general outline of the evidence; when it is published in detail there are several of the questions raised to which we may find it necessary to direct special attention.

MYOPIA IN GERMAN SCHOOLS.

THAT the educational system of our Teutonic kinsmen is responsible for the impaired vision so widely, nay, increasingly prevalent in the Fatherland has till the other day been accepted as a demonstrated fact—accepted, moreover, by the majority of German school legislators as calling for immediate and drastic reform. Dr. J. Stilling, however, the distinguished professor of ophthalmic medicine in the University of Strasburg, joins issue with these authorities, and in a vigorously argued and well-written treatise ("Untersuchungen über die Entstehung der Kurzsichtigkeit"—"Researches on the Origin of Short-sightedness") he seeks to prove—1st, that myopia is not a peculiarly German ailment, any more than it is a specific concomitant of modern high-class culture; 2nd, that myopia is in general no misfortune at all, but in the vast majority of cases a quite harmless deformation of the eye—a deformation not inherited as such, but conditioned by certain anatomical relations of skull development; 3rd and finally, that the school system of his country is not to be lightly made responsible for evils which have not yet been scientifically proved against it. On the other hand, he thinks, the panic into which the indictment has thrown the community, general and educational, the consequent prejudice to school work, and the needless burdening of the State and the taxpayer for the carrying out of crude experiments, constitute a far graver evil than the disadvantages due to myopia itself. Professor Stilling makes an important contribution to the history of medicine when, in support of his first plea, he goes back to Aristotle, and from that physiologist downwards proceeds to show that myopia has in all times been known to cultivated nations as a harmless defect, while in the Middle Ages knights-errant who happened to be short-sighted had helmets specially adapted to assist their vision. Was their defect, he ironically inquired, due to any school system or intellectual over-pressure? Mercuriale, the eminent Italian physician of the sixteenth century, remarked that while Italy had so many short-sighted people the Germans had few or none. "Cur in Italia," he asks, "tot videamus quorum oculi visusque sunt adeo offensi? In Flandria, in Bohemia, in Germania parcos videbitis qui ob visus offensionis cogantur ocularia gerere"; and then he proceeds to account for the phenomenon by the greater devotion to Venus and Bacchus on the part of Italy—an argument which Professor Stilling will not admit. A modern school-reformer in Germany would say that Italy at that time was what Germany has long been—the land of the studious, of those addicted to eye-exhausting pursuits. Professor Stilling, however, is as little satisfied with this explanation as with Mercuriale's, and proceeds to point out that there are two distinct kinds of myopia—the myopia of the diseased eye, with which work of any kind, school-work included, has nothing to do, and the myopia dependent on the formation of the eye, which is itself conditioned by the structure of the eye-cavity, or, in other words, by the cranial development. Donders himself, who opened the campaign against short-sightedness as a product of the school system, maintained that every myopic eye is an eye diseased *(jedes myopische Auge ein Krankes Auge sei)*, has yet had to avow that if he had the power to banish myoia pout of the world he would not exercise it. Near-work *(Nahearbeit)* is, in fact, better performed by this type of eye than by the normal one; but near-work of a far severer kind than any demanded in schools is daily performed by watchmakers, who, as a class, Professor Stilling maintains, are not short-sighted. The Strasburg professor's treatise has yet to run the gauntlet of many rival ophthalmologists, particularly among his compatriots, some of whom have announced their forthcoming criticisms; but his views are well worthy of consideration, not only from the acknowledged eminence of their author, but of the peculiarly pressing nature of the controversy which has evoked them.

THE STATE OF THE THAMES.

AT a recent meeting of the Common Council the present disgraceful and dangerous state of the Thames was once more discussed. Mr. E. G. Wood spoke of a large portion of the river as a huge sewer, and Deputy Saunders, who represents the Corporation on the Metropolitan Board of Works, admitted the evil, and even went so far as to confess his fear that it would never be effectually remedied "until the main drainage outfalls had been removed to a far greater distance down the river." The Board is spending enormous sums for chemicals, and is preparing for a still more enormous expense for permanent works of precipitation at the present outfall. But, as we have often pointed out, no true solution of the difficulty is as yet contemplated. The pertinacity of the Board in resisting the mass of evidence before it, and clinging to the present outfalls, is amazing. All the money that is spent on them will be thrown away, for common sense must inevitably prevail in the end, and a simple and practical remedy has repeatedly been suggested. There is, indeed, but one real remedy that is possible. The strongly expressed advice of the Metropolitan Sewage Discharge Commissioners must, sooner or later, be adopted. The sewage must go down to Canvey Island, or some other suitable spot in Sea Reach, and there be defecated, filtered through the land, and only thrown into the river as a clear and innocuous effluent.

TREATMENT OF DROPSY BY PERMANENT BATHS.

IN the course of a paper *(Berl. Klin. Woch.*, 1887, No. 29); upon the use of permanent baths (at a temperature of about 95° F.), L. Riess, after giving instances of their value in cases of spinal disease and injury, adduces some rather remarkable facts of their efficacy in the treatment of dropsy, whether cardiac or renal. These cases are often complicated with bedsores, erysipelas, and gangrene, for which such treatment would be suitable, but he says that he long withheld it because of the idea that cardiac or pulmonary disease would be a contra-indication to its employment. However, in 1879, in a case of extreme cardiac dropsy (mitral and

Digitized by Google

aortic disease) with considerable erysipelas and cutaneous gangrene of the legs, he determined to try the effect of the permanent bath as a last resort, not without some misgiving lest the immersion should increase the dyspnœa and dropsy. The result proved quite the reverse, for a rapid improvement took place, and when, after having been in the bath a fortnight, the patient returned to bed, the dropsy and other severe symptoms had disappeared. Since then Riess has adopted the procedure in a large number of dropsical cases, and invariably with benefit, the dropsy in most cases (whether renal or cardiac) diminishing within the first forty-eight hours in a striking degree. The quantity of urine is not increased *pari passu*, so that it is suggested that the effect of the permanent bath is to increase the functional activity of the skin, which is contrary to the prevalent notion. The good results obtained in cases of chronic rheumatism so treated are also mentioned, and it is held that the application of the method is practically very simple, it being necessary of course to allow the patient to lie comfortably suspended in a hammock, and to place a thick woollen covering over the bath to retain heat as much as possible. At first it is well to allow the patient to leave the bath at night, but as he gets more used to it he may spend days and nights in it with much comfort both to himself and his attendants.

BONE-SETTERS.

THE untimely death of Mr. Hutton by accidental poisoning has given to a considerable portion of the public press an opportunity for lauding the practice of bone-setters in general and that of Mr. Hutton in particular. To judge from the panegyrics of several leading papers, it would seem that they were bent on the apotheosis of quacks and the canonising of "irregular practitioners." The adage "De mortuis nil nisi bonum" is on most grounds and occasions an admirable one; but, be it remembered, there is a duty owing to the living as well as to the dead, and we should be shrinking from what we consider a paramount responsibility were we to leave unnoticed certain articles recently made public, as we suppose, for the guidance of future sufferers from accidental injuries. Some years ago Sir James Paget gave to the medical profession a record of his experience of "cases that bone-setters cure." Therein may be found a detailed account of sprains, dislocations, and muscular inhibition of movement that may be and often are benefited or removed by the free and ready method of handling habitually practised by bone-setters. The pain and disability caused by a displaced tendon or a locked joint, and the stiffness due to adhesion bands, are appropriately treated by forced movements. At the same time the force requires to be tempered with discretion suggested by the patient's age, constitutional state, and other circumstances, which can only be properly appreciated by one who has received a careful training in surgery and the allied branches of the medical art. By a happy chance rude and rough exertion on the part of the manipulator may suffice to restore lost power and mobility to a crippled limb, and no doubt many such cases occur to the bone-setter. These are the cases that are signalised as triumphs, and find their way into the chronicles of wondrous cures. But what of the failures and disasters that make up the complement of "irregular practice"? We may be sure that their authors do not publish them, and that the victim-patients are only too glad to conceal their chagrin and the consequences of their misplaced confidence. The ancient Greek warriors hung up their shields on return from their wars as votive offerings to the gods for safe deliverance from the perils of battle. A contemporary philosopher gave a wise reproof when he [illegible] are the shields of those who did not return?" The same reasoning in different terms might aptly be applied to the subject under review: Here are the successes, but where are the martyrs to operative audacity? There are few medical institutions that could not furnish a ghastly array of cases where life has been sacrificed or the utility of a limb destroyed by the ruthless treatment of the bone-setter. One example may suffice for illustration. A bone-setter was applied to for the diagnosis and cure of "a bad shoulder." He discovered the inevitable "dislocation" and wrenched the joint, perchance with the strength of three ordinary men. The patient had a malignant tumour of the upper end of the humerus. Unfortunately the ignorant, but trusting, sufferer expects to be told he has a sprain, or a sinew out, or the like. Unhappily, too, for the cause of science and truth, there is too firm a ground for his expectancy. He may be pretty sure that he will be satisfied on this head; and so it is that a thousand and one cases of slight moment are falsely or wrongly described; and when in the course of time nature, in spite of the violence she has received, effects a cure, the result is spoken of as phenomenal. In one instance a renowned provincial bone-setter told a man that his finger was dislocated, whereas to our knowledge it was a case simply of a tendon severed by a knife. The finger was forcibly flexed and extended, a liniment ordered, and the wound healed, but to this day the finger is straight, stiff, and useless, simply because no attention was paid to position. We suppose it is the charm pertaining to mystery that makes the public refuse "to incline to the traditions of experience" or "to the methods of learning." It is difficult to convince a man of the truth against his inclination; and "in spite of the wisdom of sages, men's actions are not governed by their convictions."

A CHOLERA WARNING.

THE Registrar-General's return for the week ending July 16th supplies information which, together with the announcement of maintained cholera in Italy, should be taken as a warning to this country. The deaths which are included in the group of diarrhœa, dysentery, and so-called cholera amounted in London to 526, being 86 above the corrected average. Indeed, as regards diarrhœa, the leap in the last six weeks has been from 9 to 312, including 265 deaths of infants under one year of age. Although the causes of infantile diarrhœa are not yet fully understood, yet one thing at least is known, and that is, that there is a distinct tendency to diarrhœa fatality in districts which are liable to the spread of imported cholera. Under these circumstances, all sanitary authorities should endeavour energetically to cope with every condition tending to exceptional diarrhœa prevalence.

A CAUSE OF TYPHOID FEVER.

DISCUSSING the distribution of typhoid fever in Oldham, Dr. Niven, the medical officer of health, refers to the well-known tendency of this disease to prevail in the colder rather than in the warmer months. In the case of his district he interprets it by explaining that there is a general influence in operation which is for the most part combined with influences acting specially in the winter months. That general influence he describes as either the admission of sewer air into houses by means of defective drain arrangements, or the action of polluted subsoil water, or the two combined. Open doors and windows in summer reduce to a minimum the evils thus resulting. But in the winter, injurious emanations are drawn into dwellings by the aid of internal warmth and of fires, and the foul air is penned in by reason of closed doors and windows. This explanation has often been referred to by various officers of health, and the circumstances described must be regarded as having

Digitized by Google

an important bearing both upon typhoid fever and other conditions of health. Ventilation of houses is as much needed in winter as in summer, and we should like to see a bye-law which requires every house to be built on a site covered with a layer of good cement concrete everywhere adopted and carried out. By such means alone can the suction into dwellings of subsoil air, which is always open to suspicion, be prevented.

SUMMER DRINKS.

A CONTINUANCE of fine weather and of warm sunshine, in spite of the rain upon St. Swithin's Day and occasionally since, implies a continuance of thirst as a necessary consequence of the free perspiration which is likely to attend all muscular movement. In England tropical heat is so rare that we cannot afford to dislocate all business engagements during the middle of the day, and we suffer accordingly; our ceaseless activity is followed by copious perspiration; this in turn by rapid evaporation and its ordinary risks; then, owing to the enormous drain of water from the system by the skin, the various secretions, more particularly those of the mucous and salivary glands, are diminished, and dryness of the mouth and thirst result. There is naturally great temptation to slake thirst whenever practicable, and to re-establish the balance of fluid in circulation. How this can best be effected becomes therefore a question of great importance at the present season. Many persons doubtless increase their discomfort by injudiciously drinking quantities of cold water, which serve to stimulate the sweat glands and so to increase the amount of loss by perspiration. While the "cold-water cure" is to be deprecated, it should not be forgotten that it is equally, if not more foolish to indulge freely in alcoholic stimulants. For the time they certainly allay thirst by stimulating the salivary glands, but after absorption they promote relaxation of the arterioles and increase the rapidity of the heart's action, and are hence followed by a speedy "Nemesis." The cooling influence of acids should be remembered in times of high temperature. The acid employed will necessarily be largely a matter of taste. Most persons would shrink from the use of dilute solutions of citric or tartaric acid, and yet many find relief from a beverage composed of diluted and unsweetened lemon juice. Should cider be found to agree with the digestion, a very pleasant summer drink may be compounded of equal parts of cider and of any pure form of effervescing water, the Hereford or rough cider being, as a rule, more palatable than the sweetened forms. Cold tea has many adherents, but it is worth noting that it should be poured out while still hot, and not allowed to stand to cool in contact with the leaves, since under these conditions, the astringent properties become more completely dissolved, and the tea becomes less palatable and more likely to disorder digestion. Tea has, however, its disadvantages, the chief undoubtedly being the amount of wakefulness produced by it when taken late at night. With regard to iced drinks, it should be borne in mind that the refreshing sense of coolness resulting from their employment in bulk is speedily followed by reaction. This is less felt when a cardiac tonic is employed in this form—as, for example, the iced coffee so commonly provided at afternoon parties. "American drinks," also, are to be employed only in great moderation and with caution, being liable to induce catarrh of the stomach during the period of reaction following the primary chill. Of the so-called "temperance drinks" and of the more common lemonade and ginger beer there is little to be said, provided that the purity of their source can be assured; it is, indeed, on this account that we would urge the employment of the more troublesome but infinitely safer home-made lemonade, prepared with boiling water, and rendered more agreeable by the subsequent addition of any pure effervescing water. Sugar should not be added in any quantity, as it evolves so much heat during oxidation. It is curious to note that the French, who in hot weather so carefully and wisely avoid alcohol, overlook this influence of sugar, and indulge freely in summer drinks of syrups and *eau sucrée*.

ACUTE PROGRESSIVE POLYMYOSITIS.

IN the current issue of the *Fortschritte der Medicin* (1887, No. 14), Professor Unverricht summarises the facts observed by himself and Drs. Hepp and Wagner in three separate cases of the rare affection, primary acute myositis. His own case was recorded in 1881, and he has not met with another since. The case was that of a bricklayer, twenty-four years of age, who was attacked with rheumatoid pains in the thighs and joints. An urticarial eruption on the face was followed by inflammatory swelling of the muscles and connective tissue of the face and limbs. The muscles were extremely tender, so that the patient could barely move. The trunk muscles were affected later, and then the laryngeal and pharyngeal muscles, so that deglutition became almost, and finally quite, impossible. The thoracic muscles were lastly attacked, pneumonia developed, and the patient died from asphyxia after an illness of barely six weeks' duration. The urine had been free from albumen and sugar; there was profuse sweating, and moderate fever. Trichinosis was suspected during life; an exploratory examination, however, of a portion of the deltoid revealed myositis, but no trichinæ. The post-mortem examination confirmed this, nearly all the voluntary muscles being attacked, the extensors of the limbs being most affected. The muscle had a speckled appearance, pale and grey streaks mingled with dark-red hæmorrhagic spots in its substance, which was brittle and œdematous The subcutaneous tissue was also œdematous. The tongue, diaphragm, ocular muscles, and heart were quite intact. The spleen was markedly swollen. No trichinæ were found in a large number of specimens of the muscles, which presented all forms and stages of degeneration, breaking up into fibrils and discs, with cloudy swelling and waxy degeneration, and in places fatty degeneration. The interstitial tissue was infiltrated with round cells, and in places the engorged vessels were surrounded by hæmorrhage. The spinal cord and peripheral nerves were free from changes. Dr. Hepp's case, published this year, was that of a woman, of previous good health, who had for some time felt unwell, when she was attacked with a rash and sore throat. A week later appeared rheumatic pains in the back, and then in the limbs, succeeded by dense œdema. Transitory œdema of the face occurred, leaving behind some swelling of the eyelids. The muscles became tonically contracted and rigid, and there occurred profuse sweating, scanty secretion of urine, insomnia, and increasing weakness. The contraction was so extreme that movements were very limited, and then succeeded cramp and paresis of the muscles of the neck, limbs, and palate. But mobility was retained in the ocular and facial muscles, as well as of the tongue, and the diaphragm, heart, and bladder remained unaffected. The patient died after eleven weeks' illness from intercurrent broncho-pneumonia. In this case also there were splenic swelling and fever. The muscles were pale, like those of the rabbit or of fish, rigid, friable, and infiltrated with serum. Hyaline degeneration of the fibres was found in various stages, but there was barely any interstitial inflammation. In this case the inflammation was almost wholly parenchymatous. Dr. Wagner's case was that of a female cook, thirty-four years of age, the subject of chronic phthisis, who was attacked with pains in the back and thighs, followed by stiffness and tenderness in the neck, shoulders, wrists, and legs. There was slight œdema of the hands, forearms,

Digitized by Google

and legs, which increased to a great degree. An erysipelatous rash appeared on the arms, but passed off together with some of the swelling, so that the arms improved in their mobility. There was considerable fever, and attacks of dyspnœa attributable to involvement of the chest muscles. Death occurred about two months from the onset of pain. Myositic changes were found in nearly all the voluntary muscles. The diaphragm, tongue, ocular muscles, and heart were again unaffected; and no lesions were found in the nervous system. Professor Unverricht points out the close resemblance which these cases bear to one another: in the presence of fever, splenic swelling and œdema, the marked inflammatory nature of the muscular lesion, the preferential involvement of the limb muscles, the progressive course of the disease, which finally involves the muscles of deglutition and respiration, the immunity of the muscles of the eye, heart, tongue, and diaphragm, the occurrence in each case of an urticarial or erysipelatous rash, and finally the mode of death. These characters justify, he thinks, the term "polymyositis acuta progressiva," as descriptive of a distinct disease.

ADVANCE AUSTRALIA.

MANY things have concurred recently to direct the attention of Englishmen at home to the flourishing colony which has already made the Anglo-Saxon race pre-eminent in the southern hemisphere. That attention cannot fail to be arrested by Victoria, and the whole continent may well be content to have its progress measured by the record which Victoria shows. According to the very interesting report which has just been sent home by Sir H. B. Loch, this has been the first among the Australasian colonies to attain to the number of one million of inhabitants. This point was reached in March of last year, New South Wales being then nearly 100,000 behind. But by this time this distinction is no longer peculiar to Victoria, with which the mother colony of New South Wales maintains a keen competition. The rate of growth in a population such as that of Victoria is, of course, considerably higher than the rate of growth in our own country. It is, however, worthy of note that what may be called the domestic increase—that is to say, the increase resulting from excess of births over deaths—is nearly the same at both ends of the terrestrial diameter. It is estimated at 1·3 per cent. for England and at 1·6 per cent. for Victoria. The balance of emigration and immigration, however, reduces this growth with us by about a fifth of 1 per cent., so that the net annual increase is not much more than 1·1 in the 100. The tide which thus flows from our shores sets towards the colonies, and from this source Victoria derives an addition to her numbers equal to that of the domestic increment, bringing up her total annual addition to population to just over 3 per cent. From an analysis of the ages at marriage of the contracting parties, it appears that the habits of the colonists are markedly different from those of the mother country. This difference is, indeed, exhibited by the bridegrooms rather than by the brides. In Australia, as here, the favoured age for women lies between twenty-one and twenty-five years, whereas with us bridegrooms are most numerous at the same period of life, in Victoria the greatest number is found between the ages of twenty-five and thirty. This is easily understood. The men who emigrate are [illegible] single men, and, on the other hand, the men who [illegible] matrimonial alliances have usually little desire or temptation to seek their fortunes under distant skies. It is interesting to note in this connexion that the delay on the part of the men does not appear to involve any diminution of fecundity, the domestic rate of increase being, as we have shown, slightly above the domestic increase in the British islands. But this point requires for its complete elucidation a statement, which the present report does not furnish, of the proportion of the married to the unmarried population. In the record of mortality the reader of Sir H. B. Loch's report is struck by the apparent mildness of some disorders which are among the most formidable scourges of our own population. Thus bronchitis, which at home exacts a larger number of victims than does consumption, is satisfied in Victoria with fewer than one-half of this proportion. In some measure this may be due to the smaller relative number of old persons in the Victorian community, but it is probably attributable in a still larger degree to the more even climate of that favoured land. Its mild July winter counts for much in this connexion. On the other hand, the perils which peculiarly beset vigorous life are much more serious there than here. Thus fatal accidents are twice as frequent relatively in the colony as at home. "But things like that, you know, must be," and will never counteract or seriously impair the progress of an advancing state.

GERMAN LEGISLATION REGARDING POISONOUS COLOURS.

A MEASURE has just received the Imperial assent in Germany which prohibits the use of colours injurious to health in the preparation of articles of food or confectionery. The substances indicated are colours and colour preparations containing antimony, arsenic, barium, lead, cadmium, copper, quicksilver, uranium, zinc, tin, gamboge, coraline, or picric acid, power being given to the Imperial Chancellor to frame detailed regulations as to the tests to be employed for detecting the presence of arsenic and tin. The covering used for holding or wrapping the articles in question are subject to the above general regulations, but exceptions are made for sulphate of barium, coloured baryta lacquers (free from carbonate of barium), chrome oxide, copper, tin, zinc, and their alloys (when used as metallic colours), cinnabar, oxide of tin, sulphuret of tin (when used in mosaic gilding), and colours burnt into the glass, glaze, or enamel of the receptacles alluded to, as well as those used in painting the outside of packages, &c., composed of impermeable substances. The prohibition of the first-named group of noxious ingredients extends (with exceptions generally corresponding with those already named) to cosmetic preparations, or dyes used for the skin, hair, or mouth, as well as to toys, picture books, flowerpot frames, &c. Special restrictions against the use of arsenic are made with regard to printing and lithographic work upon the objects already specified, as well as with respect to wall-paper, carpets, furniture stuffs, paints, &c.; a small maximum quantity being permitted in textile articles.

DRUNKENNESS AT HOME AND ABROAD.

WHEN so many less momentous subjects are the topic for discussion in International and Colonial Congresses, it is gratifying to learn that we have at length such a Congress for the consideration of Inebriety, or what we prefer to call drunkenness. Dr. Norman Kerr delivered the opening address of the first meeting at the Westminster Town Hall on the 6th inst., and a short report will be found in our issue of July 9th at page 70. It is lamentable to find that in all civilised countries this vice—or, as the Congress prefers to call it, this disease—is so prevalent. The most educated nations—Scotland, Germany, France—are as deeply affected as others; and what is sadder still, they are the most blameworthy in carrying the *materies morbi* to uncivilised peoples, which are being demoralised and destroyed by drink. Our own colonies are drinking badly. Men of authority and medical experience say that in Australia our fellow-subjects drink far beyond anything in this country, and beyond their own potations twenty years ago. Chevalier Max Proskowetz de Proskowmarstorff stated at the Congress

Digitized by Google

that in Austria drunkenness was increasing everywhere on a dangerous scale. Dr. Petithan of Liège reported alcoholism in Belgium to be increasing with frightful rapidity. Everywhere there are temperance reformers and noble men who set a splendid example of sobriety and self-denial. The leaders of medicine everywhere by their pathological and medical studies demonstrate the injury done by alcohol to the essential organs of the body—heart, liver, kidneys, brain, and bladder. What is to be done against a disease so deep and a vice so fascinating? Dr. T. D. Crothers thinks that in the United States the time is not far distant when the drunkard will be taken from his home and from the street and quarantined in special hospitals. The inadequate Habitual Drunkards Bill of our own country is about to expire, and a few weak attempts at strengthening it are to be made. But these are not radical remedies. Another suggestion at the Congress was that schoolchildren should be taught the effects of drink on health and national welfare. This is to be commended. Mere general intelligence is not so much a safeguard as might have been expected. Specific information drilled into the young of all the European schools seems loudly called for. The medical profession can do much. Statesmen and Royal Families have a grave responsibility brought home to them by Canon Farrar in a heavy indictment in this month's *Contemporary Review*, entitled "Africa and the Drink Trade," which is sad reading for the countrymen of Livingstone and Stanley. England, Germany—especially Germany—and the United States, the chief representatives of that religion of which Channing said, "Christianity is the mighty power before which intemperance is to fall," are pouring rum and other spirits into Africa as fast as their heartless traders can do it, without restraint from their rulers at home, and against the piteous cry of the hapless people and chiefs of the country, who feel that it will destroy them, and that it is a worse curse than the slave trade, which our fathers did so much to exterminate.

PALMER v. MALLET.

THE judgment of Mr. Justice Chitty in this case, of which we gave our readers a report on the 9th inst. (p. 93), has been made the subject of an appeal, and although the decision of Mr. Justice Chitty has been upheld, the discussion has incidentally raised one or two points of special interest to medical men. Lord Justice Cotton, in delivering judgment, laid down the rule as to the construction of a covenant entered into with two persons in the general sense that if the parties who have a common interest take what may be called divisible shares in the common interest, each of them is, to the extent of his share, entitled to sue upon the covenant without joining the other as co-plaintiff. Were the case otherwise—that is to say, if the parties interested in common had an *indivisible interest*,—they would be unable to enforce it separately. In the present case, Mr. Mallet had entered into an agreement not to "carry on the profession of medicine" in Newtown or within a radius of ten miles round it. The agreement was made with Messrs. Palmer and Hall, who were practising in partnership, and the breach complained of consisted in Mr. Mallet acting as assistant to Mr. Hall after a dissolution of the partnership. In these circumstances it was held that Mr. Palmer had a separate interest in the covenant, which entitled him to an injunction restraining its breach, notwithstanding that his ex-partner, who had of course a common interest with himself in the covenant, was a party to the transaction which he impugned. The case is a strong one, and evidently covers a very large number of others; indeed, it probably includes most of those matters which are in actual practice made the subjects of formal agreement. Another point of some interest upon which a judicial ruling was obtained was the true construction of the expression "carry on the profession," &c. The Court said that the word "profession" was more *emphatic* than "business," and pointed to the nature of the work done rather than to the mode of remuneration. It is abundantly plain that this is good sense, and we are glad to find that it is good law. Etymologically and in common use the word "profession" means that which a man openly says that he can or will do. Thus Cicero: "Ego me omnium provinciarum defensorem esse profitebor." To wrest it from this meaning and make it signify the immediate source of a man's income, so that the practitioner who receives fees is following a profession, while the practitioner who accepts a stipend is doing something other than following a profession, would not only have been a piece of very unlearned folly, but also a gross injustice to those who in good faith had used the term in binding instruments.

AN INFIRMARY FOR THE GORDON BOYS' HOME.

THE Committee of the Gordon Boys' Home have recently issued a special appeal for public assistance in establishing an infirmary in connexion with the new buildings in course of erection at Chobham. We have all along taken a lively interest in the progress of this appropriate and most useful memorial, and we are confident that no apology is needed from us in directing once more the attention of our readers to that part of the arrangements which must possess in their eyes an additional claim to support on account of its professional interest. It is but necessary that an establishment which is intended to accommodate temporarily about 160 boys, and may in the future be extended so as to give house room to a much larger number, should contain within it the means of treating apart and effectually such cases of sickness as may from time to time occur. In view of the possible outbreak of infectious disease it is very desirable that a small separate hospital should form part of its plan of structure, and the application just made in the name of the committee is therefore only reasonable. We learn that £500 has been already subscribed, and we feel sure that an equal sum which is asked for in order to defray the estimated cost of the proposed infirmary will not be sought in vain at the hands of Gordon's countrymen.

DISLOCATION OF THE SEMILUNAR BONE INTO THE PALM.

M. ALBERTIN, prosector to the Faculty of Medicine of Lyons, describes in *La Province Médicale* a case in which the semilunar bone was completely dislocated forwards, and some experiments he subsequently made in order to arrive at an explanation of this rare form of luxation. The only recorded cases of dislocation of the semilunar that M. Albertin has found in medical literature are the five instances collected in Hamilton's work, which include the cases of Messrs. Erichsen, Holmes, and Taaffe. Of these five cases three were palmar and two dorsal dislocations. The Lyons case was that of a workman who fell from a height of about twenty-five feet; he struck the ground with the palm of the left hand, which he had instinctively stretched out. He felt a violent pain, and then became unconscious. When examined at the Hôtel Dieu the semilunar bone was found protruding through the skin of the palm in which a rent had been torn. The bone was movable, being only held by some ligamentous remnants. Professor Poncet enlarged the existing cutaneous aperture and removed the bone. The wound was then disinfected, and a counter-opening made In spite of careful antiseptic treatment the patient succumbed in about a week's time with symptoms of tetanus. Unfortunately, the friends resolutely refused to allow a post-mortem examination to be made. In order to study

Digitized by Google

the conditions under which luxations of the semilunar bone can take place, M. Albertin prosecuted a large number of experiments in Professor Testut's laboratory on eighteen subjects of various ages and of both sexes. He found himself, however, quite unable to produce the dislocation either by blows on the hand when the forearm was fixed, or on the forearm when the hand was fixed, or by violent extension of the hand. The only injury produced was fracture of the lower end of the radius. The conclusion come to by M. Albertin was that the dislocation of the semilunar is, as a rule, prevented by the ligament which binds its palmar surface to the radius, and which, if it remain intact, as it usually does, allows the radius to be fractured rather than the semilunar to leave its place as keystone of the carpal arch. In exceptional cases M. Albertin supposes that this ligament may be very weak, and that then the semilunar may be forced out of its place while the radius remains whole.

KASHMIR MISSION HOSPITAL.

THE native state of Kashmir, or Cashmere, as it is less correctly spelt, is to be congratulated on its possession of a hospital, where much good work, especially of a surgical character, is being done. The medical officers, Mr. Arthur Neve and his brother Dr. E. F. Neve, who are medical missionaries connected with the Church Missionary Society, performed during 1886 no less than 262 major and 596 minor operations, with only two deaths. The affection which may be considered as peculiar to Kashmir, and which has been described by Drs. Elmslie and Maxwell—viz., epithelioma of the abdomen and thigh due to the habit of carrying earthenware pots, or *kangris*, containing burning embers next the skin,—would appear from the report before us to be much less common than it formerly was, as the excisions of these tumours only number twenty-two, whereas several years ago these cases bore a very considerable proportion to the total number of operations. The number of cataracts operated on was twenty-two, of which only three gave unsatisfactory results. The skull was trephined once for epilepsy, the result being some improvement. Stone is not nearly so common in Kashmir as in many parts of the plains. In former years several months would sometimes elapse without a single stone case presenting itself. During 1886 only four cases of vesical calculus were operated on—all successfully,—two by litholapaxy, one by perineal and one by supra-pubic lithotomy. Nerve-stretching was done fourteen times, all the cases being "improved;" twelve of these were cases of leprosy, one was a case of multiple sclerosis, and one of anæsthesia of the limbs. Radical operations for hernia were performed eleven times, complete success being obtained in ten instances. The two fatal cases were a large abscess and a penetrating wound of the abdomen. No abdominal sections were performed.

CONTAGIOUS DISEASES ACQUIRED IN SHAVING.

A CASE which was recently decided in a County Court may serve as a caution to barbers and hair-dressers, who are in danger of forgetting their responsibilities in respect of contagious disease, while it should instruct the public as to some obscure but unavoidable risks to which they are liable. A man who was in the habit of being shaved every Saturday evening at the very modest cost of three-halfpence, was sensible on a certain Sunday of an unaccountable irritation in the skin of his face. He consulted a neighbouring practitioner, who pronounced his trouble to be "parasitic barbers' itch." One form of *sycosis menti*, it will be remembered, is due to the presence of the parasite of ringworm, and, like other cases in which the seats of hair-growth are affected by this troublesome pest, is very intractable. This, doubtless, was the character of the disease in question in the case before us; and the decision of the judge, which was not arrived at without considerable hesitation, held that the barber was guilty of having infected his client by means of a dirty razor, brush, or towel. We confess that this judgment is, to our mind, by no means a clear one. Of direct proof of culpable neglect on the barber's part there was none. At the same time, no other possible source of contagion appears to have been suggested, and certainly the facts that the face was the part affected, and that at the cost a cleanly renewal of shaving materials for each customer was well-nigh impossible, must invest the verdict with whatever support is derivable from circumstantial evidence. If, therefore, we grant that the materials used were not clean, to which of them should blame be specially attached? It seems to us far less likely that the razor was accountable than that either the soap or towel was so, the first-mentioned being so much more easily cleansed. With a view to the prevention of such accidents in future, it seems, therefore, advisable that all barbers should follow the rule already observed by the better class of that fraternity, and in place of using soap in the block form, employ a soap-cream, a little of which can be set apart for each customer. The provision of separate towels and brushes in each case is at least equally desirable, even though it entail an extra halfpenny in the charge.

BRITISH ADMINISTRATION IN WESTERN AFRICA.

IT is told of Zachary Macaulay, father of the distinguished essayist and historian, who was for many years British Governor at Sierra Leone, that his equanimity was never known to be disturbed except when someone ventured the opinion that Western Africa was insalubrious. In spite, however, of the genial Scotchman's championship the unfavourable opinion has continued to this day, and assuredly not without reason. A highly interesting series of reports from the British agents in the West African settlements has just been laid before Parliament, and certainly the state of facts disclosed does but little credit to the British administration of the local government. The following pungent comment, for instance, by Mr. T. D. MacCarthy on the condition of Accra ought not to lie buried in the depths of a parliamentary return. "I cannot help remarking," says he, "and no one can deny, that our system here is an utterly selfish one with regard to the water supply; for whilst the official public are, and, as a rule, always have been, well supplied with pure water for all purposes, the wants of the general public in that respect have been comparatively ignored. . . . . As constituted sanitary officer of this colony, however, and knowing, as I do, the evils in bodily health which accrue to the natives from drinking the foul and brackish water which they do, I earnestly appeal to the Governor's sense of justice and humanity to deal promptly and in a liberal manner with this important question." The urgency of the necessity to which Mr. MacCarthy alludes is irresistibly demonstrated by his description of the bathing pond at Accra. "The water is of a vivid green, turbid, and otherwise filthy." Yet it seems that the native population enjoys no better facilities than these disgusting pools afford. "For the want of public latrines they are compelled to take advantage of the shelter of every bush and old ruin they find at hand; and so, for want of a moderate water supply, the poor creatures are forced to wash their bodies in these stagnant ponds." The only comment which the Governor makes, in transmitting this report, upon the sanitary officer's demand is that some action was taken some time ago towards constructing a rain-water reservoir of a capacity to supply about a pint and a half of water daily to every head of the population. It may afford some measure of the absolutely ridiculous inadequacy of this proposal to say that

Digitized by Google

the people of Calcutta receive fifteen gallons per head per day. We trust that this matter will not be suffered to remain here, but that, by questions in Parliament or otherwise, pressure will be put upon the Government in order to save the British Administration from the disgrace of sitting by with folded hands in the presence of such a dire necessity as this.

THE AMŒBÆ OF DYSENTERIC STOOLS.

DR. O. UPLAVICI, from an extensive series of observations on dysenteric stools, has come to the conclusion that bacteria, though they are to be detected in large numbers and of many varieties in the evacuations of dysenteric patients, are nevertheless not the cause of the disease. He made out nineteen different micro-organisms, but not one of them was constant. It was otherwise, however, with amœbiform masses which were present in each of the sixty cases of dysentery, some of them of the acute and some of the chronic form, which he examined. These amœbæ have been described by various writers. The first observer to notice them appears to have been Loesh of St. Petersburg, who mentions having found them in a case of dysentery in 1875, since which time Leuckart, Koch, Grassi, Cunningham, Normand, and more especially the Bohemian professor, Dr. Hlava, and Kartulis of Alexandria, have paid considerable attention to these curious masses of protoplasm, both of the two last-named observers having recognised the casual relationship of these bodies to the disease. The observations of Professor Hlava were referred to in THE LANCET of March 19th. Dr. Kartulis found amœbæ in every case to the number of 150 in which he examined the stools, and he entirely failed to find them in the stools of patients suffering from other diseases, such as typhoid fever and phthisis. He was unable to cause the amœbæ to propagate in any medium, and he injected them into the intestines of two pigs and a rabbit without result. Professor Loesh, however, had succeeded in getting them to multiply in one dog out of four into which he injected them. Dr. Uplavici has now prosecuted this line of research with better results. He injected fresh stools containing amœbæ into the rectums of seventeen dogs, and in two cases succeeded in producing dysentery with multiplication of amœbæ. In four cats out of six experimented on positive results were obtained, but no effects were produced on eight rabbits, two fowls, and six guinea-pigs. In one case of dysentery "giant amœbæ" were found, which, when introduced into a cat, were found in the stools.

THE PURITY OF DRINKING FOUNTAINS.

A FEW weeks ago we drew attention to the view maintained by several veterinary surgeons respecting the propagation of glanders by means of public horse-troughs, and we referred to the suggestion that by maintaining a constant flow of water this possibility would be reduced to a minimum. More lately mention has been made in the public press of the necessity of cleansing the interior of drinking fountains in case the common supply-pipes or cisterns within them should in course of time become unwholesome. The danger in this case, however, exists, we should say, rather in theory than in fact—that is to say, if the purity of the primary water supply can be relied on. Public fountains probably, without exception, are supplied from the main water supply. They are consequently not exposed to those unhealthy influences contained in sewer air by which the water supply of private dwellings is so often polluted. Certainly nothing but good could result from regularly cleansing the interior of any such fountain. Traces of earthy deposit would thus be removed, and assurance against contagion made doubly sure. If in any district the main water supply did happen to become impure, as in the case of cholera epidemics, such measures of purification would be absolutely necessary.

A LIBERAL PHYSICIAN AND THE JUBILEE.

THERE is still room for more device in the way of liberality in the Jubilee year, not for mere purposes of charity, but with a view of stimulating science and research and accomplishment of all kinds. We are happy to record a most creditable example in the case of a member of our own profession, who, though since graduation in Edinburgh he has become a dignitary of the Brazilian Empire, where he has been long resident, has not forgotten his native land and his *alma mater*, with all their great claims on the affection of their prosperous children. The *Aberdeen Herald* enumerates as follows the munificent gifts of Dr. Robert Halliday Gunning, who graduated in Edinburgh in 1816, writing a thesis on the "Nature and Treatment of Pulmonary Consumption." Happy the nation and the university that so treat their sons as to keep alive in them, forty years after, sentiments of refined patriotism and affection, to which such gifts testify:—

"1. To the Council of the Royal Society of Edinburgh—a triennial prize of £105, to be named 'The Victoria Jubilee Prize for the Advancement of Science.' 2. To the Council of the Society of Antiquaries of Scotland—£40 yearly, or £120 every three years, as they may prefer, to be named 'The Victoria Jubilee Gift,' the object of the founder being to assist experts to travel, with the view of 'examining other collections, and keeping the Edinburgh Museum as completely furnished with information and examples as possible.' 3. To the Senatus of the University of Edinburgh—£200 per annum, to provide eleven post-graduation triennial prizes of £50 each. These are to be named the Monro, Sir Charles Bell, Edward Forbes, Hutton Balfour, Joseph Black, Christison, Lister, Gregory, John Thomson, Simpson, and Alison prizes, and are to be administered by the Senatus—the incumbent of the chair in connexion with which the prize is to be awarded having a wide choice in the subjects of examination. 4. To the Royal College of Physicians of Edinburgh—£100 triennially, for a prize to bear the title 'Dr. Gunning's Cullen Prize for the greatest benefit done to Practical Medicine.' 5. To the Royal College of Surgeons of Edinburgh—£120 triennially, for a prize to be called 'The Liston Victoria Jubilee Prize,' which shall be open to all Fellows and Licentiates of the College, and shall be awarded for the greatest benefit done to Practical Surgery. 6. To the Edinburgh Association for the University Education of Women—£40 annually, for a bursary to be called 'The Victoria Jubilee Bursary.' In addition to the above, Dr. Gunning has intimated, through Lord M'Laren, a gift of £100 for the Ben Nevis Observatory. There are also gifts of £50 to each of four home mission stations in Edinburgh."

CHOLERA IN SOUTHERN ITALY.

UP to July 15th the amount of cholera in Southern Italy and Sicily was not very large, apprehensions of an extension of the disease having led to some exaggeration as to the extent of the mishief. But since then a decided increase has taken place, especially at Catania, where fifteen deaths occurred on the 16th, and where some twelve to fifteen deaths have occurred daily since then. The Angelo Custode and San Berillo quarters of the town present the conditions most favourable to further diffusion of the infection, they being in a terribly dirty state. Several cases of cholera have also occurred in Francofronte and Paterno, in the province of Catania, and five cases are reported from Grotte, in the province of Caltanisetta. Up to the 20th instant no fresh news had been received as to the outbreak in Calabria, on the main land.

MEDICAL MEN AND PHARMACISTS.

THE Belgian Medical Federation having received a complaint from the Pharmaceutical Association with reference to some animadversions made at a previous session on a number of pharmacists who had, as was averred, trenched unduly upon the province of medical men by doing a prescribing business, a somewhat warm discussion took place, which made it plain that, though the federation had no wish as a body to prefer a formal complaint against the pharmacists, still they as individuals felt disposed to agree with the sentiments which had given umbrage. It was remarked that, if the pharmacists had complained of any doctors infringing their prerogative by openly or in an unauthorised manner selling drugs, the federation, so far from seeking to defend their erring *confrères*, would have heartily joined in censuring them, and so the Pharmaceutical Association might fairly have been expected to disavow all attempts on the part of its members to take upon themselves the office of prescribing. A lame sort of defence seems to have been attempted for the pharmacists on the plea that they are quite as competent to prescribe as doctors are to dispense; but that kind of argument did not receive much attention, the meeting unanimously resolving to pass on to its other business without replying to the complaint. The members whose speeches had given offence stated that they considered themselves solely responsible, and that therefore they should in their individual capacities reply to the pharmacists.

PHYSICS AND PHYSIOLOGY.

THE Physico-Technical Reichsinstitut, recently established in Berlin, will open for regular work on April 1st, 1888, and every guarantee is forthcoming for its completeness and efficiency. The curatorium in connexion with it will offer peculiar advantages to students of the higher physiology, for whom it will suffice to mention that its president is Professor H. von Helmholtz, of the Privy Council. Besides this pioneer in physiological research, there will be attached to the curatorium Dr. Werner Siemens, who bears an honoured name in physics, and whose donation has put the establishment on a working basis; while Professor Förster, Director of the Berlin Astronomical Observatory, with other distinguished *savants* and investigators, will also contribute to its scientific attractions. The Physico-Technical Institute, it may be well to remind our readers, has not been devised for teaching purposes, but purely to facilitate research, in which the curators will be always at hand, as experts and consultants, to assist the investigator. It will be under Government protection and control, the authority ultimately responsible for its success being the Minister of the Interior.

CUTANEOUS OR ANATOMICAL TUBERCLES.

M. AUGUSTE POLLOSSON five years ago examined in the Lyons pathological laboratory four cutaneous or anatomical tubercles, one of which was from the back of his own hand, with the view of determining the truth of the views expressed by many writers, who look upon these anatomical tubercles as closely connected, to say the least of it, with tuberculosis. M. Pollosson, who gives a very minute description of the [illegible] (*La Province Médicale*, No. 28, 1887), failed, however, to find any tubercle bacilli, and none of the subjects from whom they were excised have at any time shown any sign of tuberculous disease. His observations are in complete accordance with the short account of these growths by Cornil and Ranvier. Nevertheless, he does not think these are anatomical tubercles which are [illegible] tuberculosis. He only affirms that the connexion is not invariable.

THE SUPPLEMENTAL CHARTER OF THE ROYAL COLLEGE OF SURGEONS.

WE learn that the petition presented to Her Majesty in Council praying for a Supplemental Charter for the Royal College of Surgeons of England (an abstract of which we published in our issue of June 4th, page 1151) will be considered by a committee of the Privy Council on Sept. 1st next. The Associations of Fellows and of Members should take care that vacation arrangements do not render them oblivious of their claims to be heard on a subject in which they are so deeply and so justly interested.

SIR MICHAEL HICKS BEACH.

IT will have been seen with much pleasure from Sir Michael Hicks Beach's letter to his constituents that he has derived great benefit from his sojourn abroad, and that there is a change for the better in his sight. The cataracts have not increased in density, and a slight defect in the retina and choroid of the right eye, which was recognised by Mr. Critchett before Sir Michael left England, has also undergone improvement.

HOSPITALS FOR INFECTIOUS DISEASE.

THE Local Government Board have consented to recognise the certificate of every medical practitioner as sufficient evidence of the nature of a case to warrant the removal of the patient to the hospitals of the Metropolitan Asylums Board, and have issued an order for this purpose. It is presumed that an order of a relieving officer is to be obtained before the removal of the patient, but in practice this method is generally abandoned, and a telegram to the manager's offices in Norfolk-street is sufficient for the purpose. So far as small-pox is concerned, there is little demand for the accommodation of persons suffering from this disease, for on Saturday there was not a single small-pox patient under treatment in the several hospitals of the Board.

PERSISTENT YAWNING AND SNEEZING AFTER REMOVAL OF A TOOTH.

A CASE of a somewhat remarkable character is at the present time in the London Temperance Hospital, under the care of Dr. R. J. Lee. A girl, fifteen years of age, had the last molar tooth in the lower jaw on the right side removed about six weeks ago. No anæsthetic was administered. She was in perfect health at the time. Half an hour after the operation she began to yawn, and has continued to do so constantly since. One yawn succeeds another without interruption, and with an interval of two or three seconds. Galvanism had been tried without effect, and other remedies previous to admission into the hospital. Three days afterwards the yawning changed to sneezing, and recently she has suffered from constant and rapidly succeeding fits of sneezing, each of which paroxysms appears to begin with a yawn. She seems to have no power of controlling herself, or only to a very slight extent; and if she attempts to do so, the next sneeze is more violent.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Georg Wiesner, Senior Medical Officer of the Hospital of the Holy Ghost, Frankfort-on-the-Maine, and Sanitary Councillor.—Dr. Grewingk, Professor of Mineralogy in Dorpat.—Dr. Alexander Reumont, Sanitary Privy Councillor of Aix-la-Chapelle, at the age of sixty-nine.—Dr. Kempen, Knight of the Order of Leopold, a distinguished Belgian Military Surgeon.

Digitized by Google

KING'S COLLEGE.

MR. EDGAR CROOKSHANK, M.B., has been elected Professor of Bacteriology, and the plans for a new bacteriological laboratory, to be built during the vacation, have been decided on. Mr. J. W. Groves has been elected Professor of Botany in succession to Professor Bentley, F.L.S., who has resigned the chair. Professor Groves will conduct a practical class in Vegetable Biology.

PROFESSIONAL CONFIDENCE.

A BELGIAN medical man has been condemned by the Court of First Instance, the Court of Appeal, and the Court of Cassation for refusing to give up the name of the mother of a child whose birth he announced. The Minister of Justice stated, however, in the House that there was no law to compel medical men to violate professional secrecy. The case is felt to be a hard one, and the Belgian Medical Federation are about to take the matter up by seeking counsel's advice.

SANITATION IN SHEFFIELD.

SPECIAL care is being given to the flushing of the sewers in Sheffield during this hot and dry weather. Under Dr. Sinclair White's supervision ordinary water-barrels holding some 250 gallons are pierced with an opening about eight inches in diameter, and round this is fastened a species of leather bag, the open end of which is fitted into the manhole of the sewer. By the turn of a lever the whole contents of the barrel are suddenly let off into the sewer, and in this way an effective flush is provided in a simple and inexpensive manner.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Professor Salkowski, who has charge of the chemical laboratory in the Pathological Institute, is to be offered the newly established Professorship of Medical Chemistry. Professor Ewaldis will be offered the Directorship of the new hospital at Urban.

Brussels.—In the recent second Doctorate Examination twenty-four candidates presented themselves, of whom four only were rejected, all the remainder excepting two passing with honours. This being one of the earlier examinations from which English practitioners who seek Brussels degrees are exempt, there are no successes to chronicle for such. We may mention, however, amongst the successful candidates for the Final Examination the name of Shapoorji Aspaniarjee Kapadia, L.R.C.P., L.R.C.S. Edin., lecturer on Hindustani at University College.

Cracow.—The Professorship of Surgery has been given to Dr. Ludwig Rydygier of Culm, author of a treatise on Surgery in the Polish language, and formerly *privat docent* in Jena.

Dorpat.—The professors of this university, the only one in Russia in which instruction is given through the medium of the German language, were recently directed to prepare to change the language of their lectures to Russian, but they objected so strongly to the change that they all sent in their resignations. This step seems to have produced some effect on the minds of the authorities, for they have announced that the Russification of the University will be deferred for three years. German professors who receive an invitation to Dorpat will have to be careful lest they find themselves shortly after their appointment ordered to lecture in a language with which they are more or less unfamiliar.

Ghent.—A statue of the late M. J. Guislain, the eminent alienist and professor, has been unveiled with an imposing ceremonial, in which M. Henri Lentz, who was deputed to attend on behalf of the Minister of Justice, made an eloquent speech. The medical profession were represented by M. le Professor Lefèbvre, President of the Royal Belgian Academy of Medicine, and M. le Professor Boddaert of Ghent.

Gratz.—Dr. Zuckerkandl, Professor of Anatomy, has been appointed Dean of the Medical Faculty.

Leipsig.—Professor W. Pfeffer of Tübingen has been invited to take the chair of Botany.

Paris.—The *concours* for three posts as *médecin des hôpitaux* has terminated by the nomination of MM. Josias, Juhel-Rénoy, and Hippolyte-Martin. MM. Dujardin-Beaumetz and Sappey have received the decoration of Commander of the Legion of Honour.

Prague (German University).—Dr. Knoll, Professor of Experimental Pathology, has been appointed Dean of the Medical Faculty.

Rome.—Dr. Pasquali has been appointed Ordinary Professor of Midwifery.

ON the 18th inst. the death occurred, at his residence in Cardiff, of Mr. F. W. Granger. On the 14th inst. the deceased was knocked down by an omnibus, and although the injuries received did not at the time of the accident appear serious, the unfortunate gentleman gradually became worse, and the illness, as above stated, terminated fatally. Mr. Granger, who was in his fifty-seventh year, was medical officer for the Cardiff Rural Sanitary Authority, a post he had held since 1872.

DR. SCHNEIDER (*Ministerialrath*) has resigned the post of President of the International Congress of Hygiene at Vienna. As his successor, the Bureau of the Organising Committee have unanimously elected Professor E. Ludwig.

PROFESSOR VIRCHOW, who takes a prominent part in the International Congress of Hygiene at Vienna, will at the close of its sittings start with Dr. Schliemann, the archæologist, for Egypt, on a "working-holiday" tour.

M. PASTEUR having consented to become a candidate for the office of Perpetual Secretary of the Paris Academy of Sciences, the other candidates have withdrawn their applications.

IN the recent matriculation examination at the University of London, 141 candidates passed in the honours division, 522 in the first division, and 94 in the second division.

DR. S. WEST will deliver the Bradshawe Lecture at the Royal College of Physicians on August 18th. The subject will be "Pneumothorax."

MR. CHARLES STONHAM and Mr. W. G. SPENCER have been appointed Assistant Surgeons to Westminster Hospital.

GREAT NORTHERN CENTRAL HOSPITAL.—The annual general meeting of the governors of and subscribers to this institution was held on the 15th inst. The report presented by the Committee of Management stated that the number of patients who obtained relief during the twelve months ended June last was 10,326, being an increase of 1260 over the previous year; of these 326 were in-patients and 10,000 out-patients, the attendances of the latter numbering 32,770. No less than 2570 cases of accident were treated during the same period. The ordinary income of the year amounted to £3481, which was less by £160 than that of the previous year, and the expenditure to £3508, which was £512 less than that of the preceding twelve months. The surplus of the Hornsey Children's Jubilee Fund, amounting to about fifty-five guineas, is to be paid to the building account of the hospital.

ABSTRACT OF

STATISTICS OF THE MONTREAL MATERNITY HOSPITAL.

COMPILED BY W. A. DE WOLF SMITH, M.D. &c.,
PHYSICIAN TO THE MONTREAL DISPENSARY.

THE following is a collection of statistics gathered from the register of the Montreal Maternity Hospital, a small building situated in a very unfavourable part of the city, and possessing very inferior accommodation for the patients, the attendants, and the students who learn the practical part of midwifery at it.

Some years ago the hospital admitted about 130 patients a year, but lately, owing to the fact that the Western Women's Hospital has come into competition with it, the number has fallen to an annual average of less than 100. There is a list of patients' names entered in the register from 1844, but no particulars are given with any of the cases until 1851, and these observations are brought up to the end of 1883—a period of thirty-three years. During this time 3483 patients were admitted, an average of 106 a year. The number of children born in the institution was 3520, there having been thirty-five cases of twins and one case of triplets. The time spent in hospital is not of much importance, but it may be noted that the shortest time spent there was one day—four patients having been in for that length of time only. The longest stay in hospital was 213 days, while the average number of days spent by each patient was twenty-seven. The time of the year does not seem to have had much influence on the births. The largest number of children were born in April, and the other months follow in this order—May, June, October, July, January, November, February, December, March, August, and September, the numbers declining very evenly, however. This differs from Dr. Sutton of Kentucky, as quoted by Dr. Carpenter, who gives the greatest number of births in December and the fewest in January. Dividing the year into quarters, the largest number of births, 973, occurred in the second quarter, 844 in the fourth quarter, 825 in the first quarter, and the smallest number, 815, in the third quarter. This arrangement may be due to the smallness of the numbers considered, as Dr. E. M. Snow, in his report for 1885 to the City of Providence, gives statistics for thirty years, in which the largest number of births, 8459, occur in the fourth quarter, 8149 in the second quarter, 8065 in the third quarter, and 7929 in the first quarter.

The ages of the patients admitted show the greatest range, running all the way from thirteen to forty-eight. Three patients were admitted at thirteen years of age, and two at fourteen. Dr. MacCallum quotes one of the former in his report of the institution, published in 1879. She was, to quote from the report, "a private patient, and when admitted was in short dresses. Although she was short in stature, her hips were wide and her chest well developed. Some days before labour set in an examination of the pelvis was made with Dr. Lumley Earle's pelvimeter. The bulbed extremities could be separated at the brim to the extent of three inches and a half without causing pain, and we therefore concluded that no obstruction would be offered to the passage of the head from narrowing of the conjugate. . . . Her labour was natural, of ten hours' duration, and she gave birth to a male child weighing 7 lb. 1 oz. She was confined on Sept. 13th, 1869, and her fourteenth birthday was in the following month of December." There were fifteen patients admitted over forty years of age, the two oldest being forty-six and forty-eight years of age respectively. The greatest number of patients were admitted at twenty-two years of age, while those at twenty and twenty-four come next. The average age of all patients admitted was twenty-five. The majority of the patients have been primiparæ, though previous to 1869 the majority were multiparæ, a circumstance which, I think, may be explained by the fact that while the Imperial troops were stationed here the hospital was full, many of the men were confined in the hospital.

The majority of the labours have been natural, over [illegible] been of that description. A number which [illegible] have been protracted have, I am sure, been [illegible] by the administration of chloral, now [illegible] Hospital, alone or in connexion with hot-water douches in cases of rigidity of the parts. In over 90 per cent. of the cases—3404 out of 3558—the head presented. Breech presentations occurred in ninety-eight, footling thirty, and knee three times; the frequency of breech presentations being one in 36·3 cases, this being more frequent than is given by Churchill, and a little more frequent than according to Ramsbotham. Footling presentations occurred once in 118·6 cases, and knee presentations once in 1186 cases, this being nearly three times the frequency given by Madame Lachapelle. Placenta prævia occurred in three cases, and the face presented in eight. The age of the patient does not seem to have had much influence on the duration of labour, nor does the fact of the mother being a primipara or multipara. The duration of labour was as follows:—

Under 1 hour	...	...	...	...	...	71	cases.
From 1 to 4 hours	...	...	...	...	...	672	"
" 4 to 8 "	...	...	...	...	...	921	"
" 8 to 12 "	...	...	...	...	...	654	"
" 12 to 16 "	...	...	...	...	...	472	"
" 16 to 20 "	...	...	...	...	...	172	"
" 20 to 24 "	...	...	...	...	...	96	"
" 24 to 48 "	...	...	...	...	...	249	"
" 48 to 72 "	...	...	...	...	...	35	"
" 72 to 120 "	...	...	...	...	...	10	"

One case lasted seven and another ten days. Thus it is seen that by far the largest number of deliveries were terminated inside of twelve hours. The average duration of labour in 3359 cases was ten hours and twenty minutes, being slightly over the average given by Dr. MacCallum in his report. The average time before delivery at which the membranes ruptured was three hours and a half. In one case they ruptured 120 hours, and in three cases they ruptured ninety-six hours, before delivery; while in 250 cases they ruptured at the moment of delivery. The sex of the child is given in 3477 cases. Of these, 1788 were males, 1689 females—a proportion of 105·85 males to 100 females—this being about the general proportion as regards legitimate children, but somewhat higher than common amongst illegitimate children, which, of course, most of these were.

While there is a predominance in the number of male children born, they also, as an average, are larger in size and weight than female children. The average length of all children born in the hospital was 19·75 in., or, excluding premature births, 19·88 in. The average weight of all children born in the hospital was 7 lb. 10⅜ oz., or, excluding premature births as before, 7 lb. 12⅛ oz. Three children were born measuring 30 in. in length, and five measured 28 in. There were two children (twins) born alive weighing 2⅜ lb. each, but they soon died. Thirteen weighed between 11 lb. and 12 lb., and one each 13 lb., 16 lb., and 16⅜ lb. respectively. The average weight of male children was 7 lb. 12¼ oz., the heaviest weighing 13 lb. The average length of male children was 20⅛ in., the longest being 30 in. Female children averaged 7 lb. 6¾ oz. in weight, although the largest female child weighed 16⅜ lb., or more than any male. Their average length was 19 1/3 in., the longest being 28 in. Of 3405 placentæ noted the average weight was 24¼ oz. There were two with children at full term which weighed only 6 oz. each. Eight weighed 8 oz., 387 weighed 16 oz., or less, 2612 weighed between 1 lb. and 2 lb., 360 between 2 lb. and 3 lb., and there were with single children placentæ weighing 50, 51, 52, 53, 55, 56, 58, 60, 64, and 65 ounces respectively. In cases of twins there were two placentæ weighing over 4 lb., and in the one case of triplets recorded the placenta weighed 6½ lb. The shortest umbilical cord measured 4½ in., and the longest 56 in. There were twenty-nine 10 in. and under in length, and twenty-six 40 in. and over, the largest number being 20 in. long, and the general average being 22½ in.

The duration of pregnancy is a very interesting question, but, unfortunately, these cases are not recorded with sufficient exactness to allow of any calculations being based upon them. Deducting, however, those cases given as premature, and cases in which menstruation continued for some time during pregnancy, we have an average of 294 days as the duration of gestation. The shortest period of gestation is given as 173 days, or a trifle over five months. The greatest number were delivered at 280 days, while there are forty-two cases given in which pregnancy lasted 300 days or more, three of these being at 361, 368, and 385 days respectively—my own opinion being that these are cases of error. Excluding also these cases, then, which seem hardly

Digitized by Google

possible, we have an average of 293 days as the duration of gestation. The largest number of cases were, of course, primiparæ—viz., over 61 per cent. There were, however, a number of multiparæ, one case being a tenth pregnancy, four cases being eleventh, and two cases twelfth pregnancies.

Of the 3520 children born in the hospital, 150 were dead, a proportion of one in 23·5 nearly, the proportion of dead children born in the St. Louis (Mo.) Female Hospital being at the rate of one in 12·16, according to the report for 1884-85, and in Burlington (Vt.), according to Dr. J. H. Linsley, the proportion in 1885 was one in 19·55. Of 3483 women admitted thirty-five, or a small fraction over 1 per cent., died, a rate of one in 99·5, this being an increase over the number given by Dr. MacCallum, but less than the rate given in the report of the St. Louis Hospital, where it was 1½ per cent. Of these deaths, eight were from puerperal fever, which broke out in the hospital in 1871 and 1872, in both instances, however, being brought into the hospital from the city, where it had been prevailing for some months previously. Owing to the small accommodation of the hospital, it was closed for a time on both these occasions. Four deaths occurred from uræmic poisoning and one each from thrombus of the labia, congestion of the lungs, heart disease, post-partum convulsions, peritonitis, and Bright's disease. In seventeen cases the cause of death is not given.

Of the 150 children born dead, ninety-two were males and fifty-eight females, or in the proportion of 158·6 males to 100 females. The average weight of these children was—

	Males.	Females.
Maximum	11 lb.	9 lb.
Mean	5¾ lb.	5½ lb.
Minimum	3 oz.	1⅝ lb.

Dead children were distributed as follows, according to pregnancy:—

	1st.	2nd.	3rd.	4th.	5th.	6th.	7th.	8th.	9th.	Total.
Males	54	23	7	3	2	1	1	1	0	92
Females	30	15	4	2	1	2	1	1	2	58
Total	84	38	11	5	3	3	2	2	2	150

The average weight of children born dead, according to pregnancy, was as follows:—

	lb. oz.		lb. oz.
1st pregnancies	6 3	6th pregnancies	4 14
2nd ,,	6 2	7th ,,	6 8
3rd ,,	5 0	8th ,,	6 14
4th ,,	6 15	9th ,,	8 14
5th ,,	7 5		

Eighty-seven cases are given as being premature births, and of these fifty were males and thirty-seven females. Fifty-five of the mothers were primiparæ and twenty-one were in their second pregnancy. The average weight of the placenta in these cases was 14⅓ oz. The average weight of all children born prematurely was 3 lb. 5 oz., and the average length was the same in both sexes within a small fraction of an inch—viz., 14¾ in. Twins occurred thirty-five times, or a proportion of one in ninety-four cases, nearly. In these cases the average duration of labour was 9 hours 50 min., the extremes being 20 min. and 103 hours. The placentæ belonging to these children averaged 34⅓ oz. in weight, and the umbilical cords averaged 21 in. in length. The average duration of pregnancy in cases of twins was 277 days. Of the seventy children born sixty-one were alive, seven dead, and two stillborn. Seventeen of the mothers were confined for the first time, eleven for the second, and five for the third time, while one case was a fifth, and one an eighth, pregnancy. The average weight of twins was:—

	lb. oz.		lb. oz.
Of two males	6 8	Of all children	6 3
,, two females	6 6	,, males	6 4
,, male and female	5 13	,, females	6 2

Only one case of triplets is recorded. This was an Irish woman, about thirty-three years of age, and married. It was her third pregnancy, and gestation had lasted 280 days. Forceps were used to deliver one of the children, the others being born naturally. The breech of one presented, and the heads of the other two. The duration of labour was three hours. Two of the children were males, and one female; they measured nineteen, sixteen, and sixteen inches, and weighed 5½ lb., 4¾ lb., and 4¾ lb. respectively. The placenta, as previously mentioned, weighed 6½ lb., and the cords measured fourteen, twelve, and twelve inches. Two of the children were alive, and one was stillborn.

Although no opportunity has existed for the comparison in this hospital, it may be interesting to note the comparative frequency of plurality births among the white and coloured population. In thirty-one years the proportion is as follows:—

Colour.	No. of births.	Plurality births.	Proportion.
White ...	63721	715	1 in 89·12
Coloured ...	2490	53*	1 in 45·1
Total ...	66211	768	1 in 86·21

* All cases of twins.

The above table shows a much larger proportion of plurality births amongst the coloured than amongst the white population.

In the hospital instrumental interference was required in seventy-eight cases, forceps in seventy-five cases, the perforator twice, and the blunt hook once. The forceps were applied once in 46·5 cases, sixty-six cases were primiparæ, and in these the difficulty may be attributed to rigidity of the soft parts, deformity of the pelvis, or to malposition of the head, or to any of these causes acting in combination. The cases of deformity of the pelvis are very few, and this may doubtless be attributed to the fact that the hygienic surroundings of the working classes are better in Canada than in older countries, and also to the fact that girls are not put to work at as tender an age as in some countries. In none of these cases is it recorded that the mothers died, while of the seventy-five children delivered with forceps thirteen, or 17·33 per cent., died. In three cases the forceps were applied to hasten the delivery in cases of convulsions, once in a case where symptoms of exhaustion appeared, and once in a case of narrowing of the conjugate diameter of the brim, with prolapse of the funis. The forceps generally employed are Rigby's and Simpson's, but on one occasion Tarnier's forceps *à aiguille* were used. The average age of these patients was twenty-six, and the average duration of the labours a little over twenty-four hours. Of the children forty-five were males and thirty females. The average length of these children was twenty-one inches for the males and twenty inches for the females, and the average weights were 8 lb. 5 oz. and 7 lb. 12 oz. respectively. The perforator was used twice to diminish the size of the fœtal head. The first case was a girl aged nineteen, in her first confinement. The breech presented, and the case had lasted forty-three hours when, after perforation, she was delivered of a male child, measuring 18 in. in length and weighing 7⅝ lb. The second case was a girl admitted in labour with her second child. The shoulder presented, and the funis protruded from the vulva. Great difficulty was experienced in turning, and after it was accomplished the head had to be perforated behind the ear, when, after a gush of water, the collapsed head was expelled. A full description of the case is to be found in Dr. MacCallum's report, published in vol. xx. of the Transactions of the Obstetrical Society of London. Version was performed in six cases. In all of these the mothers recovered, but in only one instance was the child born alive; in one other case, although stillborn, it was resuscitated.

Hæmorrhage after delivery is of rare occurrence in this hospital, and this is no doubt greatly due to the care with which the uterus is attended to during the expulsion of the child and removal of the placenta, and also to the care with which adherent membranes are treated. The rules laid down for the guidance of students at this hospital are given by Dr. MacCallum in his report, and are very complete. When hæmorrhage does occur after delivery, the treatment consists in strong grasping pressure on the fundus uteri; the application of cold, either externally or through the vagina; and the introduction of the hand into the uterus. Ergot of rye has also been given.

Ten cases were followed by convulsions. In three it is recorded that the urine was albuminous, and in one it is stated that the urine was free from albumen, while the condition of the urine in the other cases is not given. In two cases blood was drawn from the arm in connexion with inhalations of chloroform and the use of chloral and bromide of potassium, which were also used in the other cases. Bleeding was not refrained from because of any belief in its inefficiency, but because the class of patients coming to hospital will not, as a rule, bear it. In three of the cases the forceps are mentioned as having been used to complete the delivery. The average duration of labour in these cases was fourteen hours. Six of the children were males, and averaged 8⅝ lb. each; four were females, and averaged 8⅛ lb. each. Of the ten children, two males and one female were dead.

Digitized by Google

Three cases of insanity after delivery are reported—all in primiparæ. The first was the subject of fibroid tumour of the uterus and metrorrhagia, and was an habitual opium eater, although this habit was partly overcome while she was in the hospital. On the third day after delivery she was attacked with acute mania, and became very violent. Under treatment she rapidly improved, and left the hospital on the twelfth day after delivery. The second was a young girl who had been seduced. Five days after a natural labour she was attacked with mania. She improved under treatment, but finally had to be sent to the asylum for the insane. In this case there was a family history of insanity. The third was a girl aged twenty-one, whose labour was natural. She was attacked with insanity six days after delivery, after having received a severe mental shock. She was very violent and abusive, and had homicidal tendencies. In three weeks, however, she recovered sufficiently to leave for home, and had no return of the attacks. The treatment of these cases consisted in full doses of chloral and bromide of potassium, with warm purgatives and nourishing diet.

Among the more curious things met with in the hospital were:—Three anencephalic children, two with supernumerary fingers, one with two teeth, and one covered with hair. Two were born with clubbed feet, and one with a bifurcated cord; one child was born with a spina bifida situated over the sacral region. It was removed to the Montreal General Hospital, and the tumour tapped by Dr. Roddick. The child lived only a few days, however. One blighted fœtus was born with a healthy, well-formed child. It measured 6 in. in length. Two patients were married while in the hospital. One patient was admitted who presented many of the signs of advanced gestation, but on examining her closely it was found to be a case of phantom pregnancy. Three patients menstruated for the first seven months of their pregnancy, and two for the first three months.

KAKKÉ, OR JAPANESE BERI-BERI.

No. I.

KAKKÉ, a complaint now regarded as identical with the beri-beri of India, has long ravaged the great commercial centres of Japan, but it is only in recent years that it has been brought within the range of scientific observation. The first complete accounts of the symptomatology were those given by foreigners resident in the country; but during the last five years the work of research has been prosecuted under more advantageous conditions by highly educated Japanese medical practitioners of the Western school, and one of these, Surgeon-General Takaki, a Fellow of the English College of Surgeons, and a former house-surgeon to St. Thomas's Hospital, has now published in the *Sei-I-Kwai Medical Journal* some original observations that will constitute a great landmark in the study of the disease, and a contribution of no small importance to physiology. Mr. Takaki, having formed a strong opinion that the relative deficiency of nitrogenous elements in the ordinary dietary of his countrymen, as compared with the European standard, might account for the great prevalence of kakké in the naval forces, succeeded in obtaining permission from the Japanese Admiralty in 1883 to make a number of experiments in the service upon a scale of great magnitude. The substance of his creed and the nature of the evidence he gathered to support it by the end of a single year may be collected from the subjoined extracts from his contribution to the *Sei-I-Kwai Medical Journal* in April, 1885:—

"1. The elements which enter into the formation of the animal tissues, and whose waste must, I believe, bear a definite relative proportion with the food, and therefore, to make up the loss of keeping the tissues in a perfect condition, must be accordingly supplied. For example, the relative proportion of nitrogen and carbon is one to fifteen. An adult man doing very heavy work must have a supply of twenty-three grains of nitrogen at least to every kuwamme (10,042 drachms) of the weight of the body: thus 345 grains is required by a man weighing fifteen kuwamme (15,630 drachms), while the quantity of carbon is fifteen times as much in the course of twenty-four hours. I found by very careful investigations that the food taken by the men attacked by kakké was greatly deficient in nitrogen and contained a great excess of carbon, their relative proportion being one to twenty-eight or more.

"2. The *Riujio*, a training-ship bearing 276 men, including officers, had sailed first from Shinagawa (Yedo Bay) to Wellington, New Zealand; thence to Valparaiso, Chili; from Valparaiso to Calao, Peru; then from the latter port to Honolulu, Sandwich Islands; and thence to Shinagawa, having spent 272 days in making the whole trip. During the voyage 169 cases of kakké occurred, 160 out of which appeared among the sailors and petty officers, with twenty-five deaths before she had arrived at Honolulu. The fact was indeed alarming, and consequently a careful examination was subsequently made by a special committee appointed by the Minister of Marine, and what they have found in regard to the relative proportion of nitrogen and carbon, and their respective quantity, is stated below.

Before the arrival at Honolulu.

Rank.	Daily quantity of nitrogen.	Daily quantity of carbon.	Relative proportion.
Sailors	189 grains	5497 grains	1 to 28
Cadets	241 ,, ...	6331 ,, ...	1 to 25
Warrant officers	280 ,, ...	5902 ,, ...	1 to 20
Officers	359 ,, ...	7578 ,, ...	1 to 20

After the arrival at Honolulu.

Rank.	Daily quantity of nitrogen.	Daily quantity of carbon.	Relative proportion.
Sailors	286 grains	4881 grains	1 to 16
Cadets	325 ,, ...	4772 ,, ...	1 to 11
Warrant officers	365 ,, ...	4707 ,, ...	1 to 11
Officers	437 ,, ...	5901 ,, ...	1 to 11

"The careful examination following the course of the voyage, in regard to the appearance and disappearance of the disease, shows that whenever the quantity of nitrogenous substances was diminished and carbohydrates increased in quantity, it always appeared, but, on the contrary, whenever the reverse was the case, the disease retrogressed or disappeared entirely.

"3. The *Tsukuba*, a training ship, was then sent out to follow the same course as that the *Riujio* had taken, with a supply of the food elements, the relative proportion of nitrogen and carbon of which was one to fifteen. But these two elements were actually taken by the men in the proportion of one to seventeen, the total quantity of nitrogen being 450 grains, and of carbon 7650 grains daily on the average. In the course of the 287 days of the voyage, four cadets and ten men were attacked by the disease, and it appears that these cadets were unable to take condensed milk, while their fellow-cadets had taken one pound of it weekly; also eight out of the ten men had been unable to eat meat as the others did, so that there was a distinct history of the quantity of nourishments having been much less with those affected than with those not affected. There was not a death from disease during the whole voyage.

"4. The relative proportion of nitrogen and carbon in the navy rations in 1883 was one to twenty-eight, showing that there was a great deficiency of nitrogen and great excess of carbon. During 1884 some improvement has been made, resulting in a great increase of nitrogen (yet not reaching the necessary quantity), with a comparative increase of carbon. As, however, the increase of nitrogen was greater, the relative proportion of the two elements came down to one to twenty of nitrogen and carbon in the food."

Then follows a statistical table, demonstrating that a diminution in the relative proportion of carbon and an increase in that of nitrogen in the rations were followed by a decrease in the number of cases and deaths during the year 1884; other tables detailing the relative proportions of nitrogen and carbon in the principal articles of food; and, finally, a series of twelve diet scales. From the latter Mr. Takaki had selected the combinations he considered most suitable, and expressed his conviction that their adoption would ensure the prevention of the complaint.

The subject was continued in a further article in the same journal in April, 1886, and the writer there proffered some interesting figures in connexion with the naval prisoners,

Digitized by Google

from which we quote the following (with the correction of an arithmetical error occurring in the original):—

Year.	1. DISEASE.			2. DIET.		
	Number of prisoners.	Number of cases of kakké.	Percentage.	Nitrogen, in grains, daily.	Carbon, in grains daily.	Rates of N. & C.
1883	113	69	61·06	216	7054	1 to 32·65
1884	128	73	57·03	258	6614	1 to 25·06
1885	168	0	0·0	289	5839	1 to 20·20

The most significant statistics, however, are those published in the *Sei-I-Kwai Journal* for May of the present year, which carry the results to the end of 1886. Mr. Takaki there gives the following comparative table showing the number and proportion of cases of kakké for nine years, from 1878 to 1886 nclusive.

Comparative Table showing the Number and Proportion of Kakké Patients during nine years.

Year.	Force.	Patients.	Ratio of patients per 100 of force.	Admitted to hospital.	Ratio of admitted per 100 of patients.	Dead.	Ratio of dead per 100 of patients.	Invalided.	Ratio of invalided per 100 of patients.
1878	4528	1485	32·79	325	21·89	32	2·15	...*	...*
1879	5081	1978	38·92	485	24·51	57	2·88	8	0·40
1880	4956	1725	34·81	319	18·49	27	1·57	9	0·52
1881	4641	1163	25·06	300	25·79	30	2·58	16	1·38
1882	4769	1929	40·45	545	28·25	51	2·64	17	0·88
1883	5346	1236	23·12	378	30·59	49	3·96	4	0·32
1884	5638	718	12·74	209	29·10	8	1·11	1	0·14
1885	6918	41	0·59	25	60·97	—	—	1	2·44
1886	8475	3	0·04	—	—	—	—	—	—

* Uncertain.

From this we shall see that if the whole period be divided into two parts, the first including the six years from 1878 to 1883, the second the three years from 1884 to 1886, during which the new dietetic rules were in force, the percentage ratio of kakké cases to the naval force fell from 32·79 in the first term to 4·45 per cent. in the second; while the percentage mortality of the disease shows a reduction from 2·63 to 0·37, and in the last two years to zero.

A second table, which gives the diminution in the number of days during which kakké patients were under treatment, after the adoption of the new dietary, is equally telling,

Comparative Table showing the Number of Days of Treatment under Different Grades of Service during four years.

Year.	Duration of ordinary work under treatment.	Duration of light work under treatment.	Duration of rest.	Duration in hospital.	Total.
1883	25,235	7612	7894	22,534	66,275
1884	10,667	4675	5542	11,309	32,213
1885	154	69	175	1012	1410
1886	28	—	71	—	99

and will afford material for the financial authorities of the navy when they desire to strike a balance between the increase of outlay in food and the saving in hospital and other expenses connected with the treatment of the disease. Whatever be the result of such a calculation from the pecuniary point of view, there is no doubt of the immensity of the gain as judged by the standard of the political economist and the humanitarian. Nor is the interest of the question by any means confined to Japan or to students of the particular disease which has been taken as a measure of the results of the experiment. With regard to kakké, there is reason to believe that it still exists amongst the Chinese, who, indeed, were the first to describe its symptoms, and if we assume that the complaint is identical with beri-beri, the area of its ravages will be found to extend over the greater part of our Indian Empire, Ceylon, and even to certain regions of South America. It is, moreover, known that European residents in these places share the danger with the native population, as instanced but recently by the grave losses inflicted by beri-beri upon the Dutch troops in India, and hence, even if we are moved by no higher considerations than those of selfishness, it is desirable that we should give a share of our attention to the etiology and treatment of the disease.

HOSPITAL SUNDAY FUND.

THE following are the principal contributions to the Hospital Sunday Fund, which have been lately received at the Mansion House:—All Hallows the Great and Less (with additions), £55; St. Pancras Parish Church, £50; Newcourt Congregational Chapel, Tollington-park, £51; St. Matthew's, Bayswater, £200; St, Nicholas', Chislehurst (including a further £100 from Richard Foster, Esq.), £217; Spanish and Portuguese Synagogue, £50; the Great Synagogue, £247; Bayswater Synagogue, £96; New West-end Synagogue, £68; and Central Synagogue. £63.

The fund at the time of our going to press amounts to nearly £39,000.

A meeting of the Council of the Fund is to be held at the Mansion House at 4 P.M. on the 25th inst., to order the payment of awards to hospitals and dispensaries, as recommended by the Committee of Distribution.

WILLS OF MEDICAL MEN.

THE will of Mr. William Chapman Begley, M.R.C.S. and F.R.C.P. Lond., late of 26, St. Peter's-square, Hammersmith, who died on April 12th last, was proved on the 27th ult. by Mrs. Jane Begley, the widow, and Mr. Claudius Francis Du Pasquier, the executors, the value of the personal estate exceeding £6000. The testator bequeaths £4200 consols, with any additions he may have been able to make thereto, upon trust to pay the dividends to his wife for life, and then for the College of the Holy and Undivided Trinity in the University of Dublin for the establishment of four studentships in medicine in the said college, tenable for four years, to be held by members of the college who have passed through the greater part of the undergraduate course in arts, and shall not have commenced the study of medicine. The residue of his property he gives to his wife.

The will of Frederick John Hensley, M.D., late of 10, Coleherne-road, South Kensington, who died on April 4th last, was proved on the 19th ult. by Mr. Thomas William Hensley and Miss Emily Marianne Hensley, the son and daughter, two of the executors, the value of the personal estate exceeding £1600. The testator gives the goodwill of his medical practice, together with drugs and books, and a piece of freehold land at Finchley, to his son Philip Henry and £50 to his servant Sarah Brown. The residue of his property is to be divided between his nine children in various proportions.

The will of Mr. John Chatto, M.R.C.S., librarian to the Royal College of Surgeons of England, late of 3, Chapel-road, Notting-hill, who died on April 19th, was proved on the 18th ult. by Miss Jane Chatto, the sister and sole executrix, the value of the personal estate exceeding £3000. The testator gives all his property to his said sister.

The will of John Henry Cook, M.D., late of 44, Chepstow-place, Bayswater, who died on May 28th last, was proved on the 14th ult. by Mr. John Wickham Barnes, the sole executor, the value of the personal estate exceeding £600. The testator gives certain furniture to his housekeeper, Elisabeth Henderson, £100 to his executor, and legacies to relatives and others. He leaves upon trust for his nephew Richard Todd, £1000 Brazilian 5 per cent. bonds and £100 Costa Rica 4 per cent. bonds, and for his niece, Mrs. Martha Ward Jull, £2000 Brazilian 5 per cent bonds, for life, and on their deaths to their respective children. The residue of his property he leaves upon trust for his said nephew and niece and on their decease for their children, share and share alike.

Digitized by Google

The will of Mr. Charles James Bracey, M.B., F.R.C.S., late of 155, Hagley-road, Edgbaston, Birmingham, who died on April 21st last, was proved on the 1st ult. in the Birmingham district registry, by Mrs. Edith Jane Bracey, the widow and sole executrix, the value of the personal estate exceeding £5000. The testator gives all his property to his said wife absolutely.

The will of John Vaux, M.D., late of Chestergate, Macclesfield, who died on January 30th last, has been proved at the District Registry of Chester by Miss Mary Elizabeth Vaux and Miss Charlotte Marie Dyhrenfurth Vaux, the daughters and executors, the value of the personal estate amounting to upwards of £3000. The testator, after exercising the power of appointment given him under the will of his father, gives all his linen, plate, glass, pictures, household effects, surgical instruments, and books to his wife for life, and then to his daughters. The residue of his property he leaves upon trust to pay the interest (as also the capital, if his trustees shall think fit) to his wife for life; and at her death the ultimate residue is to be divided between his children in equal shares.

The will of William Murray, M.D., late of Burley, near Otley, Yorkshire, who died on April 13th last, has been proved at the Wakefield District Registry by Mrs. Sarah Anne Murray, the widow, Mr. James Murray, the brother, and Mr. Robert Fox, the executors, the value of the personal estate amounting to upwards of £3500. The testator gives all his household furniture and effects to his wife. The residue of his property he leaves upon trust to pay the income thereof to his wife for life or widowhood, and at her death or marriage for his children in certain proportions.

The will of Mr. John Hurd, late of Yatton, Somersetshire, surgeon, who died on April 10th last, was proved on the 4th ult. by Mrs. Matilda Hurd, the widow and sole executrix, the value of the personal estate exceeding £1000. The testator gives all his property to his wife absolutely.

The Scotch Confirmation, under the seal of the Commissariat of Fife, of the trust disposition and deed of settlement, of William Traill, M.D., late of Woodwick, granted to Mrs. Anna Harvey or Traill, the widow, David Thomson Glover, and Allan Briggs, the executors, was resealed in London on the 11th inst., the value of the personal estate exceeding £4000.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. Wm. Dollin Alexander, formerly of Summit House, Clapton, but late of Broomhill Bank, Tunbridge Wells, and 9, Second Avenue, Brighton, £100 each to the Stoke Newington Dispensary and the Tunbridge Wells Dispensary.—Mr. John Bacon, late of Liverpool and of Clwyd Hall, Llanychan, Denbighshire, £1000 each to the Liverpool Northern Hospital, the Liverpool Southern Hospital, Bootle Borough Hospital, Stanley Hospital, Kirkdale, near Liverpool, the Liverpool Royal Infirmary, and the Denbigh Infirmary; and £300 to the Convalescent Institution, Woolton.—Lieut.-Col. Wm. Henry [illegible], late of Andover, Southampton, £300 to the Winchester [illegible] Hospital.—Right Hon. Henry Baron Hindlip, late of [illegible] Hall, Worcester, and Alsop-en-le-dale, Derby, £1000 to the Burton-on-Trent Infirmary.—Mr. Abraham Flatau, formerly of Ropemaker-street, Finsbury, but late of 197, Maida-vale, £100 to such Charities as his executors may think fit.—Mr. Walter Samuel Tollet Sandilands, late of Fenchurch-avenue, and Highfield Grange, Sandown, Isle of Wight, £500 each to the London Hospital, East-end, the Royal Free Hospital, Gray's-inn-road, the Cancer Hospital, Brompton, and the Royal Hospital for Incurables, Putney-heath; and the ultimate residue of his property to such charitable institutions and in such parts as his wife shall appoint.—Miss Ivy Webster, late of Exeter, £2000 to the [illegible] and Exeter Hospital.—Miss Maria Beaumont, late of [illegible]-road, Stoke Newington, £1000 to Mrs. Pennefather to establish a bed in the hospital under her superintendence [illegible] Mildmay Conference Hall; £1000 for the benefit of [illegible] at Furnille-square, Bethnal-green; £1000 each [illegible] Hospital for the Paralysed and Epileptic, [illegible] Bloomsbury, and the Royal Hospital for [illegible], Putney; £500 to the Asylum for Invalids, Stoke [illegible]; and £200 to the Home for Confirmed Invalids, [illegible], Highbury.—Mrs. Charlotte Frances Brownley, [illegible], East End, Finchley, £250 to the Small-pox [illegible] Hospital, Highgate, and the University [illegible], and £50 to the Convalescent Home, [illegible]

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Oldham Urban District.—The report which Dr. James Niven has presented to the Corporation of Oldham on the health of the borough during 1886 is one of the most complete documents which we have received. Commencing with a geographical description of the district, and showing by means of a large plate what is the superficial geology, it next proceeds to discuss all the various matters influencing health in the borough, such as dampness and faulty construction of dwellings, smoke nuisances, trapping and ventilation of drains and sewers, building on "tips," and such-like subjects. We are glad to observe a strong condemnation of the practice of building back-to-back houses, the rooms in which are never adequately ventilated. It only needs a large aggregation of such dwellings in any district to bring about that special musty smell, so akin to that which prevails where typhus exists, which attaches to this class of dwelling. Open space about individual houses and the possibility of a through current of air are of the utmost importance, especially in our larger cities and towns. As regards work done in the borough, there is a satisfactory record. The Westhulme sanitary hospital was twice full, and, under the pressure of some typhus, the separation of diseases could not be properly carried out, scarlatinal patients being placed in the same ward as those suffering from typhoid. Some additional hospital provision will now be needed. A wave of scarlatina passed over the borough, and there was a by no means inconsiderable prevalence of typhoid fever. The statistical portion of the report is very exhaustive, the value and bearing of vital statistics being discussed at considerable length in their various aspects. The general death-rate during 1886 was 22·7 per 1000. In connexion with summer diarrhœa, Dr. Niven is of opinion that the disease ought to be grappled with, and he proposes to issue a sanitary guide for distribution at each house within the borough, to assist in diminishing mortality from this cause. And as regards more general action in the same direction, he advocates special flushing of sewers, the use of potent disinfectants in the midden pans, the ventilation of houses and the cooking and boiling of all infants' food as aids in preventing this fatality. Amongst the various appendices to the report are meteorological and other records, which if continued year by year will afford very valuable material for studying the causes of preventable disease amongst the population.

Kingston-on-Thames Urban District.—Estimating the population at 22,655, Dr. Shirtliff shows a death-rate of 19·3 per 1000 in 1886. The diphtheria death-rate is one of the most serious features of the district, for it has now for several years past been largely in excess of the rate prevailing in the country generally, and so long as the conditions of contamination by sewer air remain, the authority cannot even plead that they have done their utmost to prevent it. Again and again has this matter been pressed on the authority, the necessity for breaking the direct connexion between the rain-pipes and the sewers having been specially advocated. Such direct connexion turns these pipes into ventilators during dry warm weather, and their position endangers the health of the inmates of rooms in the upper storeys of houses. Other matters, such as the provision of a hospital and an abattoir, also call for action.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5796 births and 3660 deaths were registered during the week ending July 16th. The annual rate of mortality in these towns, which had been 17·6, 18·1, and 19·6 per 1000 in the preceding three weeks, further rose last week to 20·7. During the thirteen weeks of last quarter the death-rate in these towns averaged 19·8 per 1000, and was 1·4 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 13·6 in Portsmouth, 14·4 in Bolton, 14·7 in Nottingham, and 15·5 in Wolverhampton. The rates in the other towns ranged

Digitized by Google

upwards to 22·9 in Salford and Newcastle-upon-Tyne, 24·5 in Manchester, 29·9 in Leicester, and 31·1 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 486 and 673 in the preceding two weeks, further rose last week to 880, owing to the increased mortality from diarrhœa; they included 497 from diarrhœa, 152 from measles, 132 from whooping-cough, 50 from scarlet fever, 25 from "fever" (principally enteric), 23 from diphtheria, and only one from small-pox. No death from any of these zymotic diseases was registered during the week in Halifax, whereas they caused the greatest mortality in Newcastle-upon-Tyne, Preston, and Leicester. The highest death-rates from diarrhœa occurred in Salford, Wolverhampton, London, Leeds, Preston, and Leicester; from measles in Manchester, Birkenhead, and Newcastle-upon-Tyne; and from whooping-cough in London, Birkenhead, and Bradford. The 23 deaths from diphtheria in the twenty-eight towns included 16 in London, 2 in Manchester, and 2 in Newcastle-upon-Tyne. Small-pox caused 1 death in Greater London, but not one in any of the twenty-seven large provincial towns. No case of small-pox was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The mortality from diarrhœa only slightly exceeded the average for the season. The deaths referred to diseases of the respiratory organs in London, which had been 199 and 189 in the preceding two weeks, further declined last week to 188, and were 21 below the corrected average. The causes of 79, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Blackburn, Cardiff, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Newcastle-upon-Tyne, and Bradford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·5 and 18·8 per 1000 in the preceding two weeks, rose again to 19·5 in the week ending July 16th; this rate was 1·2 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 14·6 and 17·3 in Perth and Aberdeen, to 27·3 in Leith and 28·1 in Greenock. The 487 deaths in the eight towns last week showed an increase of 18 upon the number in the previous week, and included 43 which were referred to whooping-cough, 30 to diarrhœa, 11 to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 3 to measles, 1 to diphtheria, and 1 to small-pox; in all, 93 deaths resulted from these principal zymotic diseases, against 85 and 84 in the preceding two weeks. These 93 deaths were equal to an annual rate of 3·7 per 1000, which was 1·3 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 43 and 46 in the previous two weeks, declined again last week to 43, of which 16 occurred in Dundee, 12 in Greenock, 8 in Glasgow, and 5 in Leith. The deaths attributed to diarrhœa further rose, from 10, 18, and 22 in the preceding three weeks, to 30 last week, of which 14 occurred in Glasgow, 5 in Edinburgh, 4 in Paisley, and 3 in Dundee; these 30 deaths were 3 above the number returned in the corresponding week of last year. The fatal cases of scarlet fever further rose from 7 and 8 in the previous two weeks to 11, and included 4 in Glasgow, 3 in Edinburgh, and 3 in Dundee. The 4 deaths referred to "fever" showed an increase upon the low numbers in recent weeks, while the three fatal cases of measles corresponded with the number in the previous week. The death returned from small-pox was one attributed to chicken-pox in Glasgow. The deaths resulting from acute diseases of the respiratory organs in the eight towns, which had been 80 and 76 in the previous two weeks, further declined last week to 65, and were 8 below the number returned in the corresponding week of last year. The causes of 67, or more than 13 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 29·4 and 26·6 per 1000 in the preceding two weeks, rose again to 27·9 in the week ending July 16th. During the thirteen weeks of last quarter the death-rate in the city averaged 28·7 per 1000, the mean rate during the same period being but 18·0 in London and 19·4 in Edinburgh. The 189 deaths in Dublin last week showed an increase of 9 upon the numbers returned in the previous week; they included 28 which were referred to measles, 12 to diarrhœa, 3 to "fever" (typhus, enteric, or simple), 2 to whooping-cough, and not one either to small-pox, scarlet fever, or diphtheria. Thus the deaths resulting from these principal zymotic diseases, which had been 40 and 47 in the preceding two weeks, declined last week to 45; they were equal to an annual rate of 6·6 per 1000, the rates from the same diseases being 6·3 in London and 2·4 in Edinburgh. The fatal cases of measles, which had steadily increased in the preceding ten weeks from 6 to 36, declined again last week to 28. The 12 deaths attributed to diarrhœa showed a considerable increase upon recent weekly numbers; and those referred to "fever" had also slightly increased, while the fatal cases of whooping-cough showed a decline. The deaths of infants were more numerous than in either of the preceding two weeks, while those of elderly persons had further declined. Four inquest cases and 6 deaths from violence were registered; and 38, or rather more than a fifth, of the deaths occurred in public institutions. The causes of 29, or more that 15 per cent., of the deaths registered during the week were not certified.

"Audi alteram partem."

THE RELATIVE RANK QUESTION.

To the Editors of THE LANCET.

SIRS,—I read with much pleasure the letter of "A. M. D." in your issue of May 14th on the above subject. I beg leave to add my humble testimony to its excellence, and only wish that a copy of it were placed in the hands of every young officer of the medical staff, and with it also a copy of your sound and sensible leader on the same subject in the same issue. It is a matter of congratulation that the utter foolishness of this claim for honorary rank has been so well exposed.

Like another of your correspondents, "Army Surgeon," I can speak for many of my brother officers, and say with him, "We do *not* want to be called captains and colonels; we do *not* want to sink our profession by adopting utterly incongruous titles; we do *not* want to become the laughing-stock of the army." I trust that this most mischievous agitation will be stamped out now, once and for ever—this most ignoble and contemptible striving after titles to which we have not a shadow of claim; and I am quite familiar with all the arguments used in favour of it.

I cannot but think that this desire to appear in borrowed plumes, this most illegitimate aspiration, is begotten of a low origin, and nourished in the main by those who very naïvely admit that on retiring from the service they have no position.—I am, Sirs, yours faithfully,

J. P. H. BOILEAU,
Surgeon-Major of twenty-three years' full-pay service.

Punjab, June 20th, 1887.

HEALTH OF MARGATE.

To the Editors of THE LANCET.

SIRS,—Anyone reading your article in last week's issue, founded on Dr. Page's report to the Local Government Board, would certainly draw the conclusion that Margate is a hotbed of fever, and a place which it is not safe to visit. Such an impression, if conveyed by the report, is a false one, and, being most injurious to the town, I trust you will allow me to contradict it. Margate has its faults—offensive privies in the poorer districts, closets often without cisterns, slaughter-houses, and other defects,—but is far from being in the generally unwholesome condition described in your article and in Dr. Page's report.

Last year an epidemic of typhoid fever invaded Margate and most of the neighbouring towns and villages. The epidemic was not limited to Margate only, and this is shown by the fact that the joint hospital for Ramsgate, Margate,

Digitized by Google

and the rural districts received sixty-two cases of typhoid, of which thirty-three came from Margate. Dr. Page does not mention this fact, but it is important as indicating that the disease was due to epidemic causes, and was not entirely endemic, as his report leads the reader to believe.

During the nine years preceding 1886 twenty-five deaths occurred from typhoid fever, inclusive of deaths happening in the Hospital for Infectious Diseases, an average of less than three per annum; in each of two of the years there was only one death. Many of these cases were imported. Is it probable that Margate, frequented during the season by about half a million of visitors, many from the worst parts of London, would under any system of drainage show a materially diminished mortality from this cause? There is in the report no comparison with other seaside towns in this respect. The heading of the report states it to be an inquiry into the continued existence of typhoid fever in Margate. Is it correct to describe a place with this mortality as suffering continuously from typhoid fever? I have read the report carefully, and I cannot find that the general death-rate is given or alluded to; the geological features of the district, and the structure and height of the joint hospital wall are described, but there is no allusion to the general death-rate; the fact is, the death-rate is low, would show favourably for the town, and is omitted. Surely in a report on the general sanitary condition of Margate the death-rate is of some importance, and should be included. I submit that an official report should be impartial, and should convey the whole truth; this report does not do so, and is calculated to reflect credit neither on the Local Government Board nor on the officer who made the inquiry.

The epidemic affected the poorer classes chiefly, and for the most part houses with open privies. There was scarcely an instance of any of the better lodging houses being attacked. I did not, for instance, hear of a single case of typhoid in any of the houses on the sea front.

I had reason to doubt the water supply, and I thought that excessive pumping might suck back impurities which pass into the overflow on its way to the sea. The Town Council, acting on my advice, have dug a new well, whence they get a perfectly pure supply of water; they have not yet altogether abandoned the old well, but as soon as more adits are cut in the new one they will do so. I think with less pumping at the old well they are not likely to exhaust far enough to reach the sources of pollution.

The lower levels of Margate for the most part drain into the sea; the remainder of the houses and those of the higher ground drain into cesspools. We are condemned for these, and they are supposed to contaminate the subsoil by soakage. If, however, the chalk close to a cesspool be examined, it is found to be white, clean, and without smell. Scientific opinion is against cesspools, but in Margate, where the houses are not crowded, 3067 houses in 995 acres, they have answered fairly well. We escape, at any rate, soil pipes under the basements, and faulty plumbing out of sight, also the nuisance of street gratings and ventilators.

Facts, however, are better than arguments, and the following figures I am prepared to substantiate: 1. There is not at the present time a single case of typhoid fever in Margate. I append to my letter copy of certificate from the medical practitioners to this effect. 2. In a population of 13,000 there were only 144 deaths during the half-year ending June, 1887, giving a gross death-rate of 16 per 1000 per annum. Deducting fifteen deaths which occurred in hospitals and ten among visitors, the death-rate is 13·2 per 1000. 3. There were but three deaths from zymotic disease in Margate during the half-year, in addition to one in the joint hospital. The deaths were due—two to diarrhœa, one to [illegible] fever, and one to croupous laryngitis. There was no [illegible] from zymotic disease within the radius of the town [illegible] during the last quarter ending June, 1887.

These facts need no comment, and if any of your readers would like to verify them, I shall be pleased to enable them to do so.

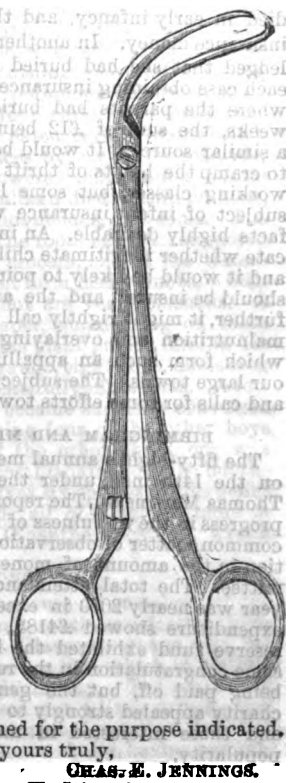
I am, Sirs, your obedient servant,

WM. KNIGHT TREVES, F.R.C.S.,
Medical Officer of Health for the Borough of Margate.

[illegible] comprising the whole number of [illegible] practising in Margate, hereby certify that at the present time any case of typhoid fever under our care in the borough of Margate, and that, to the best of our belief and knowledge, there is not a single person suffering from typhoid fever within its radius.

(Signed)	A. NORTON TAYLOR.	WM. PRICE.
	A. W. SCATLIFF.	F. E. NICHOL.
	ARTHUR ROWE.	GEO. M. PITTOCK.
	T. SMITH ROWE.	E. A. WHITE.
	WM. KNIGHT TREVES.	ROBT. THOMSON.
	BERTRAM THORNTON.	AMBROSE WILLY.
	ROBT. PETTICREW.	W. W. COLBOURNE.

Dated this 18th day of July, 1887.



I certify the above to be a correct copy.
WM. KNIGHT TREVES.

*** Notwithstanding this letter, we are compelled to regard the sanitary condition of Margate as very unsatisfactory; and nothing but the abolition of cesspools, the provision of a proper system of drainage and of a safe water supply, will make Margate fit to be regarded as a first-class health resort.—ED. L.

"TRACHEOTOMY AND INFLATION IN THE TREATMENT OF A STILLBORN CHILD."

To the Editors of THE LANCET.

SIRS,—Referring to Dr. Watson's interesting paper in your issue of to-day, permit me to remark that asphyxia in newly-born children is due to the fact that during inspiratory efforts the epiglottis is drawn down like a valve over the superior orifice of the larynx, so that air cannot obtain access to the lungs. The manner in which asphyxia thus arises can be readily demonstrated by examining the throat of a dog whilst under the influence of anæsthesia, in which animal the epiglottis and upper part of the larynx can be seen with the naked eye. As the result of this observation it is clear that the form of asphyxia under consideration can be prevented by drawing the epiglottis forward with a forceps.[1] This manœuvre being of the greatest importance, because it dispenses entirely with the necessity for tracheotomy, perhaps you will not object to reproduce from my article[2] the drawing of my forceps for the epiglottis, which I specially designed for the purpose indicated.

I am, Sirs, yours truly,

CHAS. E. JENNINGS.

Upper Brook-street, Grosvenor-square, W., July 16th, 1887.

"SURVIVANCE AFTER GUNSHOT WOUNDS OR OTHER INJURIES OF THE HEART."

To the Editors of THE LANCET.

SIRS,—Under the above heading are some very interesting cases collected by Dr. Curran; I should like to add one to the number. About twelve years ago, being in New Zealand, I was one day walking across a plain, having a sporting Snider rifle with me, but no dogs. Presently I saw a large wild boar trotting gently across the open at about 250 yards distance from me, and showing a good broadside. I knelt down and fired at him, and felt sure I had hit him. He, however, turned sharp round at the shot and immediately charged straight down upon me at a tremendous pace. I instantly reloaded and reserved my fire for a close shot, when within

[1] THE LANCET, 1885, vol. i., p. 291. [2] Loc. cit.

Digitized by Google

thirty yards he suddenly went head over heels, and running up to him I found him stone dead. Curiosity made me carefully open the thorax. I found the lower third of the heart completely torn away, right and left ventricles being cut in half, and the two sets of valves exposed. I found the bullet, quite flattened, under the skin of the opposite side. Passing through the shield and impinging against a rib on the near side had flattened the bullet, which had then cut through the heart like a knife.

I am, Sirs, yours obediently,
JOHN A. FRANCIS, M.R.C.S., L.S.A.

Southsea, July 19th, 1887.

BIRMINGHAM.

(From our own Correspondent.)

INFANT LIFE INSURANCE.

FIVE inquests held in one day on the bodies of infants calls for more than usual attention, even from those indifferent to the ordinary value of life. Coupled with the question of infant life insurance, it affords material for grave reflection. In one of the cases reported the mother admitted that two of the three iligitimate children she had borne had died in early infancy, and that in both she had received insurance money. In another instance the mother acknowledged that she had buried five out of seven children, in each case obtaining insurance money. Still another instance where the parents had buried three children in as many weeks, the sum of £12 being the amount obtained from a similar source. It would be manifestly wrong to attempt to cramp the habits of thrift and independence among the working classes, but some legislative interference on the subject of infant insurance would be in the face of these facts highly desirable. An inquiry of this kind might indicate whether illegitimate children ought to be insured at all, and it would be likely to point out the ages at which infants should be insured, and the amounts to be received. Going further, it might rightly call attention as to the influence of malnutrition and overlaying in producing these disasters, which form such an appalling feature in the mortality of our large towns. The subject is one of national importance, and calls for some efforts towards a solution and a remedy.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.

The fifty-eighth annual meeting of this charity was held on the 14th inst., under the presidency of the Mayor, Sir Thomas Martineau. The report showed a steadily increasing progress in the usefulness of the charity, but, as is getting a common matter of observation in these bad times, a diminution in the amount of money at the disposal of the committee. The total attendances of out-patients during the year was nearly 2000 in excess of the previous year. The expenditure showed £4183, and the income £3829. The reserve fund exhibited the low sum of £12. There was some congratulation in the remainder of the building debt being paid off, but the general financial position of the charity appealed strongly to the support of the benevolent and those interested in maintaining its usefulness and popularity.

BIRMINGHAM KYRLE SOCIETY.

A meeting of those interested in the formation of recreative evening classes for the education of children who have left the elementary schools was held lately, and was well attended. Considerable success has attended the movement in this town, and its objects cannot be too highly commended. The efforts to make education interesting and agreeable cannot be too strongly advocated. The proposals embraced subjects such as musical drill, cooking, dressmaking, knitting, imaginary shopkeeping, athletics, wood carving, inventive drawing, elocution, and dramatic reading, with a number of other subjects calculated to promote utility, ornament, and occupation. It is to be hoped that means will be provided, and teachers found to carry out this laudable work, in which the pursuit of work and pleasure can be so advantageously combined, with good results to the growing population.

CARDINAL NEWMAN.

The many admirers of His Eminence Cardinal Newman will be pleased to know of his unabated mental vigour and general health. Though now in his eighty-sixth year, physically feeble, and unable to walk with ease, he continues to work with system and regularity in his daily life. At the annual play of the Oratory School, in which the Cardinal's adaptation of Terence's play of "Pincerna" was performed, the venerable Cardinal sat through the whole of the time, and was apparently much interested in the manner in which the pupils played their parts.

Birmingham, July 20th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE ROYAL WEEK IN NEWCASTLE.

THE great Cattle Show held here under the auspices of the Royal Agricultural Society of England last week has proved a great success. Except on the last day the weather was all that could be desired. On the first popular day nearly 80,000 persons paid for admission. The North-Eastern Railway alone brought 60,000 passengers into the city. The show on the whole attracted more than 126,000 visitors, being about 12,000 more than the previous one held in this city about twenty-three years ago. The Mining and Engineering Exhibition had also a good week, receiving about 120,000 visitors. The whole passed off without a single serious accident to mar the week's festivities.

NEWCASTLE HOSPITAL FOR INCURABLES.

A new departure was made at this very useful charity last week, when the Charities' Committee of the Newcastle Corporation, who are its governors, gave a very successful garden party to their friends, and at the expense of the members of the committee, so as in no way to trench upon the resources of the charity, which, as I told you in a previous letter, are derived from the revenues of an ancient charity founded for the benefit of lepers. The hospital at the present has about thirty inmates, and Mr. J. A. Angus is the medical superintendent. He, in the course of the afternoon, conducted suitable parties of the visitors over the hospital, and introduced them to the patients. The idea of the garden party was to enlist the sympathy of the public, and let them see the good work done by the hospital; and it was properly considered that the entertainment would have a good and cheering effect on the patients, as showing them that they were not altogether cut off or isolated from outside feeling, especially as no pecuniary aid was required. I do not know who thought first of the party; but, at all events, it was a happy and humane idea; and Mr. Angus, who is distinguished by his kindness to the poor, is to be congratulated on the result.

THE CHINESE SEAMEN IN THE TYNE.

The transport *Too Nan* has now left the Tyne for Germany, with some 300 native Chinese sailors on board, and, I believe, in fair health; but Dr. Slater informs me that more than 300 have been left behind to take out from the Tyne two steam cruisers now receiving their armaments at the Elswick ordnance works. It is announced that a portion of the crews are to join in some military sports in North Shields this evening, on the invitation of Colonel Pilter, and the Chinese Admiral Lang, in his reply, consents to his men entering into a competition among themselves at a feat, the object of which is to throw very heavy weights into the air and catch them on their descent. This is a trial of strength which is very common in the northern provinces of China, from which many of the seamen come.

NEWCASTLE ROYAL INFIRMARY.

A conference of the working men's delegates has been held with the infirmary subcommittee, and it has been arranged that for each £10 subscribed annually a governor may be elected. It has also been recommended that all honorary medical officers are to be in future governors *ex officio*.

Newcastle-on-Tyne, July 19th.

SMALL-POX EPIDEMIC AT ABERDEEN.—The outbreak of small-pox which was reported to have occurred in Aberdeen about the beginning of June has within the last few days exhibited such a tendency to spread that the Public Health Committee of the town has decided to erect two special wards at the City Hospital for the treatment of patients.

EDINBURGH.

(From our own Correspondent.)

UNIVERSITY COURT MEETING.

A MEETING of the University Court took place on Monday, the 18th inst., at which Dr. Heron Watson, the recently elected Assessor for the General Council of the University, took his seat for the first time. There was a good deal of routine business gone through, and certain points of greater general interest and importance were also considered, among them the representation of the General Council of the University, adopted at a stormy meeting of that body some months ago, asking for a "consideration of the sound construction of the Universities Act, 1858, read along with the Medical Acts, 1858 and 1886, relative to the election of the representative of the University in the General Medical Council." It has been urged, with some show of reason, that the General Council of the University should carry out the functions of an electorate in this respect as representing the University in its widest sense. Precedent, on the other hand, and a strong conservative instinct among its members, would point to the Senatus Academicus as the proper electing body. In the circumstances, specially in view of the strong public feeling on the question, the Court has done wisely in deciding to take counsel's opinion on the sound interpretation of the Acts under consideration. The point is a purely legal one, and can be best settled by the dispassionate judgment of a legal expert. Amongst other matters, the Court considered and approved the report of the Committee in charge of the University library, which was of a satisfactory nature, and reflected credit on Mr. Webster, the lately appointed librarian, whose energy and intelligence are doing much in developing the usefulness of the library.

THE ROYAL SOCIETY OF EDINBURGH.

The last meeting of the session was held last Monday, when a number of papers were read, and the work of the session brought to a close by an address from the Vice-President, Sheriff Irvine, who occupied the chair. His statement of work done was highly satisfactory, and shows that the Society is in a flourishing condition. A Victoria Jubilee prize, founded by Dr. Gunning, and amounting to 100 guineas annually, has been this year awarded to Sir William Thomson, President of the Society, for his remarkable series of papers on Fluid Motion. One of the papers read on Monday was of considerable meteorological interest. It is a record of observations made by Mr. Stack, assistant at the Ben Nevis Observatory, on the temperature of winds. The observations were made with an apparatus called the "thermic windrose." Not only were the maximum and minimum temperatures of the various winds measured, but their range of rise and fall in temperature in the different seasons was in each case recorded. The warmest is found to be south wind; the coldest the north-east wind; while that from the south-east has the greatest range of temperature, representing a variation of 24·3° between the maximum and minimum recorded.

THE EDINBURGH UNIVERSITY UNION.

The Students Union, on behalf of which there have been such loyal exertions among present and former students and their friends, is now to be commenced. An estimate of £10,000 for the cost of the buildings has been accepted by the Buildings Committee, and the work will proceed at once, the site having been already acquired.

THE DISCUSSION ON SCARLET FEVER.

The Medico-Chirurgical Society is to hold its meeting for the discussion on Scarlet Fever to-morrow, the 20th inst. The discussion is to be opened by Dr. W. Allan Jamieson, physician to the City Fever Hospital, and it is understood that the question of the origin of epidemics will be largely dealt with, in connexion with the recent violent outbreak of the disease in this city. The higher etiology is also to be to some extent discussed. It is reported that the committee appointed to look into the question in relation to [illegible] Billington's researches have not been able to come to a definite conclusion, and will only present a preliminary statement of their work.

GLASGOW.

(From our own Correspondent.)

POISONING CASES.

A NUMBER of serious cases of poisoning have occurred in Glasgow and its vicinity lately. About a fortnight ago, in Pollokshaws, eight children suffered from arsenical poisoning, and of these two died, the others recovering only after very prompt and energetic treatment. They had picked up in the street a quantity of a white, crisp substance, which they took for alum, but which consisted almost entirely of arseniate of soda. The symptoms presented were typically those of arsenical poisoning. At Whiteinch, one of the western suburbs of Glasgow, about twenty children were reported as being more or less ill from eating "jubilee shortbread," which they had bought at a stand in the street. The symptoms complained of were those of some powerful gastro-intestinal irritant—vomiting, pain, purgation, and collapse. No death occurred. The nature of the poisonous ingredient in the shortbread has not been made out, but it is supposed that it was either nitrate of potassium or carbonate of ammonia; the latter is often used by pastry bakers, and may have been impure or excessive in quantity. The fact that the symptoms were due to the cakes eaten was proved by an experiment, which may be commended to the attention of anti-vivisectionists. The father of one of the children who suffered gave a cake to a dog, which, by promptly turning sick and vomiting copiously, gave evidence of the poisonous nature of what had been eaten. At Greenock, four children showed very serious symptoms after having eaten certain roots which they had dug up in marshy places by a country roadside, under the impression that they were "ladies' nuts," a kind of "earth nut." One of the children died within an hour, after suffering from vomiting, convulsions, and coma. The other three children recovered. The roots eaten are supposed to have been those of Œnanthe crocata, one of the water-dropworts. The roots of this plant form fleshy knobs, which are not unpleasant to the taste, but are very poisonous. A correspondent of a local newspaper, commenting on these cases, gives instances in which this plant proved fatal in its effects. "At Clonmel, some years ago, eight boys, mistaking this plant for wild celery, ate plentifully of its roots. A few hours afterwards the eldest boy became suddenly convulsed and died; and before next morning four of the other boys died in a similar manner. Of the other three, one was maniacal several hours; another lost his hair and nails; but the third escaped unhurt. Hooker gives six species of this genus as native of the British Islands, all of which are more or less poisonous, but he mentions Œnanthe crocata as 'a rank poison.'"

JUBILEE HONOURS.

The distribution of jubilee honours to members of the profession in Glasgow has given much satisfaction here. Sir George Macleod is the first Glasgow surgeon who has received the honour of knighthood, a title which in his case will be worn worthily and with dignity. The absence of another name from the list caused not a little surprise, and even irritation; but it is satisfactory to learn that Professor Gairdner remains untitled of his own choice, having respectfully declined an honour similar to that conferred on his colleague; he does this for reasons which, as he himself puts it, "do not in the least affect his grateful reception of Her Majesty's message as a token of goodwill, or his hearty congratulations to friends who have been the recipients of like distinction." Another mark of the esteem in which Dr. Gairdner is universally held has been accepted by him however—namely, the degree of M.D. (*honoris causâ*), conferred on him recently by the University of Dublin.

THE VICTORIA INFIRMARY, GLASGOW.

This hospital, formerly known as the Southern Hospital, is now to be known by the above title, having received Her Majesty's consent thereto in recognition of her jubilee year. The scheme for its erection progresses favourably. Money is being subscribed with fair rapidity, about £13,000 having been already received. When the sum of £15,000 is reached building operations will commence. Various meetings have been held in the southern suburbs of Glasgow, such as Pollokshields and Rutherglen, and at these the cause of the

Digitized by Google

infirmary has been enthusiastically adopted. It is hoped that the foundation-stone of the building may be laid next year, and possibly by some member of the Royal Family, as our exhibition building will be ready for a similar ceremony about the same time.

BURGH POLICE AND HEALTH (SCOTLAND) BILL.

This unfortunate Bill has been shelved again. The Convention of Royal Burghs having brought this measure again under the notice of the Secretary for Scotland, and having represented its extreme importance and urgency, have received from Lord Lothian an intimation, "that owing to the state of public business the Bill cannot be introduced this session with any possible chance of its becoming law." This is the more regrettable as the measure has already passed in separate sessions third readings in both Houses of Parliament, and has been favourably reported on by a Select Committee of each House, and, indeed, a common understanding had been arrived at by those interested in its provisions, so that it was expected that it might pass without serious opposition. Meanwhile the sanitary law of Scotland stands just as it did twenty years ago.

GLASGOW ROYAL INFIRMARY MEDICAL SCHOOL.

At the close of the summer session yesterday, Dr. Macintyre was presented with a handsome marble dining-room clock, with suitable inscription, and statuettes, as a mark of the esteem in which he is held by the medical students who have been attending the classes in this institution. Dr. Clark, dean of the school, presided.

Glasgow, July 20th.

DUBLIN.

(From our own Correspondent.)

THE CONJOINT EXAMINATION SCHEME.

COMPLAINTS are numerous about the *viva-voce* part of the examination in physics at the first professional examination held recently under the conjoint scheme. It is alleged that the questions in this subject were mostly outside the prescribed course of examination. Certainly the rejections were so excessive that no other explanation appears to be tenable, and it seems that the examiners—and I do not exclude those in anatomy—expected too much from the candidates who came before them.

OPHTHALMIA IN THE CORK WORKHOUSE.

For a considerable time past eye diseases have been prevalent among the children in this workhouse, but recently it has reached such proportions that Dr. Sandford has been requested to report on the matter to the Board of Guardians. He states that in the boys' school 74 per cent. of the pupils are suffering from affections of the eyes, of greater or less severity. In the girls' school 80 per cent. are affected, while in the infants' school 6·3 per cent. have some form of eye disease. In both the boys and girls in hospital the majority of the patients are sufferers from ophthalmia. With few exceptions the disease takes the form of granular ophthalmia and its complications, and is in many instances associated with other scrofulous affections. It varies in severity from the latent forms, in which its presence is not apparent except by close examination, to an unsightly condition in which the eyes are a mass of disease, and vision is hopelessly impaired or destroyed. In the boarded-out children, on the other hand, there were only 2 cases in over 100 children. The prevalence of the disease in the chronic form is due to various causes, one of the most important being its communicability from one child to another by direct contact. A number of children are crowded together, most of whom are constitutionally predisposed to the reception of such an affection, the chances of the spread of infection being enormously increased by the use of a common lavatory, the same towel or roller being used by a number of children. Under such circumstances the introduction of one case into a school previously free from disease would render its contraction by the other children almost a certainty. Once contracted, the nature of the disease is to assume a chronic form—kept alive by favourable surroundings, such as overcrowding, insufficient ventilation or improper food, and breaking out at times into an active condition when stirred by some special stimulus or local irritation, such as exposure to cold or wet, to dust or rain. It is to be hoped that the disease may be effectually stamped out by acting on the admirable suggestions made by Dr. Sandford.

ZYMOTIC DISEASES IN DUBLIN.

During the five weeks ended July 2nd, the mortality from measles was doubled as compared with the previous month, but, on the other hand, there was a marked decline in the number of deaths from whooping-cough. It is interesting to note (the occurrence being most unusual) that there was not a single fatal case of typhus fever recorded during the month. Measles, it may be added, is still prevalent in Dublin. Last week 36 deaths were ascribed to this disease, and there are 141 cases under treatment in hospital.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

Her Majesty, who is patron of this Society, having completed the fiftieth year of her reign, it has been suggested that a special Jubilee collection should take place. About £100 has already been contributed towards the fund in question, and the amount, when complete, will be distributed, in honour of the occasion, to the many annuitants relieved by the operations of this charitable Society.

Mr. Broomfield, of the Carmichael College of Medicine, has been presented with an address and testimonial on the occasion of his approaching marriage.

Dublin, July 19th.

THE SERVICES.

Deputy Surgeon-General R. Hungerford has been appointed Principal Medical Officer, Eastern District, vice Surgeon-General Fox, now at Aldershot, and Deputy Surgeon-General S. A. Lithgow, M.D., C.B., has been appointed Principal Medical Officer of the South-Eastern District.

WAR OFFICE.—Army Medical Staff: Deputy Surgeon-General Sir James Arthur Hanbury, K.C.B., M.B., F.R.C.S.I. to be Surgeon-General, vice J. O'Nial, C.B., granted retired pay (dated June 14th, 1887); Deputy Surgeon-General Randolph Webb, from half-pay, to be Deputy Surgeon-General, vice Sir J. A. Hanbury, K.C.B., M.B., F.R.C.S.I. (dated June 14th, 1887); Surgeon Norman Smyth, M.D. resigns his commission (dated July 20th, 1887).

YEOMANRY CAVALRY.—West Somerset: Surgeon S Farrant is granted the honorary rank of Surgeon-Majo (dated July 16th, 1887).

ARTILLERY VOLUNTEERS.—2nd Volunteer (Devonshire) Brigade, Western Division, Royal Artillery: E. Holberto Edlin, Gent., to be Acting Surgeon (dated July 16th, 1887) Honorary Assistant-Surgeon G. Miles resigns his commissio (dated July 20th, 1887).—1st East Riding of Yorkshire Thomas McCraith Foley, Gent., to be Acting Surgeon (date July 20th, 1887).

ENGINEER VOLUNTEERS.—1st Cheshire: Acting Surgeo Andrew Stewart is appointed Second Lieutenant (dated Jul 20th, 1887).—2nd West Riding of Yorkshire (Leeds): Charle Malcolm, Gent., to be Acting Surgeon (dated July 20t 1887).

VOLUNTEER SUBMARINE MINERS (the Tees Division).— William Jones Williams, M.D., to be Acting Surgeon (date July 20th, 1887).

RIFLE VOLUNTEERS.—1st Volunteer Battalion, the Queen Own (Royal West Kent Regiment): Acting Surgeon Eyr Ievers, M.D., resigns his appointment (dated July 16th, 1887

Medical News.

YELLOW FEVER.—Reports are current in Ne York of an alarming prevalence of yellow fever at Memphi Tennessee.

AN epidemic of hysteria is reported to have broke out amongst the women at Agosta, a populous village ne Subiaco.

NEW FRENCH HOSPITAL.—His Royal Highness t Comte de Paris has given a donation of £100 to the buil ing fund of the new French Hospital which is to be erect in Shaftesbury-avenue. Her Royal Highness Madame Comtesse de Paris has paid, for the same fund, to t bankers of the institution the sum of £600, being a share the proceeds of the bazaar held at Willis's Rooms in June.

Digitized by Google

THE SHEFFIELD WATERWORKS.—At a special meeting of the proprietors of the Sheffield Waterworks, held on the 11th inst., the terms of agreement recommended by the directors for the sale of the undertaking to the corporation were unanimously confirmed. These terms are equivalent to a purchase price of rather over £2,000,000. The Corporation Bill seeking the power of purchase is now before Parliament, and is expected to pass as an unopposed measure.

THE HEAT IN THE UNITED STATES.—The heat throughout the United States on the 16th inst. was unusual and extreme. The following figures show the temperatures recorded: Pittsburg, 101°; Washington and Baltimore, 99°; Pekin (Illinois), 103°; Joliet (Illinois), 113°; St. Louis, 107°; Chicago, 102°. The 17th inst. was the hottest day known at Philadelphia, with one exception in 1876, for thirty years. On the 18th the excessive heat continued, and many deaths from heat have, as might be expected, occurred.

GUY'S HOSPITAL.—On the 19th inst. a meeting of the subscribers to the Special Appeal Fund on behalf of this institution was held, when it was reported that the fund now amounted to £75,000. After paying off a debt to the bank, a sum of £60,000 was left. The interest of this sum, however, is not sufficient to maintain the 500 beds, but it is hoped that it will be possible to save the principal, and that with increased subscriptions in the future the work of the hospital may be satisfactorily carried on.

TESTIMONIAL TO MR. GODART.—On Monday, the 18th inst., in the presence of the staff and a large number of the past and present students of St. Bartholomew's Hospital, Mr. Savory presented a testimonial to Mr. Godart, upon the occasion of his departure for Sydney. In an eloquent address, Mr. Savory alluded to Mr. Godart's long connexion with the school of St. Bartholomew's Hospital, and concluded by presenting him with a gold watch and a purse containing fifty guineas from his friends amongst the past students and staff of the hospital, and a testimonial, illuminated on vellum, and signed by the consulting and acting medical and surgical staff.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—Sir James Paget, president, took the chair at the quarterly court of directors of this Society, held on Wednesday, July 13th. One member was elected, the deaths of four were reported, two gentlemen had ceased to be members, and the election of another was declared void. A sum of £1384 was voted for distribution amongst sixty-four widows and nine orphans. The application of a widow was considered, and a grant made. The expenses of the quarter were £37 odd. The treasurer reported the receipt of the legacy of £5000 from the executors of the late Sir Erasmus Wilson, a vice-president of the Society.

AFTER-CARE ASSOCIATION.—The annual meeting of this Association, founded for the benefit of poor and friendless female convalescents on leaving asylums for the insane, was held on Thursday last, at 83, Lancaster-gate, W. In the absence of Lord Meath, Dr. Hack Tuke took the chair. The meeting was addressed by the Rev. C. J. Ridgeway, Rev. E. S. Derrick, Dr. Geo. H. Savage, Dr. T. Claye Shaw, Dr. S. Russ Philipps, and others. A fair amount of progress had been made during the past year, but funds are much wanted to extend the work of the Association. There are about 30,000 women of various callings and conditions of life in lunatic asylums in England and Wales. Full information of this valuable work may be obtained of the secretary, Mr. Thornhill Roxby, Emblewood, Osbaldiston-road, N.

MEDICAL NOTES IN PARLIAMENT.

Army Medical Officers.

IN the House of Commons, on the 14th inst., in answer to Dr. Tanner, Mr. Stanhope stated that the reduction in the troops in Egypt had resulted in a temporary excess of medical officers in various military districts, of which Cork was one, and all military medical officers not exclusively employed in the station hospital are available for duty in barracks. The number on the roll at Cork on May 30th was fourteen, of whom two were on leave; and on the same date there were eighty sick in the station hospital. It is the practice to place one medical officer on orderly duty each day, so that with twelve officers available the turn of each would come round every twelfth day. The usual term of rotation depends on the number of officers, which for Cork (exclusive of Cork Harbour) is eight. The other officers, although not on duty, are all employed. He added that in consequence of the present temporary excess admission to the medical staff has been suspended until the supernumeraries are absorbed.

Contagious Diseases in the Colonies.

In answer to Mr. Stuart, Sir H. Holland said that the colonies in which contagious diseases ordinances were in force in October last were Jamaica, Trinidad, Barbadoes, Labuan, Ceylon, Hong-Kong, the Straits Settlements, Malta, and Fiji. In Jamaica, Trinidad, and Barbadoes repealing laws have been passed, which have been confirmed. In Labuan the ordinances have been suspended, and their repeal has been ordered. In Ceylon, Hong-Kong, and the Straits Settlements the Governors have been directed to introduce measures repealing the ordinances, but there has not yet been sufficient time to carry out the instructions. In the case of Malta the Governor has been instructed to invite the Council to follow the example of the United Kingdom in this matter. In Fiji, in view of the special circumstances affecting the health of the native population, and especially in consequence of the coolie immigration from India, he has decided not to press for the immediate repeal of the ordinances. In the case of Gibraltar, where there is no ordinance, the Governor has been directed to put an end to the system of the examination of women. In St. Helena the ordinance of 1865 was allowed to lapse in 1879.

Alleged Ill-treatment of a Lunatic.

On the 19th inst., Mr. W. Corbet asked the Secretary of State for the Home Department what was the result of his inquiries into the alleged ill-treatment of a lunatic in Stafford Goal.—Mr. Matthews replied that he had received a report from the Prisons Commissioners of the inquiry which has recently been held at Stafford Gaol, and which was conducted by the visiting committee assisted by an inspector. The inquiry as a whole is not yet complete, but it appeared from the report to be clear that the injuries which were found upon the man were self-inflicted, that no violence was done to him by the prisoners with whom he was placed, and generally that the amount of the injuries had been much exaggerated. Further investigation would be made as to whether all was done that should have been done to prevent the prisoner from injuring himself. At the same time there was no doubt but that the magistrates committed an error of judgment in sending him to Stafford Gaol, for his mental condition showed that he should have been removed at once to an asylum.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ADIE, A. J., L.R.C.P.Lond., L.S.A., has been appointed Resident Obstetrical Officer to Charing-cross Hospital.

BARTON, G. P., L.S.A., has been appointed House-Physician to Charing-cross Hospital.

BOWER, B. J., M.R.C.S., L.R.C.P.Lond., L.S.A., has been appointed House-Surgeon to Charing-cross Hospital.

HAYNES, SYDNEY W., M.B., C.M.Ed., has been appointed an Honorary Administrator of Anæsthetics to the Birmingham Dental Hospital.

HODGSON, JOHN, M.B.Lond., M.R.C.S., has been appointed Assistant Surgeon to the Oldham Infirmary.

LINGWOOD, E. H., L.S.A., has been appointed House-Physician to Charing-cross Hospital.

LITTLEWOOD, J. O., L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Walsall Borough District of the Walsall Union.

MAITLAND, EDWARD W., L.R.C.P.Ed., M.R.C.S., has been appointed Assistant Surgeon to the Oldham Infirmary.

PEDLEY, F. NEWLAND, F.R.C.S., L.D.S., has been appointed Senior Dental Surgeon to Guy's Hospital, vice Moon, resigned.

ROBERTS, THOMAS H., L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Township of Saddleworth.

SANDELL, H. W. A., L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Upper District of the Leighton Buzzard Union.

SILK, J. FREDK, W., M.D., has been appointed Anæsthetist to the National Dental Hospital.

SMITH, E. J., M.R.C.S., L.S.A., has been appointed House-Surgeon to Charing-cross Hospital.

STONHAM, CHARLES, F.R.C.S., has been appointed Assistant Surgeon to Westminster Hospital, vice A. M. Sheild, resigned.

WILDERS, JOHN ST. S., M.R.C.S., L.S.A., has been appointed Honorary Consulting Surgeon to the Birmingham Dental Hospital, vice Furneaux Jordan, resigned.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BELGRAVE HOSPITAL FOR CHILDREN, Gloucester-street, S.W.—House-Surgeon. Salary at the rate of £20 per annum, with board, &c.

BIRMINGHAM GENERAL HOSPITAL.—Resident Medical Officer. Salary £130 per annum, with residence, board, and washing.—Two Assistant House-Surgeons. No salary, but residence, board, and washing will be provided.

CARLISLE DISPENSARY.—Junior House-Surgeon. Salary £100 per annum, with apartments (not board).

GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury, Manchester.—Senior and Junior Resident Officers. Salary £100 and £80 per annum respectively, with apartments and board.

Digitized by Google

LAMPETER UNION.—Medical Officer, Medical Officer of Health, and Public Vaccinator. Salaries and fees about £80 per annum.

LONDON FEVER HOSPITAL, Liverpool-road, N.—Assistant Resident Medical Officer. Salary £120 a year, with board.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, Berner's-street, W.—Resident Librarian. Salary commences at £250 per annum, to which are added residence, coals, and gas.

WEST NORFOLK AND LYNN HOSPITAL, King's Lynn.—House-Surgeon and Secretary. Salary £80 per annum, rising by annual increments of £10 to £100 per annum, with residence, board, washing, and attendance.

Births, Marriages, and Deaths.

BIRTHS.

DUNLOP.—On the 10th inst., at Long Sutton, the wife of J. Gordon Dunlop, M.B., of a daughter.

JAMES.—On the 16th inst., at Butler House, Kilkenny, the wife of C. E. James, B.A., M.B., T.C.D., L.R.C.S.I., of a son.

MACKERN.—On the 13th inst., at Calle Lavalle, Buenos Ayres, the wife of George Mackern, M.D.Lond., M.R.C.S., of a daughter.

MARSH.—On the 14th inst., at Grasmere, Rotton-park-road, Edgbaston, the wife of F. Marsh, F.R.C.S., of a daughter.

PECK.—On the 18th inst., at Gower-street, the wife of Awdry Peck, M.A.Oxon., M.R.C.S., L.R.C.P., of a son.

PESKETT.—On the 17th inst., at Oakover, Burnham, Somerset, the wife of A. W. Chalmers Peskett, M.A., M.B., B.C.Cantab., of a daughter.

PRESTON.—On the 16th inst., at Liskeard, Cornwall, the wife of George Preston, M.R.C.S., L.R.C.P., of a son.

TOWNSEND.—On the 15th inst., at Jalapahar, Darjeeling, the wife of Surgeon-Major Townsend, A.M.S., of a daughter.

MARRIAGES.

BLATHERWICK—FRANKS.—On the 19th inst., at St. Peter's, Streatham, by the Vicar, the Rev. A. C. Tarbutt, M.A., assisted by the Rev. Charles G. Gull, M.A., Henry Blatherwick, M.R.C.S., L.R.C.P., of Woodlawn, Dulwich Village, second son of Deputy Surgeon-General Blatherwick, of Southampton, to Kate Temple, only daughter of the late J. F. Franks, of Streatham-common, and Catherine S. Temple Franks, of Crown-hill, Norwood.

BRENCHLEY—SPURLING.—On the 15th inst., at St. Giles's, Camberwell, Algernon Brenchley, M.D., to Marion, eldest daughter of Henry John Spurling, of De Crespigny-park, S.E.

EDSELL—HAINES.—On the 14th inst., at St. Mary's Church, Byfleet, George Alfred Edsell, L.R.C.P., M.R.C.S., to Annie Isabel, eldest daughter of William Haines, Esq., of Coleman-street, E.C., and The Cedars, Byfleet, Surrey.

GOLLAND—REID.—On the 19th inst., at St. John's, Altrincham, by the Rev. C. E. Golland, M.A., brother of the bridegroom, assisted by the Rev. P. Wainwright, M.A., Vicar of the Parish, Alfred Golland, M.R.C.S., L.R.C.P.E., of Altrincham, to Mary (Minnie), third daughter of Alexander Reid, Esq., of Woodlands-park, Timperley.

GRIFFIN—STROTHER.—On the 14th inst., at Shaugh Prior Church, Roborough, South Devon, Richard Michael Griffin, M.B., M.Ch., to Mary Julia, daughter of the Rev. James Baxter Strother, M.A., Vicar of Shaugh Prior.

PARKHILL—ABBOTT.—On the 12th inst., at St. Giles's, Reading, by the Rev. C. F. J. Bourke, Samuel J. Parkhill, M.D., of Church Gresley, Derbyshire, to Lydia (Dick), daughter of the late Charles W. Abbott, of Marlpool, Derbyshire, and niece and adopted daughter of the late Wm. Carrick Crofts, M.R.C.S.Eng., of Church Gresley.

WAYLEN—LEAKE.—On the 2nd ult., at St. George's Cathedral, Perth, Western Australia, Alfred Robert Waylen, M.D., Colonial Surgeon and Principal Medical Officer, to Louisa, widow of the late Sir Luke Samuel Leake, Speaker of the Legislative Council of Western Australia.

WEARING—COMER.—On the 7th inst., at St. Margaret's, Anfield, Liverpool, by the Venerable the Archdeacon of Man, assisted by the Rev. C. S. Nicholl, Richard Wearing, M.D.Edin.Univ., of Wavertree, to Helena Blanche, younger daughter of George Comer, of Larkfield, Wavertree.

DEATHS.

BAZELEY.—On the 17th inst., at Queen Anne-terrace, Plymouth, Wm. Bazeley, M.R.C.S., L.S.A., aged 49.

DAWSON.—On the 14th inst., at his residence, Regent-street, Great Yarmouth, John Dawson, M.D., aged 46.

LYONS.—On the 13th inst. (of phthisis), on board s.s. *City of Bombay*, while entering the docks, Thomas Lyons, L.R.C.P., L.S.A., Civil Medical Officer, Bogra, India, aged 47.

RONALD.—On the 17th inst., at Wellington-square, Ayr, N.B., John Ronald, C.M.Glas., J.P., in his 84th year.

ROSE.—On the 14th inst., at Diss, Norfolk (of apoplexy), Fredk. Robert Rose, M.R.C.S., L.S.A., in his 78th year.

YOUNG.—On the 28th ult., at Hastings, Thomas Young, L.R.C.P.Ed., L.R.C.S.Ed., L.F.P.S.Glas., L.M. (brother of G. W. Young, Surgeon, of East Ardsley, near Wakefield), aged 34. (Deeply lamented.)

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE VALUE OF THE SUNFLOWER.

IT is stated on the authority of a Cuban journal that since the sunflower has been cultivated in certain swampy districts on the banks of the river Potomac malarial fever has almost ceased to be endemic there. Similar beneficial results appear also to have followed the cultivation of this plant in the neighbourhood of the mouth of the Scheldt in Holland. The editor of the *Monthly Journal of Pharmacy*, who has been engaged in observations on sunflowers, found that during the month of June, 1885, a quarter of an acre of sunflowers exhaled, with a mean temperature of 70° F. at midday, exactly 1950 gallons of water in the form of vapour, or sixty-five gallons a day. He attributes the antimalarial action of the sunflower therefore not only to its properties of absorbing and destroying the malarial miasm and of emitting an abundance of pure oxygen, as taught by other writers, but also to its great capacity, owing to its rapid and vigorous vegetation, of absorbing and utilising the moisture of the soil in districts which are unfit for human habitation. He likewise suggests that the aromatic odour of the flowers may perhaps be possessed of antiseptic virtues.

Diploma.—Our correspondent should address a complaint to the registrar, and failing to get satisfaction, to the Registrar-General; also to the Apothecaries' Company. The Medical Council also should receive a statement of the facts, though its power to interfere is less than that of the other authorities. We do not understand our correspondent to imply that certificates of vaccination are accepted.

A.M.D.—We have no recollection of the reference mentioned.

DANGERS OF SWING-BOATS.

To the Editors of THE LANCET.

SIRS,—The following case is another instance—if further evidence were necessary—of the danger of swing-boats when not properly guarded in places of public amusement.

A young woman, whilst watching a show, came unconsciously too near to one of these stands, and on turning round received a blow in the face from one of the boats in its ascent. She was knocked down and much bruised, and both her upper central incisors were dislocated from the maxilla, one being transversely fractured at the centre of the crown. Their attachment to the gum was fortunately undisturbed. With traction and a little manipulation the teeth were both returned to their sockets, and became firmly fixed eventually. Still, the loss of a front tooth is a matter of considerable moment to a woman, and the results might easily have been worse, as we have seen before.

I am, Sirs, faithfully yours,

Skipton-in-Craven, July 17th, 1887. C. W. SESSIONS BARRETT, M.B.

AN INDIAN REMEDY FOR TAPEWORM.

To the Editors of THE LANCET.

SIRS,—In reply to a correspondent's letter in your valuable columns of May 28th last, asking for a remedy for the cure of tænia solium in a case in which male fern, kousso, and pelletierin had each and all been tried unsuccessfully, may I suggest to him to try the powdered seeds of *Embelia ribes*, called by the natives, "bao-birang." If your correspondent is unable to procure these seeds from any druggist in London, and will place himself in communication with me, I will very gladly put him in the way of getting any quantity of them. I have used this drug for the past four or five years in cases of tapeworm amongst Europeans and natives with good results, and it is a favourite Indian remedy in this disease. I have usually given from one to four drachms (or even more) of the powdered seeds with milk or with curds early in the morning, fasting, following it up some hours later with a purgative dose of castor oil. This latter I have found nearly invariably necessary, as the seeds themselves are not purgative. The seeds are about the size and shape of pimento seeds, and are not unpleasant to take, being slightly aromatic in taste. The dose which is efficacious is, I admit, unpleasantly large, and possibly if the active principle could be isolated it could be given in a much smaller dose, and more palatably. I have asked Dr. Warden, the Chemical Examiner in Calcutta, to try to isolate this active principle. Dimmock, in his recent work on the Materia Medica of Western India, mentions that the seeds of the *Embelia ribes* are largely imported into Germany, and form the chief ingredient in several patent medicines for tapeworm. I can vouch for the efficacy of this remedy when given in full doses, repeated every morning if necessary, and I have never seen the slightest ill effects follow its use. The general price of the seeds is about sixpence for 2 lb. Will "Puzzled" give this simple remedy a trial?

I am, Sirs, yours faithfully,

Simla, June 24th, 1887. GEO. H. HABERN, L.R.C.P.Lond., M.R.C.S.

Mr. James S. Hörifall.—We should recommend our correspondent to make application to the Secretary of the St. John Ambulance Association, St. John's Gate, Clerkenwell.

G. M. Ross should address the editor of the paper in which the extract appeared.

Dr. Dudley Buxton.—The paper is marked for early insertion.

PUNCTURE OF THE ABDOMEN.

To the Editors of THE LANCET.

SIRS,—The following case may be of interest in connexion with Dr. Ogle's article on Relieving Tympanites by Puncture of the Abdomen.

Some few years ago, when practising in Gloucestershire, I attended a case of occlusion of the bowels, which continued unrelieved for ten or twelve days. There was much pain, stercoraceous vomiting, and great distension, causing difficulty of breathing, syncope, &c. Finding matters going from bad to worse, and having failed in all other kinds of treatment, I, with the consent of the patient's relatives, punctured the abdomen with a small-sized trocar and cannula in two different places, where the bulging was most prominent, allowing the escape of a quantity of very fetid gas. This operation was followed by immediate relief of all the distressing symptoms, and in the course of three or four days the bowels acted, and the patient recovered. I was induced to try the operation for two reasons, the first being that I had read Trousseau on this subject, who states that punctures of the abdomen in such cases are likely to be productive of benefit, and that they are neither very painful nor dangerous; the second was that I had seen similar treatment adopted in the case of cattle suffering from distension from over-eating with satisfactory results. I think I should always consider myself justified in acting similarly in other cases, having failed in the usual forms of treatment.

I am, Sir, your obedient servant,

Stroud Green, N., July 15th, 1887. HUGH G. WEBB, L.K.Q.C.P., &c.

REGISTRATION OF FOREIGN DEGREES.

To the Editors of THE LANCET.

SIRS,—Permit me to call attention to the cool manner in which the Medical Council performs its duties. By the new Medical Act it is lawful for certain foreign graduates to register their degrees, and the day fixed by Parliament for doing so was June 30th at latest. I sent my degree up to the registrar, with a request that it should be registered on June 30th, and I have had no notice taken of it so far; and now I hear that the Executive Committee is called for July 25th to consider the matter. Had I been registered at the proper time, I should in all probability have been elected to an important office, for which a registered M.D. is a *sine quâ non*. It is now filled up, and I am still unregistered.

I am, Sirs, yours truly,

July, 1887. M.D.

*** Our correspondent's case seems hard, though he does not give us particulars of his other qualifications, if any. But the law does not contemplate a hasty or wholesale registration of foreign degrees, but a careful consideration of the case of each university. Even under Clause 16, providing for the description of foreign and colonial titles to be added to the names of already registered practitioners, the Council has to be satisfied that the degree has been obtained after proper examination, and before the passing of the Act—conditions that require a little time.—ED. L.

UNQUALIFIED ASSISTANTS.

To the Editors of THE LANCET.

SIRS,—Though a great many letters have already appeared on the above subject, I trust you will insert this, as our position daily becomes more serious, and it behoves us to do something in our own behalf. The vital question now is, What is to become of us? Are we to starve, if the law and the medical profession itself make it impossible to obtain employment, as now seems almost the case? By our previous training we are totally unfitted for anything else. Business men can obtain *employés* ingrafted from boyhood with business, who are for this reason of far greater value than one without experience, however well educated. Chemists, if we are willing, will not employ us without previous apprenticeship, which closes their portals to us. There is no denying the hardships of those who, like myself, besides often being the sons of medical men, have matriculated at a university, and entered as *bonâ fide* students, when, after undergoing half or more of the curriculum and passing some of their examinations, they have through pure misfortune to break off and go as assistants. My testimonials will prove that my hospital work and several years' experience in large general practices, together with hard reading at the same time, have made me competent to obtain a livelihood in some defined medical capacity. Can you, Sirs, suggest any plan for our benefit? And I also appeal to the members of the profession to aid us, who, had fate been propitious, would long ago have been numbered in their rolls. I have no doubt all would be willing to undergo a fair test, so that we could, as has been before suggested, be registered as assistants. We are, unfortunately, heavily handicapped by the large number of newly qualified hospital men constantly being added to the number of competitors for a livelihood in medicine, but who—and it is the expression of medical men themselves—are our inferiors as far as private practice is concerned. Apologising for occupying so much space,

I am, Sirs, yours sincerely,

July, 1887. AN UNQUALIFIED ASSISTANT.

Edwardsonist (Brighton).—1. The competing claims of literature and science in the mental equipment of youth were quite well known in the first century.—2. The passage is from Petronius Arbiter I. (ed. Bücheler): "I am of opinion that our boys at school are made very unintelligent, because they neither hear nor see any of those things which are in practical use" (Ego adulescentulos existimo in scholis stultissimos fieri, quia nihil ex his quae in usu habemus aut audiunt aut vident).

A. B. C. would no doubt obtain the information he desires by application to the Secretary of the Brussels Medical Graduates' Association, Dr. Pocock, The Limes, St. Mark's-road, N. Kensington.

Young Diabetic.—We do not prescribe.

"REMOVAL OF BREAST TUMOUR WITH THE AID OF COCAINE."

To the Editors of THE LANCET.

SIRS,—In your issue of June 18th I find a very interesting report of removal of adenoma of the breast with cocaine as the anæsthetic. Inasmuch as Mr. Grün used very strong solutions of the drug, and also believed it to be the first case of removal of a tumour of the breast under the influence of cocaine, I beg leave to call your attention to a case of amputation of the breast under cocaine published in the *New York Medical Record* of June 4th, 1887. The operation was performed in the New York Skin and Cancer Hospital on March 27th, the patient being seventy-eight years of age, and having a double cardiac murmur. In other words, ether was positively contra-indicated by the condition of the patient. The anæsthetic was confined to the region of operation by the use of a large rubber ring, as devised by Dr. F. L. Corning of this city. A two per cent. solution of cocaine was then injected into the skin along the entire line of incision, which I first traced with tincture of iodine. Then the base of the tumour was flooded with the same solution. The operation was painless and exceedingly satisfactory. It might be well to state that only three drachms of this two per cent. solution were used, the operation lasting twenty-five minutes. When presenting the case to the Surgical Section of the New York Academy I expressed the opinion that some modification of Dr. Corning's device would enable us to remove such tumours, even after they have invaded the axilla, in cases where general anæsthesia is inadmissible.

I am, Sirs, yours very truly,

New York, July 7th, 1887. DANIEL LEWIS.

Rev. Robert Sorsbie.—There is no recommendation of the system to be found in THE LANCET of the date given. The passage may have been extracted from an advertisement.

Cavendo tutus.—We are not aware of the existence of any book of the character mentioned.

Inquirens and *Truthful James* have not enclosed their cards.

HAY FEVER: CORRIGENDA.

To the Editors of THE LANCET.

SIRS,—In my letter published in your last issue may I ask that *gastro-intestinal* may be read for "gastric intestinal," and *inflection*, or possibly more correctly *deflection*, for "infliction."

I am, Sirs, yours faithfully,

July 18th, 1887. J. PERCIVAL HUNT.

The Publisher cannot hold himself responsible for the return of testimonials, &c., sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

Clinical Lecture
ON THE
THERAPEUTICS OF HEART DISEASE.

By THOS. OLIVER, M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE INFIRMARY, AND LECTURER ON PRACTICAL PHYSIOLOGY AT THE UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, NEWCASTLE-UPON-TYNE.

[AFTER dealing with the nervous mechanism of the heart, and the relationship of the beats of that organ to varying degrees of arterial tension, the lecturer proceeded with the following remarks on cardiac therapeutics.]

In the treatment of most of the forms of cardiac disease rest in bed is more or less a necessity; and yet rest in the recumbent position has perhaps, in this country at least, been too much insisted upon, for excellent results have been obtained abroad by Oertel and others by means of Alpine climbing, graduated gymnastic exercises, and massage. The experience of physicians in this country who have given this method of treatment a trial is favourable, due care being taken as to the selection of cases. Where the walls of the heart are extremely feeble, we do well, in the first instance at least, to reduce the strain which is thrown upon them, and so we keep the patient quietly in bed for a few days that he may be carefully watched. Called urgently to a case of old-standing heart disease, with feeble pulse and difficult breathing, and with secondary lesions in lungs, liver, and kidneys, you would at once lose no time in administering such stimulants as brandy, ammonia, or ether; but where time is given for a careful line of treatment to be adopted, you would naturally direct your attention to a list of drugs whose efficacy in restoring disordered states of the heart and circulation is known to you either practically or theoretically. It is to this class of drugs that the term "cardiac tonics" has been applied—tonics in the sense that they act slowly and improve the contraction of muscular fibre, rendering in the case of the heart the beat of that organ slower and more powerful. Pushed beyond this limit, however, they frequently tend to bring about disordered and irregular cardiac movements; hence the necessity for care as to their employment, and watchfulness as to the effects produced by them. Whenever therefore the propelling power of the heart is failing, these are the drugs that are called for.

Now, everything which tends to keep the blood in the heart, or behind it in the veins, is simply so much obstruction placed in the way of the circulation. Obstruction at the aorta, or at any of the valvular orifices of the heart, is an impediment to the circulation, to overcome the effects of which the heart or some of its chambers must hypertrophy. Regurgitation through any of the cardiac orifices acts almost exactly in the same way. It is an obstruction, for it delays the circulation and tends to rob the arteries of blood. And the drug which has for us the greatest interest is *digitalis*. In aortic obstruction, hypertrophy of the left ventricle is generally present to such an extent that, the driving power of the heart being thus increased behind the obstruction, sufficient blood is squeezed through the constricted orifice during systole, so that no medicinal interference is, as a rule, called for. And the same remark applies to many cases of mitral stenosis—the hypertrophied left auricle is quite sufficient to fill the left ventricle with blood, owing to the contraction of the auricle taking place during the longer of the two periods of the cardiac cycle. It is the failure of a compensation that has already existed, or when compensation fails to be developed, that causes the subject with cardiac disease to come to us for advice. In many of these digitalis acts well; but as these are the cases in which a dilated right ventricle is sooner or later developed, and with this hepatic fulness and gastric catarrh, the drug has frequently to be discontinued on account of the sickness which is present. The cases, in my opinion, in which digitalis acts satisfactorily are those of mitral regurgitation where the lesion has not been too long in existence, where slight dilatation of the left ventricle is present. In these, owing to the improvement in the tone of the muscular walls of the ventricle, not only is there a larger quantity of blood sent forward into the system under a higher pressure, but by the drug increasing in addition the contractility of the circular muscular fibres which surround the mitral orifice, mitral regurgitation is itself diminished, a smaller quantity of blood is driven backwards towards the lungs, pulmonary congestion is lessened, and the pressure on the right side of the heart is diminished. It is in regard to the employment of digitalis in aortic regurgitation that the greatest difference of opinion prevails. Contrary to the opinion of many writers, I regard digitalis as of the greatest service in the treatment of aortic reflux. But there are cases and cases of aortic regurgitation. This is the form of cardiac disease in which, while there is often great effort on the part of the heart, very low arterial tension is nearly always present. I have seen a few cases of aortic regurgitation with high tension pulse, and they have always struck me as being not only the cases most likely to have the greatest longevity, but as being those in which fewest cardiac symptoms are complained of. A patient who has gone about for twenty years with aortic regurgitation, and with well-filled arteries and pulse of good tension, is in a very different condition from one whose arteries are seen pulsating visibly, whose pulse is of low tension, and whose countenance is pale. The former, even after the lapse of these many years, may require no treatment at all; the other may be practically beyond the influence of all drugs. Still, I must confess that I do not share in the opinion that the use of digitalis is dangerous in aortic regurgitation. In the early stages of an ordinary rheumatic endocarditis involving the aortic cusps, the diseased condition develops as a rule slowly, and consequently aortic regurgitation takes place only to the slightest extent. When the regurgitation increases, owing to further shrinking of the newly formed tissue in the valves, the heart, under the stimulating influence of the slightly increased distending force, undergoes hypertrophy, its beats become a little more frequent, and thus there is restored to the systemic circulation *in time* what was robbed from it *in quantity* by regurgitation through the aortic orifice. It is at this stage of the disease that most cardiographers consider only one tendency is developed, and that is in the direction of dilatation of the left ventricle. Owing to the refluent column of blood from the aorta passing into the left ventricle during diastole, and coming into contact with that which is passing forwards from the left auricle, the cavity of the ventricle is thus said to be increased; dilatation occurs, but this is kept within limits by the walls of the ventricle undergoing hypertrophy. As in aortic regurgitation the refluent column of blood is regarded as the dilating force, anything therefore which tends to prolong the period of regurgitation not only increases the tendency to syncope by lowering the arterial tension and robbing the capillaries of blood, but tends also to produce over-distension or dilatation of the left ventricle, and the cardiac muscle, thus unable to contract in the face of this over-distending force, remains in a state of flaccidity or paralysis, and death in such might be the immediate consequence. These are regarded as the dangers or risks that attend the administration of digitalis in aortic regurgitation—dangers that may be diminished by keeping the patient in the recumbent position. It has always struck me as being strange that if the upright or semi-upright position is the one in which the refluent column of blood through the aortic orifice exerts the greatest degree of pressure within the left ventricle—pressure spoken of as dangerous,—why is it that patients who are the subjects of this affection so unhesitatingly, and frequently contrary to our advice, assume this position? I do not believe in the dangers of this distending force in the early stages of aortic regurgitation from disease of the valves if the nutrition of the heart is maintained. There is a tendency to dilatation, but any attempt to make the distension permanent at this stage is met by increased contractility and hyperplasia of muscular fibre. Only a fortnight ago I made a post-mortem examination on a case of old-standing aortic regurgitation, and I found the walls of the left ventricle nearly an inch thick, whilst the cavity could not be said to be above the normal. Nor do I believe that by lengthening the period of diastole you allow greater reflux to take place into the left ventricle, and thus tend to the production of those dangerous conditions to which I have alluded. My experience of the treatment of aortic regurgitation is that here, just as in other forms of cardiac

Digitized by Google

disease, your patient is likely to do well the nearer you can bring the beats of his heart to the normal. The cases of long-standing aortic regurgitation—twenty years and upwards—that I have seen are those in which the pulse ratio is low, whether they have been taking medicine to keep it thus or not; and I know of a few cases at the present time where to my knowledge the disease has lasted from seven to ten years, and the pulse is frequently as low as 44 per minute, without there ever having been the least feeling of syncope—the patients following their handicraft the while. Instead of regarding the prolongation of the period of pause in the heart as dangerous, and giving time for the left ventricle to be over-distended, what occurs is this: Admitting that the number of beats of the heart has been reduced by digitalis, then such slowing is not only accompanied by improvement in the contraction of cardiac muscular fibre, but also by increased arterial tension, which means not only that the capillaries generally are better supplied with blood, but that the coronary arteries, too, are better supplied, and consequently that the heart is better nourished. But I also think that under these circumstances the regurgitation is itself lessened, and for this reason the aortic orifice is more or less constricted by the contraction of its own circular muscular fibres, or if not to any great extent by them, by the prolongation of that period which is spoken of by Foster as the third phase in the systole of the left ventricle. The contraction of the left ventricle still continues after all the blood has been ejected from it, and if this period is lengthened the orifice of the aorta still remains constricted, and the easy escape of blood backwards into the left ventricle from the aorta is prevented. While I cannot recall one case in which digitalis could be regarded as precipitating the fatal issue in aortic regurgitation, I can recall very many which have experienced the greatest benefit from it. The drug has frequently disagreed and aggravated at times existing gastric symptoms, but this applies to all cardiac remedies. Wherever I have had satisfactory results, they have always come along the line I have already mentioned—viz., slowing of the heart's beat, increase of arterial tension and improvement of cardiac nutrition. But aortic regurgitation is generally associated with mitral regurgitation, and as we have seen in dealing with mitral regurgitation the action of digitalis is to narrow that orifice and thereby diminish reflux through it, so in these combined cases the mitral ostium is also narrowed, and thus owing to lessened regurgitation through it, an additional factor is brought into operation, whereby the arterial tension is raised. In all cardiac cases it is the sudden assumption of the upright position which is dangerous, and not simply the fact that it has been assumed. The ill effects which I have seen follow the employment of digitalis have been more upon the stomach than the heart, but as digitalis is a drug which raises arterial tension by causing contraction of the peripheral arterioles, and thus throws additional weight upon the heart, I would not use it in cases where I suspected fatty heart or extreme dilatation of the left ventricle, nor would I consider its employment called for in any case of cardiac disease, no matter the lesion, in which arterial tension was already high.

In *convallaria* we have an excellent substitute for digitalis in the treatment of many cases of aortic regurgitation. My best results from this drug have been obtained in aortic regurgitation, and next to that in mitral stenosis. In cases of aortic combined with mitral regurgitation I have frequently found it relieve, and that very quickly too, urgent dyspnœa over which digitalis had no effect. I am inclined to think that it acts purely as a cardiac tonic—i.e., directly upon the heart, by improving the tone of its muscular fibre. It is not a drug that, as a rule, is badly borne or causes gastric irritation, but in one of my cases of advanced mitral regurgitation its administration was always followed by sickness and vomiting.

Of *casca* I have had no experience.

Belladonna I look upon as a valuable drug in the treatment of heart disease. Whilst it diminishes the sensibility of the endocardium to the varying pressure exerted by the distending column of blood on the walls of the heart, thus lessening the sense of fluttering and palpitation, it has induced easier and more forcible beats of the heart, partly by improving the tone of the organ, and probably too by its somewhat dilating effect upon the bloodvessels. In cases of mitral regurgitation its efficacy is most marked. Many of my best results have been obtained from belladonna in cases, chiefly mitral, where digitalis and other drugs caused violent sickness. Belladonna in such not only gives relief to the difficulty of breathing, but relieves the gastric irritability as well.

From *caffeine* I have had good results, particularly in the treatment of mitral stenosis. I frequently combine it with convallaria, and have soon found arterial tension raised and diuresis increased. In only two of the several cases of mitral stenosis with dilated right ventricle in which I have employed it have I been obliged to discontinue it on account of sickness.

Through the kindness of Messrs. Christy of London I have had some experience of the beneficial effects of *Kola paste* in the treatment of heart disease. It is supplied in large irregular masses of a brown colour, not unlike chocolate, and is a paste into which the juice and substance of the Kola nut largely enter. Its efficacy as a nervine tonic has long been recognised in those places where the fruit abounds. By the inhabitants of such it is employed as an antidote to alcohol: men who are so intoxicated and rendered incapable of walking straight are said to become sober and recover their normal gait from within half an hour to an hour after taking the drug. To patients who are the subjects of heart disease I often give as a beverage for breakfast two drachms of the Kola paste mixed well with boiling water, sweetened with sugar, and either flavoured or not with vanilla; and from a repetition of this night and morning not only has there been increased diuresis (a fact explained by the 2 per cent. of caffeine which it contains), but good has also come from its action as a cardiac tonic and nutritive. Cases of mitral regurgitation have received much benefit from it, and some of my patients, the subjects of aortic regurgitation, have received so much good from it that they ask for its continuance, telling me at the same time that whilst taking it they pass a larger quantity of urine, and feel generally more comfortable. Dropsy I have seen disappear under its use. In the treatment of the headache complained of occasionally by patients the subjects of cardiac disease consequent upon contracted kidney and diseased arteries, I have had satisfactory results from its use.

Next to digitalis—nay in many respects superior to it, I rank *strophanthus* as a cardiac tonic. Strophanthus is one of the most powerful cardiac tonics we possess. A few doses of the tincture are in many cases sufficient to produce in patients who are the subjects of aortic or mitral regurgitation a feeling of well-being and comfort, followed by complete relief to difficulty of breathing. In functional cardiac irregularity its effects are quick and lasting, while in many cases of advanced mitral regurgitation the difficulty of breathing is soon relieved, the pulse improved, and the quantity of urine increased. Similar results have been obtained in the treatment of aortic regurgitation. Patients unhesitatingly speak of the relief which is given to any præcordial pain that is present, of diminution of, or relief to, the numbness felt running down the left arm, of relief to dyspnœa, and of it creating a feeling of general well-being consequent upon the improved state of their circulation. Through the kindness of Messrs. Brady and Martin, of Newcastle-on-Tyne, I have tested the therapeutical values of ethereal tinctures made from the pericarp, hairs, and seeds of the plant. From the tincture made from the pericarp no decisive results were obtained, although one patient, the subject of aortic regurgitation who could not take convallaria without feeling sick, said that when the dose was pushed it relieved præcordial pain. It did not increase the amount of urine passed. The tincture made from the hairs—which in colour is not unlike that made from the seeds, a beautiful green—answered well. Its efficacy is less marked than that made from the seeds. It is not nearly such a strong diuretic. From my experience of the tincture made from the seeds, I regard strophanthus as a powerful cardiac drug; it acts quickly and strongly upon cardiac muscular fibre in small doses, but in large doses it is a cardiac irritant and muscular poison. Whatever improvement follows its administration is, I am convinced, from its special action upon the heart; more forcible contraction of that organ is induced, the general arterial tension is thereby raised, and diuresis is promoted. Old-standing cases of mitral regurgitation, with small feeble pulse, cold extremities, distended jugulars, and pulsating liver, have improved under its use; and yet, while this is the case, it is only right to mention that in not a few patients most unpleasant symptoms have been developed, such as sickness and vomiting, pain in the stomach, and diarrhœa—symptoms which,

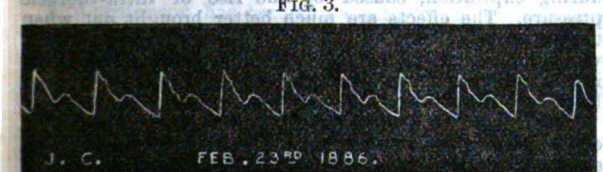
Digitized by Google

while they have in many disappeared on reducing the dose of the drug, have in others only yielded on withdrawing the drug altogether. Its taste is somewhat objectionable, being extremely bitter. Three minims of the ordinary ethereal tincture is quite a sufficient, and to many rather a large, dose. As an illustration of the good effects of strophanthus I would point to the subjoined sphygmograms. (See Figs. 1 and 2.) In this case the effect of the drug was most

FIG. 1.

Deeply cyanosed; pulse feeble and rapid; ineffectual systole; mitral regurgitation; dilated left ventricle. Taken before treatment, when mitral murmur was not very audible.

FIG. 2.



One week after taking strophanthus: much improved; pulse stronger and firmer; less ineffectual systole; mitral systolic murmur much more audible.

marked, and the case is typically one of those in which its influence is soon felt by the patient. Here, in addition to the mitral regurgitation and dilated left ventricle, there was much cardiac distress, shortness of breath, and ineffectual systole; several of the pulses failed to reach the wrist. A few doses sufficed to dispel the unpleasant cardiac symptoms, and restored the radial pulse to a very great extent. In cases, too, of functional cardiac derangement, palpitation, sense of fluttering, and enfeebled cardiac action, strophanthus has, in small doses combined with stimulants, answered well.

In *sulphate of sparteine* we have a drug (dose one to three grains) of whose beneficial effects as a cardiac tonic I can speak highly. Probably its action as such is indirect. In one of my cases of aortic and mitral regurgitation ascites developed, due perhaps to some subacutely inflamed condition of the peritoneum as much as to the state of the heart. The distension of the abdomen was so great that the breathing became much impeded by interference with the descent of the diaphragm. The action of the heart was much embarrassed. The patient was very ill. His pulse was soft water-hammer, and 110 to the minute. A few days after the administration of sparteine the distension of the abdomen was considerably less. The pulse was of much firmer tension, and had fallen to 68, and the breathing had become easy. From the sphygmograms (see Figs. 3, 4, and 5)

FIG. 3.

Sphygmogram taken when first under treatment for aortic and mitral regurgitation. Pulse of low tension.

FIG. 4.

Taken on readmission six months after the above, when the abdomen was filled with fluid, and there was œdema of feet, with pulse extremely rapid and of low tension. Tracing taken before treatment.

FIG. 5.

Taken a few days after the preceding, when he had received considerable benefit from sparteine and digitalis; ascites disappearing; large quantities of urine being passed. Pulse had fallen from 110 to 68 beats per minute; tension much increased coincident with improvement in health. No albumen in urine.

it will be observed that the tension had considerably risen, and that it bears some resemblance to the tracing taken in Bright's disease. Corresponding with the rise in the arterial tension and that of feeling generally better, the amount of urine passed rose from twenty to ninety ounces daily, and in less than a fortnight not only had the whole of the ascites disappeared, but the ordinary cardiac symptoms depending upon the aortic regurgitation had also ceased to trouble him; this, be it remembered, at a time when his pulse was only 68 per minute, the half of what it was on admission, when the period of cardiac diastole was so lengthened that in accordance with the usually accepted opinion the effect of aortic regurgitation should have been at its worst. In this condition, and with a pulse of high tension, the patient left the infirmary feeling quite well, and returned to his work as a machinist in the Elswick works. I have seen him since from time to time within the last few months, and he tells me that he has felt better since this last illness than he has done for the last six years, the date to which he ascribes the origin of his cardiac affection. His case is not only an illustration of the absence of danger in producing lengthening of the cardiac diastole, but is also a striking one of the good effect which is produced upon the heart and thus, upon the system in general, by slowing the pulse and raising at the same time arterial pressure. Another thing which was noticed in this case was that, while the aortic diastolic murmur was quite easily heard and recognisable before the treatment was commenced, its audibility was much increased—a fact which, while it points to an increase in the force which drove the blood backwards as it had done forwards, may also have been due to increased constriction of the aortic orifice—either stronger contraction of the circular muscular fibres at its orifice, or prolongation of the third phase in the systole of the left ventricle. Sparteine has always seemed to me to act very much in the same way as digitalis—i.e., by causing contraction of the peripheral arterioles. Arterial pressure is thus raised, the coronary arteries are better flushed, cardiac nutrition is improved, and the left ventricle thereby responds with greater vigour and force to the stimulus of distension created by the column of blood within it. Other dropsical effusions quite irrespective of heart disease—e.g., ascites from cirrhosis of the liver, pleural effusions—have disappeared under its use, and in any case of dropsy where the pulse is small and compressible I should regard sparteine as a drug extremely likely to do good.

Barium chloride, I find, raises arterial tension and thus acts as a diuretic. With half-grain doses morning and evening, several of my cases of aortic regurgitation have had their pulse ratio reduced, the pulse rendered fuller and firmer, and the amount of urine increased. Its action as a cardiac tonic is indirect.

Venesection has fallen too much into disuse. In several of my cases, both of aortic and mitral regurgitation, I have not only succeeded in warding off impending death, but by removing blood from the veins have placed the patient in the enjoyment of good health for months to come, repeating from time to time as necessity arose subtraction of blood from the arm. In cases of over-distension of the right ventricle, where the jugular veins are swollen, the face livid, the pulse small, and dyspnœa urgent, I have never hesitated to remove from eight to twelve ounces of blood from the vein in the arm, or failing this from any very distended vein at a reasonable distance from the heart, with, in most cases, almost immediate relief to the breathing, improvement of the pulse, and with increased comfort to the patient. The removal of blood relieves the over-distended right ventricle, wards off the paralytic condition into which its walls are being thrown as the result of over-

Digitized by Google

distension, and, by allowing the muscular fibres to contract upon diminished contents, life has been saved. The use of stimulants at this time must never be forgotten.

Just as venesection as an old remedy in acute nowadays seldom is practised, the same remark applies to the administration of *mercury*. Neither in recent endocarditis, nor in the treatment of the conditions leading up to it, is mercury ever called for; but in cases of old-standing mitral disease, where the venous system generally is engorged, the liver enlarged, and its venous channels over-distended, the employment of pil. hydrarg. c. coloc., in two to four grain doses at bedtime or for a few days at first night and morning, with or without the addition of squill, will be often followed by the happiest results. It will in almost every case form a useful adjunct to any line of treatment which is adopted. Calomel is again being resorted to as a remedy in cardiac dropsy.

In the treatment of angina pectoris nothing has answered so well as the inhalation of a drop or two of *nitrite of amyl*, but in many cases of aortic regurgitation attended by constant and very severe præcordial pain, with paroxysmal exacerbations, I have had the most satisfactory results from the internal administration of nitrite of amyl, beginning with two minims, and increasing it to ten, fifteen, or twenty minims, combined with ten minims of tincture of opium and twenty minims of sal volatile.[1]

In the treatment of the insomnia of heart disease we have two reliable and safe drugs that we can fall back upon. *Paraldehyde*, in doses of from fifteen to thirty grains, answers well. The sleep is similar to that induced by chloral, but, unlike this drug, it does not depress the action of the heart. I have not found it act as a diuretic, as some assert. The only and a most important drawback to it is its very unpleasant taste. Patients simply refuse to take it after a few trials. Not so with *urethan*, which I have found, in doses of ten grains and upwards, to be one of the safest hypnotics in cardiac disease. It is in heart disease that we frequently see patients thoroughly worn out for want of sleep. Nay, they are even afraid to sleep, for no sooner has sleep been induced than, the cyanosis increasing, they suddenly wake up and gasp for breath. Opium and its allies are most unsafe hypnotics where there is such a carbonised state of the blood; they only add to the accumulation of waste products in the blood. Chloral, too, cannot be given without running the risk of inducing cardiac failure. It is in such cases that urethan acts well, and is perfectly safe. It is less unpleasant than paraldehyde; in fact, if there is any marked unpleasant taste with the drug, the probability is that it is of English and not of German make. I have seen a patient, the subject of heart disease, who had not slept for several days, fall into a calm and placid sleep after a few grains of urethan, waken from it calmly four or five hours after without any dyspnœa, and express himself as feeling quite a new man to what he had been a few hours previously. After this the whole character of the case has been changed, and patients who until then had been retrogressing not only began to improve, but ultimately made a good and fairly lasting recovery.

[illegible]

[1] It is only of late that I have had experience of the value of the nitrites in the treatment of mitral stenosis. Dr. Barr, in the *Liverpool Med. Chir. Journal* for July, 1886, draws attention not only to the inefficacy of digitalis, but to the harmfulness of the drug in mitral stenosis. In such cases, while the systemic arteries are under-filled, the vessels of the lung are over-filled, as are also the left auricle and the chambers of the right side of the heart. The left ventricle, compared with these, is practically empty. What is wanted is an increase of force in the right ventricle and a reduction of the contents of the pulmonary vessels. No cardiac tonic will produce this alone without acting upon the left ventricle. If you increase the capacity of the arterial system, relief may come to the over-distended lungs and the veins generally. In one case of mitral stenosis with hæmoptysis, urgent dyspnœa, dilated right heart, and small feeble pulse, the relief given generally by nitrite of amyl was most marked.

[illegible]

A New Hospital at Zanzibar. According to the *Bombay Gazette*, Mr. Tharia Topun made an offer to the British Government, on the day of the celebration in Bombay of Her Majesty's Jubilee in February last, to build and endow a hospital at Zanzibar. The estimated cost of building the hospital will be about 80,000 rupees, and Mr. Tharia Topun has offered a further sum of 50,000 rupees for maintaining the institution on a permanent basis, which amount the British Government will hold in trust for the donor. The institution will be named the Tharia Topun Hospital. The offer has been accepted by Lord Salisbury, as Foreign Minister, on behalf of Her Majesty's Government.

EFFECT OF RESPIRATION AND DEGLUTITION ON THE VENOUS HUM.

By GEORGE R. MURRAY, B.A. CANTAB.

THE venous hum, as heard in the large veins of the neck, is a murmur which gave rise to much discussion as to its situation when Bouillaud first drew attention to it. He named it "bruit de diable," and considered that it was an arterial murmur, an opinion which was also held by other French writers. It was first shown to be a venous murmur by Dr. Ogier Ward in this country. This murmur has been found to be of little practical value in diagnosis, and consequently attracts much less attention now than it did formerly.

The venous hum is most distinctly heard on auscultation over the lower end of the right internal jugular vein, in the neck of a patient suffering from anæmia; and when studied in this situation it illustrates some points which are perhaps of physiological rather than medical interest. As it occurs in a vein just outside the thorax, this murmur is exposed to influences which cannot be brought to bear on intra-thoracic murmurs. Thus we find marked changes in the venous hum are brought about by respiration and deglutition. Before proceeding to the consideration of these changes, it is necessary to review briefly the conditions which produce the venous hum.

The internal jugular vein is slightly dilated at its lower end into a kind of sinus, which is so attached by the cervical fascia to the surrounding structures that it cannot shrink. When the volume of the blood is diminished in anæmia the upper part of the vein shrinks, but its lower part retains its former size. The blood flowing from the narrowed vein above into the relatively dilated part below sets up a fluid vein, and as the blood contains fewer red corpuscles than it does normally, it is the more readily thrown into vibrations. It is now generally supposed that the vibrations of the fluid vein produce the murmur, and in some cases a fine thrill can be felt. It is important to bear in mind that the loudness of a murmur so produced varies with the rate of the flow. The faster the flow the louder the murmur, and conversely slowing of the flow diminishes or stops the murmur. Changes in the rate of the blood-flow in the vein may be brought about by variations in either internal or external pressure. The former is illustrated by respiration, and from some observations which I have made, the latter appears to be illustrated by deglutition.

With regard to respiration.—In some cases slight variations in the venous hum can be heard during normal breathing, the murmur being louder during inspiration than during expiration. If, however, the patient makes an inspiratory effort with the mouth and nose closed, a distinct increase in the loudness of the murmur can be heard; and conversely a slight expiratory effort, made in the same way, stops the murmur. These facts are practical illustrations of the two effects of respiration on the blood-flow in the veins towards the heart: first, the increase in the rate of the blood-flow, due to the diminished intra-thoracic pressure during inspiration; second, the slowing of the blood-flow during expiration, caused by the rise of intra-thoracic pressure. The effects are much better brought out when [illegible] of the air is prevented, so that the whole force of the inspiratory or [illegible] into play is expended in aiding or retarding the flow of blood into the thorax.

With regard to deglutition.—I find that [illegible] slowing the venous hum in the [illegible] opinion. This is a fact to which I believe [illegible] before been drawn. It is most conveniently observed in the following manner:—Place the patient in the erect posture, with the head slightly turned to the left, and apply the stethoscope over the lower end of the right internal jugular vein just above the clavicle. Then get the patient to swallow a mouthful of water. The venous hum which was previously heard [illegible] during the act of deglutition, and [illegible] as soon as it is over. I [illegible] a [illegible] possibility of compression of the internal jugular vein by the omo-hyoid muscle was suggested by Thelle. A consideration of the anatomical relations of the omo-hyoid muscle and the internal jugular vein, and of the action of

Digitized by Google

some of the muscles which aid deglutition, will show how this may be brought about.

The posterior belly of the omo-hyoid muscle arises from the upper border of the scapula, just internal to the notch. From this point the muscle runs forwards and inwards across the lower part of the neck, passing behind the sterno-mastoid muscle. It here becomes tendinous, and bends upwards, passing just in front of the internal jugular vein. It then becomes muscular again, and the anterior belly ascends to be inserted into the body of the hyoid bone. The tendinous part of the muscle passes through a process of the deep cervical fascia which is attached to the cartilage of the first rib. This process of fascia maintains the bent position of the muscle, but may allow the tendinous portion to be pulled slightly upwards when the muscle contracts or is put on the stretch; for this muscle acts as a tensor of the cervical fascia. The two ends of the muscle and the central tendon appear so to lie that the line of action of the muscle is in a plane which slopes from above downwards, forwards, and outwards. Consequently, when the muscle contracts or is put on the stretch, the part of it which lies just in front of the internal jugular vein is pulled upwards, backwards, and inwards against the vein, so as to compress it.

Now, in deglutition, we find that the omo-hyoid muscle is first put on the stretch and then contracts. At the end of the first part of deglutition, the hyoid bone is raised by the action of the genio-hyoid, anterior belly of digastric, and mylo-hyoid muscles, the omo-hyoid being thus put on the stretch. Immediately afterwards the omo-hyoid contracts with the other depressors of the hyoid bone, so as to bring the hyoid back into its normal position. Thus it would seem that the cessation of the venous hum is due to the tension and subsequent contraction of the omo-hyoid muscle, compressing the internal jugular vein, and so retarding or arresting the flow of blood as to stop the murmur.

It may be maintained that the omo-hyoid muscle could not thus exert sufficient pressure. Much pressure, however, is not necessary, for the wall of the vein is thin, the blood in the vein is at a low pressure, and the murmur is easily stopped by pressure on the vein, either with the finger or with the stethoscope itself. It may also be here mentioned, in conclusion, that pressure thus exerted on one internal jugular vein causes an increase in the loudness of the murmur in the other, from the increased rate of blood-flow along it, showing how readily one internal jugular vein returns blood from the brain when the flow in the other is obstructed.

Torrington-square, W.C.

A TABULAR STATEMENT OF SIXTY-FOUR CASES OF ABDOMINAL SECTION,

INCLUDING FORTY-FIVE COMPLETED OVARIOTOMIES; WITH REMARKS.[1]

By C. J. CULLINGWORTH, M.D.,

PHYSICIAN TO ST. MARY'S HOSPITAL, MANCHESTER; PROFESSOR OF OBSTETRICS AND GYNÆCOLOGY AT THE OWENS COLLEGE; VICE-PRESIDENT OF THE OBSTETRICAL SOCIETY OF LONDON.

The profession has become so accustomed to long lists of successful operations by leading ovariotomists in this country that it needs some boldness on the part of those of us who have worked in a more limited sphere to publish our results. It has always appeared to me, however, that whoever accepts a hospital appointment undertakes grave responsibilities—not only to the institution he serves, but to the profession of which he is a member; and that not the least of the responsibilities which come under this latter head is that of making public from time to time the results of his hospital experience, and of endeavouring to present them in such a shape as will make them useful to his professional brethren. It is under the influence of this conviction that I publish the accompanying statement of my cases of abdominal section. It was my original intention to give an account of the work of the last three or four years, but it soon became apparent that such a course would make my results appear better than in the aggregate they really are, and I decided that it would be more honest, and probably more instructive, to include in the statement all my cases from the year 1873 (when I first operated) to the present time, a period of fourteen years. It seemed to me that I should thus not only secure myself against the charge of suppressing unfavourable statistics, but furnish myself with a more useful text for discussing the operation and comparing past and present results.

My earliest experiences in abdominal surgery were perhaps even exceptionally disheartening. The first ovarian case that came under my care was that of a woman with a multilocular tumour, sixty-six pounds in weight. The size of the abdomen was enormous. The legs and trunk were œdematous, and the uterus and vagina had been pushed downwards by the tumour until they formed a hernial protrusion outside the vulva. The thoracic viscera were also very considerably displaced. As the gelatinous character of the contents of the tumour rendered quite fruitless an attempt to give the patient relief by tapping, I thought it my duty to try to remove the growth. I succeeded in removing it, but unfortunately my patient died. My next two cases were even more discouraging. In each of them I was unable to complete the operation on account of inseparable adhesions. Both the patients died. During the year that elapsed between these two incomplete ovariotomies, it happened to me to have two cases of extra-uterine fœtation, in both of which abdominal section was required. Again both my patients died; so that my record, after four years, stood thus: five abdominal sections with five deaths. It was a disastrous beginning; but luckily the tide turned, and, during the ten years that have since elapsed, I have had no case of ovariotomy in which I have been unable to complete the operation.

The cases that form the basis of this communication are arranged in two tables. Table I. consists of all my completed ovariotomies, arranged in two series,—the first series extending over the seven years from 1873 to 1879 inclusive, the second series embracing a similar period from 1880 to the close of 1886. Table II. consists of all my cases of abdominal section (to December, 1886) not included in Table I. They necessarily form a somewhat miscellaneous collection. I shall have a few words to say about them presently. In the meantime I wish to draw attention to one or two points of interest in the first table.

The total number of completed ovariotomies is forty-five; of this number, eight are included in the first series and thirty-seven in the second. Of the eight cases operated upon before 1880 four died, giving a mortality of 50 per cent. Of the thirty-seven cases operated upon during the last seven years five died, giving a mortality of 13·5 per cent. If the later cases of this series be compared with the earlier, the improvement is still more striking. All the deaths occurred amongst the first seventeen cases; of the last twenty (covering a period of three years) every one recovered. Side by side with this reduction in the mortality, it is to be observed that the progress of the successful cases towards recovery has become more rapid, more even, and generally more satisfactory. It has come to be quite exceptional for a case to cause even a single day's anxiety; and troublesome complications, such as suppuration along the suture tracks of the abdominal wound, which used to be common enough, have become the rarest possible events.

How is this improvement to be accounted for? It cannot be due entirely to chance, although that is an element which one should not altogether overlook. Nor is it that the more recent cases have all been particularly simple and uncomplicated. Take, for example, the last three on the list. In each of them, as the table shows, there were complications of a very marked kind; in two instances there were serious adhesions, in the other there was no proper pedicle. Notwithstanding which, the patients did exceedingly well, the temperature during the first fortnight being, with scarcely an exception, below 100° F. What, then, *are* the causes of the diminished mortality and the lessened frequency of interruptions to normal convalescence?

Foremost amongst these causes must, I think, undoubtedly be ranked the improvements introduced from time to time in the method of operating. Most of the cases recorded in the first series were operated upon at a time when the most experienced ovariotomists advocated the use of the clamp in the treatment of the pedicle. The reintroduction of the intraperitoneal method of dealing with the pedicle was an immense improvement, and its adoption had a most favourable influence on the statistics of the operation. Almost simultaneously with this advance came the general recognition of the value of antiseptic precautions in surgery. The mortality after operations had hitherto been chiefly due to septicæmia. Prof. Lister taught us by his researches and example that

TABLE I.—COMPLETED OVARIOTOMIES IN HOSPITAL AND PRIVATE PRACTICE.

SERIES I., 1873 TO 1879

No.	Name.	Age.	Civil cond.	Date of operation.	Nature and weight of tumour.	Adhesions.	Antiseptic.	Treatment of pedicle.	Condition of other ovary.	Result.	Remarks.
	A. H.	45	W.	1873. Oct. 17	Enormous multilocular cystoma with thin walls and thick gelatinous contents, pushing up liver to 3rd rib, and causing protrusion from vulva of uterus and vagina; weight, 66lb.	Very numerous	None	Returned	Not recorded	Death in 32 hours	Autopsy disclosed recent peritonitis over whole of lower part of abdomen, glueing intestines together.
2	S. B.	46	M.	1877. July 27	Single cyst left ovary, with solid mass in ant. wall; weight, 11lb. 2oz.	None	None	Clamp (removed Aug. 2)	Not recorded	R.	—
3	F. S.	20	S.	Sept. 12	Large piliferous cyst of right ovary with solid masses in cyst wall, and some smaller cysts grouped around them; 9lb. 6oz.	Slight parietal	None	Clamp (removed Sept. 16)	Not recorded	R.	Had been tapped three times previous to operation.
4	M.A.R.	22	S.	Oct. 31	Compound cyst left ovary, consisting of a mass of small cysts with thick walls interspersed with much solid matter; 8½lb.	Slight omental	None	Clamp	Right ovary size of walnut, cystic; removed	Death in 34 hours	Septicæmia. Pulse and temp. gradually rose from time of operation, until at 9 A.M. on the following day the pulse was 178, the temp. in recto 105·4°; at 5 P.M., temp. 106·9°; at 6, 107·0°; at 7, 107·2°; and at 8.20 (5 minutes after death), 106°.—*Autopsy:* Heart universally adherent to pericard. from old inflammation; right lung cong., lower lobe dark red, solid, friable. Recent perit. in neighbourhood of pedicle.
5	S. B.	24	S.	Nov. 7	Simple cyst of right ovary; 17lb. 2oz.	None	None	Clamp (removed on 11th)	Not recorded	R.	Temp. on 3rd day rose to 103·6°, pulse to 160. Some sloughing of pedicle after removal of clamp; wound open and discharging for nearly 5 weeks.
6	E. F.	27	M.	1878. June 19	One large cyst and many small ones; 14lb. 6oz.	None	Carbolic acid spray and other precautions	Ligatured and returned	Not recorded	R.	Highest temp., 102·2° on 3rd day. Next day 2 drachms of purulent fluid exuded from the wound, which continued to discharge for several days.
7	M. F.	34	M.	Aug. 2	Multilocular ovarian cyst; 10lb. 8oz.	Extensive parietal	Thymol spray	Ligatured and returned	—	Death on 13th day	Maximum temp. on 2nd day, 103·5°; on 3rd day, 102·9°; on 4th and 5th, 101°; on 6th, 101·4°; on 7th, 102·6°; on 8th, 101·2°; on 9th, 103·4°; on 10th, 103·6°; on 11th, 104°; on 12th, 102°; and on day of death, 105·4°. On the 11th day wound was opened and abdomen explored. No pent-up secretion, but intestines matted together from recent perit. No post-mort. permitt.
8	M. D.	38	S.	1879. Dec. 17	Large multiloc. cystic sarcoma; 30lb. 14oz.	Universal	Carbolic acid spray, &c.	Ligatured and returned	—	Death in 26 hours	Patient emaciated and weak; collapse during operation extreme. Death probably due to shock.

SERIES II., 1880 TO 1886 (TREATED ANTISEPTICALLY).

No.	Name.	Age.	Civil cond.	Date of operation	Nature and weight of tumour.	Adhesions.	Drainage, glass tube.	Condition of other ovary.	Result.	Remarks.
9	C. D.	26	M.	1880. March 23	Multilocular cyst of left ovary, 4lb. 14oz.	Omental, intestinal	2 days	Normal	R.	Lower angle of wound reopened, pedicle sloughed, indiarubber drainage tube worn April 8th to 24th. On Aug. 10th the sinus at the lower angle of wound was 1½in. deep. Blood was noticed issuing from wound during 2nd and 6th menstrual periods. In November wound had closed.
10	P. H.	24	S.	July 14	Multilocular cyst of left ovary	None	3 days	Enlarged, cystic: removed. (Had amenorrhœa 16 months before admission.)	R.	August 17th, well and strong; not menstruated.
11	S. S.	43	M.	1881. Jan. 12	Round and spindle-celled sarcoma of right broad ligament, 7lb. 13oz.	Numerous to mesentery	Throughout	Both ovaries normal	D., 69 hours	Septicæmia. Temp. an hour before death, 103·4°; pulse, 150.
12	E. C.	33	M.	April 13	Single cyst, right ovary, 37lb. 8oz.	Slight to omentum	None	Normal	R.	Five months pregnant at time of operation. Aborted April 21st, 9.35 P.M.
*13	M.A.D.	30	M.	Aug. 18. 1882.	Single cyst, right broad ligament, 26lb. 10oz.	Intestinal	None	Cystic (small); removed	R.	—
14	M. K.	26	M.	Jan. 3	Single cyst, 10lb. 2oz.	None	None	Normal	R.	Two months pregnant. Aborted April 20th, after return home; fœtus dead, apparently at 5th month.
15	B. B.	36	M.	Jan. 18	Single cyst, left ovary, 14lb. 12oz.	Parietal	None	Cystic (small); removed	R.	—
16	M. R.	46	M.	Jan. 26	Cystic sarcoma, both ovaries, 51b. and 4lb. 10oz.	Parietal and to each other	36 hours	See under "Nature of Tumour"	R.	Died shortly afterwards from return of disease in peritoneum, &c.

Digitized by Google

17	J. H.	23	S.	March 15	Single cyst, right ovary, 9lb. 2oz.	None	None	Normal	R.	Had been tapped once previous to operation.
18	E. H.	29	M.	May 5	Peritoneal disease, with double ovarian cyst, embedded in friable semi-transp. growth; no pedicle	—	Throughout	See under "Nature of Tumour"	D. next day	Syncope or septicæmia. Had been tapped nine times previous to operation.
19	F. C.	45	S.	May 19	Single cyst, left ovary	Parietal	None	Atrophied and hard; not removed	R.	—
20	M. B.	64	M.	Aug. 23	Cystoma of left broad ligament, 9lb. 1oz.	Parietal, omental	Throughout	Right ovary cystic; removed	D. 8th day	Temp. normal for 24 hours, then gradually rose until evening of 4th day, when it was 100·3°; highest temp. on 5th and 6th day, 101·2°; on 7th day, 101·6°; and on day of death, 100·4°. Death from peritonitis, septic (?) and old mitral disease.
21	M. H.	46	M.	Oct. 11 1883.	Multilocular cyst, right ovary, 19lb. 14oz.	Parietal, numerous	None	Normal	R.	Abscess in abdominal wall burst through wound Oct. 16th.
22	L. B.	28	M.	March 2	Multilocular cyst, left ovary, 12lb. 6oz.	Uterine, omental, intestinal	Throughout	Removed on account of tumour in right broad ligament	D., 38 hours	—
23	S. B.	29	M.	April 18	Single cyst, right ovary, 12lb. 8oz.	None	None	Cystic; removed	R.	Highest temp., 100·2° F.
24	M. S.	20	S.	May 23	Multilocular cyst, left ovary	Parietal, omental, and to right broad ligament	24 hours	Enlarged and indurated; removed	R.	Highest temp., 102°; wound discharged after removal of tube.
25	M. A. K.	46	M.	Sept. 12	Double multilocular cystic sarcoma, peritoneum studded with nodules	Lower tumour adherent to mesentery and post. wall of pelvis	Throughout	See under "Nature of Tumour"	D. 9th day	Peritonitis.
26	M. S.	26	M.	Dec. 12 1884.	Cystic sarcoma of both ovaries	None	None	See under "Nature of Tumour"	R.	Highest temp., 101·6°; after first two days normal. Died April 22nd, 1884, from recurrence of the disease.
*27	M. E. H.	42	S.	Jan. 31	Single cyst left broad ligament, 24lb. 5oz., ovary healthy	None	None	Size of pigeon's egg, cystic; removed	R.	Temp. never exceeded 100° F. Had been tapped 12 times during past 20 years.
28	M. A. D.	51	M.	Oct. 8	Simple cyst, right ovary, 25lb. 7oz.	Parietal, costal, omental	5 days	Atrophied; undisturbed	R.	Much shock; rallied in a few hours. Highest temp. during convalescence, 104·0°, at 2 A.M., Oct. 12. Had been tapped 4 times previous to operation.
29	E. R.	34	S.	Oct. 22 1885.	Multiloc. cystoma, left ovary, 12lb. 3oz.	Parietal	7 days	Cystic, size of hen's egg; removed	R.	—
30	E. M.	16	S.	Jan. 14	Large multilocular cystoma, left ovary, 17lb. 10oz.	None	None	Size of pigeon's egg, cystic; removed	R.	Patient has never menstruated. During convalescence had pelvic hæmatocele, causing dulness and hardness, first on right, afterwards on left, to 4½in. above pubic level. Diagnosis confirmed by aspiration.
31	A. W.	60	W.	Feb. 4	Unilocular, right ovary, 9lb.	None	48 hours	Normal	R.	Had been tapped twice previous to operation. Multilocular cystoma of left ovary removed successfully in May, 1887.
32	S. A. T.	50	M.	March 11	Multilocular cystoma, right ovary, 8¾lb.	None	None	Cystic, size of cricket ball; removed	R.	—
33	A. P.	33	M.	May 29	Multilocular cystoma, 34lb.	Parietal, hepatic, omental	24 hours	Normal	R.	Slow convalescence. Patient much reduced by recurrent peritonitis and recent parturition. Had been tapped once previous to operation.
34	H. F.	57	M.	June 24	Multilocular cystoma, left ovary, 12lb.	Parietal, extensive and firm	48 hours	Dermoid cyst, 3½oz.; removed	R.	Had been tapped six weeks previously.
35	S. A. P.	39	M.	Sept. 9	Multilocular cystoma, right ovary, 7lb.	Parietal and omental	48 hours	Cystic, not much enlarged; removed	R.	—
*36	S. B.	22	S.	Nov. 12	Large thin-walled multilocular cystoma, gelatinous contents; thickened omentum; proliferating masses on peritoneum	Parietal, omental, intestinal	7 days	Cystic; removed	R.	Temp. same evening, 100°; afterwards never above normal. Twelve months afterwards patient well and at work. Exploratory puncture had been made two weeks before operation with no result.
37	E. W.	43	W.	Nov. 25 1886.	Multilocular cystoma, right ovary, 8½lb.	None	None	Normal	R.	—
38	E. C.	40	M.	Feb. 10	Multilocular cystoma, right ovary, 25lb.	Parietal, omental	48 hours	Normal	R.	—
39	M. G.	35	S.	March 17	Multilocular cystoma, left ovary; much solid material; 8lb. 2oz.	None	24 hours	Cystic; removed	R.	Slight suppuration in abdominal wall during convalescence.
40	E. T.	34	M.	Sept. 15	Single cyst, 33lb.	None	None	Normal	R.	Pregnant two months. Patient confined naturally May, 1887.
41	M. A. J.	30	S.	Oct. 6	Single cyst, right broad ligament, 11½lb.	None	48 hours	Cystic, not much enlarged; removed	R.	—
42	B. B.	55	S.	Nov. 10	Single cyst, left broad ligament, 11lb.; small pedunculated sub-peritoneal fibroid of uterus also ligatured and removed	None	None	Atrophied; normal	R.	—
43	M. S.	41	M.	Dec. 1	Cystoma, left ovary; 12lb. 8oz. (fluid, 5 quarts)	Extensive pariet. and omental	96 hours; removed with diffic.; adherent	Normal, but removed on account of closely contiguous cyst of right broad ligament	R.	Temp. during first fortnight uniformly under 100°; afterwards, once exceeded 100° from chill during removal to general ward.
44	A. H.	32	M.	Dec. 15	Thick-walled ovarian cystoma (left), 4lb.; contents, 3 pints of odourless pus	Omental and intestinal, the latter very firm and vascular	24 hours	Normal	R.	Site of adhesion on bowel 1½in. × ¾in., divested of peritoneum, raw and bleeding. Edges of peritoneum at its border stitched together, doubling in and concealing the raw surface, to prevent fresh adhesion. Temp. only once reached 100°, and never exceeded it; from and after morning of 4th day normal.
45	G. H.	48	M.	Dec. 28	Large multilocular cystoma of right ovary and broad ligament; pedicle very short and broad; tied in sections; portions of cysts left in stump. Weight of tumour, 11lb. 13oz.	None	48 hours	Normal	R.	Temp. first six days uniformly under 100°; max. on 7th, 100·2°; on 8th and 9th, 100·6°.

* The cases marked with an asterisk were private operations; the rest were hospital cases.

TABLE II.—ALL THE CASES OF ABDOMINAL SECTION NOT INCLUDED UNDER THE HEAD OF COMPLETED OVARIOTOMIES, 1874-1886.

No.	Name.	Age.	Civil cond.	Date of operation.	Object and nature of operation.	Result.	Remarks.	Reference to detailed account of cases already published.
1	M. P.	32	M.	April 24, 1874	Incomplete ovariotomy.	D.	Tumour very large, multilocular, chiefly solid. Operation abandoned on account of universal adhesions.	—
2	E. D.	36	M.	July 2, 1875	Exploratory incision for supposed suppurating ovarian cyst. Removal of putrid fœtus from an extra-uterine gestation-sac.	D.	Patient suffering from septicæmia at time of operation; died from septic broncho-pneumonia on sixth day after operation.	*Obstetrical Journal of Great Britain*, October, 1875
3	M. B.	26	M.	Nov. 10, 1875	Removal of dead fœtus from extra-uterine gestation-sac.	D.	Patient declined operation until septicæmia had set in. Fæcal fistula in posterior wall of sac. Died 66 hours after operation.	*Obstetrical Journal of Great Britain*, January, 1876
4	A. B.	61	M.	July 5, 1876	Incomplete ovariotomy.	D.	Enormous tumour; operation abandoned on account of intimate connexion with uterus. Died 56 hours after operation.	—
5	E. M.	46	M.	Feb. 7, 1877	Exploratory incision in case of large accumulation of pus between layers of abdominal wall (from rupture of ovarian abscess) simulating ovarian cyst.	D. 7 hours	... ...	THE LANCET, November 3rd, 1877
6	E. McD.	40	M.	Aug. 7, 1878	Nature of tumour doubtful; exploratory incision; uterine myoma; wound closed.	R.	After operation tumour gradually diminished in size, with relief of symptoms and great improvement of general health.	—
7	J. H.	36	S.	June 9, 1882	Nephrectomy for hydronephrosis.	D. 12 hours	... ...	*British Medical Journal*, Nov. 11, 1882, p. 930
8	F. J. H.	45	M.	March 7, 1884	Removal of pedunculated subperitoneal myoma of uterus. Weight 15oz.; pedicle clamped.	D. 3rd day	Septicæmia.	—
9	H. B.	37	S.	Nov. 5, 1884	Nature of tumour doubtful; exploratory incision; uterine myoma; wound closed.	R.	—	—
10	E. B.	30	M.	Jan. 2, 1885	Abdominal section with a view to nephrectomy; pyonephrosis; removal of impacted calculus from right ureter.	D.	Left ureter discovered, at autopsy, also to contain impacted calculus, causing abscesses in left kidney. Death from uræmia (?) 80 hours after operation.	Trans. Path. Soc. of London, vol. 36 for 1884-5, p. 278
11	A. McC.	25	M.	May 13, 1885	Removal of chronically inflamed ovary and small polycystic tumour of each broad ligament.	R.	... ...	*British Medical Journal*, January 30, 1886
12	M. M.	26	M.	Oct. 7, 1885	Small cystic tumour of each ovary with right hæmatosalpinx.	R.	... ...	
13	J. R.	35	M.	Jan. 13, 1886	Exploratory incision for recurrent pelvic peritonitis, with small intra-pelvic tumour; removal of three small broad ligament cysts with right hydrosalpinx. Ovaries not removed.	D.	Died on third day from peritonitis (? septic).	—
14	E. J.	40	S.	Feb. 5, 1886	Removal of uterine appendages for large myoma with excessive hæmorrhage. Both ovaries cystic. Ovaries and tubes removed.	R.	Very slight uterine hæmorrhage for some months after operation, but no flooding. Ten months afterwards myoma much diminished in size, general health very greatly improved.	—
15	E. B.	43	M.	April 14, 1886	Exploratory incision for supposed ovarian cystoma. Removal of large sarcoma of left kidney, which had undergone extensive cystic degeneration.	R.	After patient's return home the disease rapidly recurred, causing tumour over right lower ribs posteriorly, and eventually paraplegia. Died Nov. 26, 1886, seven months after operation.	*Medical Chronicle*, November, 1886
16	M. B.	25	M.	April 30, 1886	Exploratory incision for recurrent pelvic peritonitis, with small fixed intra-pelvic tumour on right of uterus. Right ovary enlarged (3 inches long), cystic; one large cyst filled with pus; universally adherent; removed, with both tubes, which were much thickened, and contained in their walls several cysts.	R.	Drainage tube, 48 hours. Convalescence rapid. Six months after operation, patient stout, well, and free from pain.	—
17	M. H.	45	M.	Oct. 29, 1886	Exploratory incision with view to removal of the uterine appendages, if practicable, for multiple uterine myomata with excessive hæmorrhage and recurrent pelvic peritonitis. Pelvic contents densely matted, neither ovaries nor tubes distinguishable. Adhesions undisturbed; abdominal wound closed.	R.	Left the hospital Nov. 27, much improved in health.	—
18	M. B.	62	M.	Nov. 17, 1886	Exploratory incision for supposed ovarian cyst. Malignant disease of liver and peritoneum, with ascites and matting of intestines against post. abdominal wall. Fluid evacuated. Wound closed.	R.	Left the hospital in a fortnight. Wound healed; abdomen refilling.	—
19	E. G.	30	S.	Nov. 24, 1886	Cæsarean section in case of flattened and generally contracted pelvis. Conjugate diameter, $2\frac{1}{16}$ in.	D.	Child saved.	Communicated to Obstetrical Society of London

The operations in this table were all performed in the hospital.

Digitized by Google

this cause of failure could be largely eliminated. I am aware that some of our most successful operators reject the theory upon which the antiseptic method of Lister is based, and, without adopting the details of that method, have achieved brilliant results by scrupulous attention to cleanliness alone. But no one, I think, will deny that this minute and painstaking solicitude with regard to the cleanliness of hands, instruments, sponges, and dressings is the direct outcome of the teaching of Lister, and that even those who do not follow out his method in detail owe the improvement in their results very largely to the recognition of the great principle that underlies that teaching. Scarcely less important than the improvements already mentioned were the introduction of the glass drainage tube of Kœberlé and Keith, and the recognition of the value of dry and infrequent dressings, with the advocacy of which the name of the late Mr. Sampson Gamgee will always be honourably associated.

Again, there can be no doubt that the change for the better is partly to be attributed to the greater dexterity that comes of increased personal experience. Another cause that has influenced our results for good is the more general agreement that exists as to the desirability of operating early and the evils of preliminary tapping, the consequence of this being that practitioners send us their cases before they become quite so desperate, and before the constitution of the patient has become seriously undermined. Further, the interest of late years awakened in abdominal surgery has led to improvement in our methods of diagnosis, and cases of ovarian disease are now recognised at an earlier period of their development than was usual a few years ago.

Lastly, there are one or two circumstances special to St. Mary's Hospital, Manchester, that have materially contributed to lessen the death-rate after operation. During the earlier years of my connexion with the hospital, the board of management, noting the fact that Manchester and Salford provided the greater part of the funds for carrying on the work of the hospital, considered that the recipients of its benefits ought, as far as possible, to consist of persons resident in these towns; hence, they placed great restrictions on the admission of patients from out-lying districts. As a natural result of this policy, country patients drifted to other hospitals where admission was more easily obtained, while our patients at St. Mary's were drawn chiefly from the slums of Manchester and Salford, and largely consisted of women whom poverty and vice, and other unhealthy conditions, had rendered highly unfavourable subjects for operation. Six or seven years ago a wise change was introduced, and it is now as easy for patients from the country to obtain admission as those from the town. One other circumstance that has told in our favour must also be mentioned—viz., the anxious care manifested by the hospital authorities during the last few years with regard to the sanitary arrangements, which are now probably as satisfactory as they can be in so old-fashioned a hospital.

(To be concluded.)

A CASE OF TYPHLITIS;

EVACUATION OF LOCALISED PERITONEAL ABSCESS; RECOVERY.

BY ALBERT WILSON, M.D,
AND
RICKMAN J. GODLEE, M.S.

IN view of the difference of opinion amongst surgeons as to the best method of dealing with a localised collection of pus in the neighbourhood of the cæcum, when general peritonitis is supposed to have supervened on acute typhlitis, the following case may be of general interest.

H. S——, a groom, seventeen years of age, who had previously enjoyed good health, was said to have strained his side six weeks before he was first seen by Dr. Wilson, on Oct. 23rd, 1886. He complained of no symptoms till about the 17th, when he thought he took cold; this, at all events, was the date of the commencement of his illness. On the 21st and 22nd some rigors occurred, and on the 23rd he was brought to his home. He was then suffering from intense pain in the abdomen, especially on the right side, the tenderness here being so great that a complete manual examination could not be made. The temperature was 102·5°, and the pulse 100. The bowels at the commencement of the attack had been confined, but had been moved after some aperient medicine which had been previously given. Dr. Wilson at once ordered hot fomentations to the abdomen, and ten minims of tincture of opium to be taken every two hours, with some carbonate of soda to relieve the flatulence. On the 24th, 25th, and the early part of the 26th, the condition remained about the same, or rather improved, except that a swelling, small at first, was noticed in the right iliac fossa, which gradually increased to the size of a small orange. The tenderness, however, had diminished. On these days the temperature varied from 100° to 101°, and the pulse was always about 100, a little over or under. The tongue was thickly furred, and there was no action of the bowels. The treatment was continued, and the patient was fed upon beef essence, beef-tea, and milk in moderate quantities. In the evening of the 26th there was a sudden alteration in the symptoms, the pain and tenderness suddenly becoming much more acute and extending over the whole abdomen; so great were they, in fact, that he could not bear the weight of the bedclothes, and complained if anyone walked across the room. The temperature rose to 103·5°, and the pulse to 120, the latter being thready and weak. The countenance was ashy pale, and there were all the symptoms of collapse. It seems clear that at this time the peritonitis became general. Thirty grains of salicin were administered.

In the morning of Oct. 27th the patient's condition became worse, the temperature rising to 103°, but afterwards falling to 99°, and the pulse being 104, and hardly perceptible. Vomiting also set in, so that any food or brandy was at once returned. The breathing became altogether thoracic, and retention of urine occurred. He rallied, however, in the afternoon, and when we saw him together at 4 P.M. it was decided at once to make an incision into the now very marked swelling on the right iliac fossa. Chloroform was therefore administered, and a cut about three inches long was made by Mr. Godlee through the abdominal muscles below the anterior superior iliac spine, as if for ligature of the external iliac artery. In the deeper parts the tissues were infiltrated with inflammatory products, and when the peritoneum was reached and incised exit was given to about an ounce of extremely offensive pus. This occupied a small cavity, the posterior boundary of which was formed by coils of small intestine loosely held together by soft adhesions; but as the suppuration appeared to be completely localised, and as no pus welled up from the pelvis, the utmost care was taken not to break down these adhesions. The cavity was very gently swabbed out with a little solution of corrosive sublimate (1 to 500), and some iodoform was introduced; a drainage tube was inserted, and the wound was dressed with salicylic wool. It was decided to feed him with peptonised nutrient suppositories, and to keep him thoroughly under the influence of opium. After the operation the patient was somewhat relieved, though still very weak. Vomiting continued during the night, the material brought up having on one occasion a somewhat fæcal smell; indeed, the vomiting, though gradually subsiding, lasted for three days, only ceasing on the 31st. On the 29th the case was further complicated by the onset of diarrhœa, which prevented the rectal alimentation and lasted for a day or two. The vomiting and straining at stool caused a protrusion of a knuckle of intestine between the lips of the wound; the gut soon assumed a bright-red velvety appearance, and from its prominence prevented the reintroduction of the drainage tube. It became necessary gently to press the bowel back into the deeper part of the wound, and to retain it there by means of a pad of boracic lint kept in place by strips of plaster. The discharge in the meantime continued to be very fetid, and was expelled from the wound mixed with bubbles of air. For these three days the patient's state remained very critical, and we have to thank Dr. MacDonald, Dr. Wilson's assistant, for his unremitting care and attention during this period of the case. The temperature gradually rose from 97·8° to 99·2°, but the pulse fell from 130 to about 80.

Between Nov. 1st and Nov. 7th there was a gradual improvement in the abdominal symptoms and in the appearance of the wound, though the discharge continued to be offensive. The diarrhœa and vomiting had ceased, and the patient was able to digest peptonised corn-flour. He had, however, always an evening rise of temperature, which on one occasion reached 102·2°; the pulse also was again close upon 100. This increase of fever was no doubt accounted for by the fact that a small left parotid bubo occurred, which did not suppurate, but subsided without causing further trouble.

Digitized by Google

After Nov. 7th convalescence was uninterrupted, except on one occasion, when, after the bowels had been confined for a week, the temperature rose to 102°; they were relieved by an enema, and the temperature at once fell to normal. By Dec. 7th cicatrisation was complete, and the patient was sent to the seaside for a fortnight. He has since returned to his occupation, and remains quite well.

Most, if not all, will agree that as soon as there is distinct evidence of the presence of localised suppuration in the neighbourhood of the cæcum, it is the best practice to go in search of it; in other words, that the patient will have a better prospect of recovery if exit be given to the pus, than if he be left to the chance of the abscess bursting into the bowel. But there is room for differences of opinion as to whether, if there be signs of general peritonitis, it is not better to make a mesial incision, with the object of purifying the general abdominal cavity in the event of this peritonitis being purulent. It must be borne in mind that it is quite possible for general peritonitis to supervene after the formation of a localised peritoneal abscess, and that although the pus in the latter may be exceedingly offensive, the lymph or serum in the former may be, if not aseptic, at least free from smell. A case is recorded in the Transactions of the Clinical Society,[1] in which the same condition of things as that which was present in our patient was met with; but the diagnosis was rendered obscure by the absence of any marked local swelling. Here a mesial incision was made, and the intestines were found intensely injected from very early peritonitis. The abscess was first opened through the mesial incision, and the fetid pus was thus allowed access to the general peritoneal cavity. In spite of this, however, the patient made a good recovery; but it should be added that those parts of the peritoneal cavity over which the fingers and the pus had passed were, as far as possible, treated with corrosive sublimate solution (1 in 500), and that the abscess was drained through a second incision in the groin. The lesson to be learnt, if it be fair to generalise from a consideration of two cases only, appears to be that if pus be suspected in the neighbourhood of the cæcum, it is best at first to make an incision in the groin, even although there be reason to think that general peritonitis has set in. If the abscess be then found to be distinctly localised, all will have been done that is necessary. If, however, it be clear that the general peritoneal cavity is full of fetid pus, the surgeon may proceed to make a mesial incision with the object of gaining free access to the rest of the abdomen and to the pelvis, though it must be confessed that any attempt at purification under such circumstances is an almost hopeless task. The occurrence of the parotid bubo adds another to the long list of cases where an association between this condition and peritoneal inflammation has been observed.

A CASE OF COMPOUND FRACTURE;

AMPUTATION; SECONDARY HÆMORRHAGE; REAMPUTATION; RECOVERY BY PRIMARY UNION.

BY A. PIERSON, M.R.C.S., L.R.C.P. LOND.,
SURGEON, INDIAN MEDICAL SERVICE.

H——, aged twenty-eight, a Mussulman railway labourer, well nourished and healthy-looking, was admitted into a camp hospital on the Bolan State Railway on October 16th, 1886, with a compound fracture of the left tibia just above the ankle joint. The patient had been standing on a stack of loose rails, when one of them had turned over on its side and caught his leg. There was considerable bruising of the soft parts, but as the wound was small the hospital assistant in charge of the camp decided on trying to save the leg. He therefore syringed out the wound with carbolic lotion, dressed it with carbolic oil, and put up the leg in splints.

I saw the man for the first time on Oct. 29th. The discharge from the wound looked dirty, and the dressing could not be kept antiseptic. The patient was removed on a bed by train to the chief railway hospital, a distance of nine miles. On Nov. 5th I advised him to submit to amputation, as the discharge was profuse and offensive in spite of all carefulness in dressings. He stoutly refused, but on Nov. 8th he was put under chloroform and the leg amputated at the knee joint. This was necessary, as the skin was swollen and infiltrated lower down. On cutting out the posterior flap, I noticed that the skin was thickened and the subcutaneous tissue decidedly watery. A higher operation, however, was thought to be unjustifiable, as it was impossible to say how far the septic poisoning extended. The operation was therefore completed, and the wound dressed with iodoform and wool. His evening temperature before operation had been 99·8° or 100° for about six days. On the evening of the day of operation the patient's temperature was again 100°, but on the next night it rose to 103·8°. The wound was then dressed and found to be sweet, but the discharge was unhealthy.

Nov. 10th.—Morning temperature 100·4°. Discharge smelling. Evening temperature 103°.

11th.—The posterior flap is beginning to slough; it is commencing from a circular ulcer which has appeared between the two condyles of the femur, and has apparently been caused by infected lymphatics, as no pressure from bandaging could have been exercised on this particular spot, situated as it is between two bony prominences. After this the whole of the posterior flap sloughed off, leaving the two condyles quite bare and the artery visible between them. The temperature then fell to normal, and rosy granulations sprang up on all sides, and the artery was rapidly covered.

The temperature remained normal, with only occasional rises, apparently due to malaria, until Jan. 17th, 1887, when it rose to 100° in the evening. The wound caused by the sloughing of the posterior flap had gone on admirably at first. Then the patient's strength had begun to flag about Dec. 15th and a bedsore had formed on his sacral prominence, and after this the skin-forming had come to a standstill on the ulcer. At the end of December and beginning of January the granulations had a congested, flabby appearance.

On Jan. 20th—that is to say, two months and twelve days after the amputation—secondary hæmorrhage set in. The blood spurted from the granulations in three streams, one central over the artery and two lateral. Luckily, the assistant surgeon was on the spot, and at once applied an elastic band to the femoral artery. I decided to amputate again, seeing that the healing process had apparently stopped in the ulcer. Amputation was performed through the lower third of the thigh. Troublesome hæmorrhage (i.e., oozing) occurred after the operation, and the flaps were not closed for at least half an hour. Two hours and a half afterwards hæmorrhage came on again. The assistant surgeon opened the flaps, and found a small bleeding point which he tied. Two hours after this the dressings were again observed to be soaked through. I therefore again took off the dressings, washed out the flaps with a solution of perchloride of iron (1 in 8), sewed up the flaps, and applied two antiseptic sponges on each side of the incision. The stump was then firmly bandaged to the splint, and elevated on a high pillow.

Jan. 22nd.—Sponges removed and stump found to be quite sweet. Iodoform and wool applied. Temperature normal.

26th.—Wound dressed again for the purpose of removing the drainage tube and sutures. After this the wound required no trouble, and healed perfectly with the exception of a small collection of pus (about fifteen minims) which occurred in the course of a suture scar. This sent the temperature up to 100° on the ninth and tenth days after operation.

Feb. 20th.—Wound has been healed for some time, and the stump can be handled without causing any pain.

The amputated portion of the thigh was examined after the operation, and it was found that the granulations were large and flabby, and full of blood. They could be squashed like jelly beneath the fingers, and were easily peeled off the subjacent tissues. The prominent parts of the condyles on their posterior surfaces were carious and breaking down. This could not be seen except by first clearing off the granulations. The artery was traced down the popliteal space to the site of the ligature, and it was found to be pervious right up to it. There was no trace of the ligature (a catgut one), but the constriction was well marked. A probe easily went through, and the artery was found to be continuous with and moulded into a mass of large spongy granulations gorged with blood. I should not forget to state that the shaft of the femur when sawn through at the second operation did not appear healthy. The medulla bulged out like a watch-glass, and was abnormally congested.

Bolan Pass.

A CASE OF

OBSCURE ABDOMINAL ABSCESS; PERFORATING ULCERS OF STOMACH AND DUODENUM.

WITH REMARKS.

BY ANDREW MILLER, M.D. EDIN.

THE case here recorded is one of a class which present so much difficulty in diagnosis, and are therefore so difficult to treat successfully, that I feel it is a matter of great importance that each instance should be laid before the profession. At present but few observers have published cases resembling the one narrated below, and little or no mention of them is to be found in the standard works of reference, such as Leube's article in Ziemssen, &c. Under these circumstances, it is only to isolated pathological records that the profession can turn for information concerning these rare and dangerous groupings of symptoms. The following case, which occurred in my practice, may be briefly given.

For ten years before Mr. A——'s last illness he had been subject to attacks of abdominal pain, diffused in character, and referred to no particular region, but generally to the lower part and left side of the median line of the abdomen. These attacks occurred in paroxysms, there being sometimes an interval of from one to three months, during which there was complete immunity from suffering. The pain, which was very severe, but indefinite in character, was ascribed by the patient himself to cold or prolonged abstinence from food, and seemed to be wholly independent of the ingestion of ordinary solids or liquids, which, indeed, he could take with perfect impunity. Mr. A—— was a very abstemious man alike in food and drink. The attack of abdominal pain sometimes lasted only a night, but at other times was prolonged for two or three days; the severity of each seizure, however, generally spent itself in from twelve to twenty-four hours. The beginning of his fatal illness was looked upon by all concerned, himself included, as identical in character with what he had suffered before, the abdominal pain at this time not even being nearly so severe as on many previous occasions. In one instance, when I did not see him, the pain was so intense as to give rise to the supposition that it might be due to the passage of a gall-stone; however, there was no direct evidence of such having taken place.

On the morning of Nov. 30th, 1886, I was called to see Mr. A——. I found him in bed, looking pale, drawn, and pinched, complaining of dull, diffused, aching pain below the umbilicus and to the left side of the median line. I elicited that, owing to the pain, he had passed a restless and sleepless night. As he had been travelling by rail the whole of the previous day, and consequently had only taken hurried meals at irregular and unusual hours, his suffering was at first attributed to dyspepsia; no objective symptoms had up to this time developed themselves. Temperature 97·4°; pulse 100; bowels confined. Physical examination revealed nothing more than slight tympanites, general tenderness of the abdomen, some meteorism, but no tenderness on palpation over the stomach itself. Hot fomentations were applied to the abdominal parietes, enemata of a pint of hot water administered to counteract the constipation, and three-minim doses of tincture of nux vomica given every three or four hours. In the evening the temperature rose to 100·2°. The fomentations had somewhat relieved the pain, and the bowels had been freely opened. On carefully examining the abdomen, dulness on percussion and a sense of resistance to pressure, as if from some mass or obstruction, were noticeable in the left lumbar region of the abdomen just below and to the left of the small cul-de-sac of the stomach. This "tumour" was always more or less distinctly to be felt from this time to the close of the illness, but the distinctness with which it could be made out varied inversely to the degree of flatulent distension of the intestines. The night which followed was a very restless one; the patient slept but little, although the pain was sensibly diminished. Twenty grains of bromide were therefore administered on the third night, with very good result. During the next four days the temperature fluctuated from 100° to 102°, the diurnal variations being slight except on the third day, when the morning temperature touched normal. With this exception, pyrexia existed till the occurrence of the hæmatemesis, which was followed by the fatal collapse. In spite of this exaltation of temperature, for which quinine in two-grain doses three times a day was exhibited, up to this time the patient's condition had not caused special anxiety, as the present attack in all other respects resembled its predecessors before mentioned. The pain had yielded to treatment; the patient was cheerful and appeared to be making daily improvement, took food with some relish, passed quieter nights, and had more sleep. He was kept on the simplest diet—milk, beef-tea, and sometimes a little chicken or fish panada. From the sixth to the twelfth day the patient became more restless; the temperature assumed a higher range, exhibiting a marked diurnal variation, touching 102·8° on the tenth day, and with a variation of four degrees on the eleventh day. Thirst became a troublesome symptom, and the tongue was dry and furred. On the twelfth day there were two loose actions of the bowels. Early on the night of Dec. 12th (thirteenth day of illness) the bowels acted twice; the stools were liquid and the colour of tar, suggesting melæna; and about a pint and a half of dark blood mixed and diluted with the fluid contents of the stomach, was vomited suddenly and without pain. This was accompanied by a fall of temperature, which on the morning of the fourteenth day reached 98°, and subsequently to this, on the nineteenth day, when the patient died, the evening temperature never exceeded 99·6°, while the morning temperature kept about normal, being sometimes a fraction of a degree above and sometimes a little below normal. From this moment, when the hæmatemesis took place, till the close of the illness there was very marked prostration, amounting to collapse, so that transfusion of blood was contemplated, and a surgeon kept himself in readiness, and every preparation was made for carrying out the operation. The physical signs, with the exception of slightly increased tympanites, remained much the same as before. During this anxious period the respiration was of the Cheyne-Stokes type, and the pulse was exceedingly weak, compressible, and too rapid to be counted. There was a little wandering of the mind at times, while the countenance wore an anxious look. The patient was kept on nutritive enemata of beef-tea and brandy, nothing being taken by the mouth for about two days, water to rinse the mouth and ice to suck alone being allowed to enter the stomach. During this period one-sixth of a grain of morphia was given twice a day hypodermically. The hæmatemesis not recurring, he was allowed a little champagne and some meat juice and beef essence. In spite of all we could do, there was no rallying on the part of the patient, who died on Dec. 18th, the nineteenth day of his illness. The symptoms already recorded persisted until death, with varying intensity. It may be remarked that the urine, tested frequently during the illness, at no time exhibited a departure from health.

Necropsy twenty-seven hours after death.—On opening the abdominal cavity, the small intestines were revealed uncovered by omentum. This, together with the stomach, were afterwards found to be displaced upwards and backwards, so as to be hidden beneath the ribs. The former—that is, the omentum—was further found to be implicated with the tumour. The liver occupied its usual position, and in every way appeared perfectly normal. Upon drawing the small intestines aside, the tumour, which had been felt during life, was found to consist of a mass occupying a position to the left of the median line, extending from the hypochondrium to the inguinal region, irregular and somewhat oblong in shape. Its walls were in places half an inch thick, and appeared to be made up of inflammatory tissue together with adhesions formed with the omentum, mesentery, pancreas, colon, and duodenum, and probably the pyloric end of the stomach, but owing to the matted and displaced condition of the tissues and the friableness of the walls of the tumour any great precision on these points was difficult of attainment. The adhesions were very dense, firm, and evidently of old standing. On cutting into the tumour, it was found to contain a considerable quantity of offensive pus. Its interior was lined by smooth walls, to which shreds of curdy material were attached. The cavity was easily capable of holding a man's clenched fist. On opening the stomach, the mucous membrane was seen to be of a dusky hue. About three inches from the pyloric opening a minute punched-

Digitized by Google

out orifice was seen on the posterior lower wall. There was no heaping up or tumefaction about the edges, simply a thinning of the mucous membrane, and no signs of inflammatory change upon the visceral aspect. On passing a probe through the perforation, the probe was found to enter the cavity of the abscess described above. Similar but smaller communications existed between the abscess cavity and the stomach; these were situated somewhat nearer the pylorus. Upon cutting down the intestines, an aperture was seen in the wall of the duodenum quite similar to the larger perforation described in the stomach, which in its turn also led into the abscess cavity. No other outlets from the pus cavity existed. Close examination revealed that these various communications were funnel-shaped, the larger end of the funnel being away from the stomach and duodenum respectively. The visceral opening was exceedingly small indeed, so small that pus in this stage of the malady seemed unable to obtain free exit. The mucous membrane of the intestines below the duodenum was healthy, and, in fact, all the other viscera were free from morbid change.

Remarks.—In reviewing the above case, certain points appear to deserve special attention. The clinical phenomena were so ambiguous as to prevent a correct diagnosis being arrived at, and even after the necropsy it was found difficult, if not impossible, to trace the order of pathological events which led to the fatal issue. Dr. Bristowe published in THE LANCET of Sept. 29th, 1883, cases which bear some resemblance to the above, and which may well be studied in relation with it; but in these there was either a distinct history of gastric ulcer perforating and leading to abscess, which in its turn perforated, giving rise to fatal collapse, or of ulceration occurring in the intestines, which anticipated extra visceral abscess. Now, in the case of Mr. A—— there was a history of ten years: slight dyspeptic trouble marked by paroxysmal attacks and abdominal pain, without any hæmatemesis, melæna, or distinct pain after food relieved by vomiting—indeed, vomiting was wholly absent in this patient's case. There is not evidence, I think, sufficient to indicate whether these attacks of pain were or were not manifestations of localised peritonitis, although it must be admitted that the facts furnished by the necropsy would point to such a hypothesis. If this supposition—for it can only be viewed as such—be entertained, it would appear that the last illness was, in fact, a kindling into activity of a pre-existing chronic abscess due to such localised peritonitis. How far the interference with the alimentary tract arising from Mr. A——'s travel was responsible for this renewed activity in the abscess it is impossible to say. At any rate, the increasing size of the tumour apparently encroached upon the stomach and duodenum, and ultimately by a process of ulceration produced openings into these hollow viscera. In support of this view it should be remembered that, although the patient had been frequently and carefully examined, no tumour of any size could be made out till the occurrence of his last illness, and it is equally certain that the adhesions and thickening about the collection of pus could not have been the result of an eighteen days' inflammation. The assumption that the abscess was a sequence of the ulceration of the stomach or duodenum appears to me wholly untenable, and for the following reasons. There never were any symptoms of gastric ulcer until the advent of the hæmatemesis and melæna, which occurred five days before death; and the appearance of the perforations clearly indicated that they were produced from without into the viscera, the visceral opening being distinctly smaller than those looking into the pus cavity, while the mucous membrane in the stomach and duodenum in the vicinity of the perforation was absolutely healthy. It would appear that the purulent collection became infected probably through the thinned walls of the stomach or intestine, and took on a rapid infective course, leading to the hectic which marked the last attack, taking the abscess from the realm of harmless chronicity to that of a highly dangerous infective process. It is noteworthy that no general peritonitis existed, and that the patient at no time was the subject of rigors. In conclusion, I desire strongly to emphasise that I in no way wish to lay stress upon the explanation I have ventured to offer above. It appears to me to fit in with the facts as revealed by the necropsy. To others it may appear insufficient. My only object in bringing the case forward has been to state the facts of what I believe is almost a unique case. To others I would leave the explanation. The treatment throughout the case was practically one of expectancy. Judging after the fact, I regret that an exploratory incision was not had recourse to, for there is little doubt that such purulent collections, if diagnosed in time, might be treated by operative measures, with at least a fair hope of success.

Grosvenor-street, W.

THE INTERPRETATION OF DISEASE.

BY H. CAMERON GILLIES, M.B.

The meaning of the initial depression.—That the condition of depressed vitality, referred to in my last paper, obtains before every case of acute disease I am, for myself, fully satisfied. Indeed, I do not expect anyone will deny that it is so—being so simple, so apparent a fact in every case. What, then, is the cause of it? what does it mean? Many and ingenious hypotheses have been advanced to explain this condition when observed, and to explain what is commonly regarded as the disease—the acute violent attack that disables the sufferer. Very few of these can stand examination; most of them are not worth the trouble. They are, as a rule, matters of fancy, and, even as such, not very good guesses. There are a few, however, that claim and shall have attention. But before doing so I may be excused for resuscitating a little more of the commonplace.

"The human body, like that of any other animal, is an organism in which by the chemical changes of its constituent parts potential is converted into kinetic energy, and these changes depend upon the presence within the body of energy-yielding substances."[1] It must be clearly understood that the body of itself has no inherent power whatsoever—that it lives and moves and has its being by virtue of energy and substance received from its environment. "Whatever amount of power an organism expends is the co-relate and equivalent of a power that was taken into it from without."[2] Not only are the larger and more apparent forms of action, such as of manual labour, under this law, but every organic act also; every beat of the heart, every movement of respiration, every twinkle of the eye, is under the same law, and implies so much energy spent, however small that may be. The principle goes even further than that. "No idea or feeling can arise save as the result of some physical force expended."[3] We now arrive at this, that no act whatsoever of mind or of body, however small and insignificant, whether voluntary or involuntary, in health or in disease, can have origin or execution except it be from physical energy derived from food taken into the body and there digested and assimilated. We cannot of ourselves by any effort of will generate the least conceivable quantity of vital energy. Every thought and every act implies the transformation in our bodies of so much organic matter as contained the energy spent on them in a latent state. In the human body there is no constant measure of energy. It varies not only at different periods of life, but from day to day and from hour to hour. There is, however, during the period of maintenance or adult life in a healthy person, an average measure of potential energy, the total sum of which day by day is perhaps approximately constant. This potential energy of maintenance is what has been appropriately called the physiological capital of the individual. It is really the true expression of the individual vigour, and determines the height of the *health line*, to which our most serious calculations are referred in the estimate and treatment of disease. The food we eat from day to day sustains the current account of our physiological transactions. It would be wrong, however, to adhere too closely to this analogy, for there is no distinction of kind or place between the physiological capital and the current account. The energy received at any given time is incorporated with and assimilated to the potential capital; and from the sum is drawn the measure that becomes kinetic in our life acts. The fact to remember is that the capital from day to day gives an approximately constant sum. That is the condition we call health.

A theory is advanced by Dr. W. B. Carpenter, which, because of the honest endeavour it shows in the direction of truth and of the measure of truth in it, and because it has had very general acceptance, is of some interest: "Ample

[1] Hermann's Physiology (Gamgee). [2] Herbert Spencer. [3] Ibid.

Digitized by Google

evidence is afforded by army experience of the special liability of soldiers to zymotic disease when on long and fatiguing marches, because, the respiratory process being reduced by the high external temperature, the products of waste tend to accumulate in the blood"—and so the organism is predisposed to disease. The *fact* here expressed is correct and valuable, but I venture to say that the explanation and the interpretation of it are wrong. The author himself seems to have had his suspicion, for he gives a further explanation in support: "There can be no doubt that it lowers the healthy vigour of the body generally, and thus renders it more liable to disease." That is good. All the facts of the case are there—all the elements that are necessary to get at the truth. We have labour, wear and tear of body-structure, and a great expenditure of energy; and as a consequence of these, exhaustion and fatigue and liability to disease. But surely the waste products, the débris of the spent tissues, are not here the *cause*. That a depression of the healthy vigour renders the body liable to disease is true—it is, in fact, the whole truth; but that the waste products are the cause of that depression is wrong. We cannot accept it that any result can predispose to produce its own cause—that the child is the progenitor of or determines its own grandfather. The labour is the cause, and that the waste products accumulate is only an accident and a part result of the real cause. Dr. Carpenter refers to the fetid secretions, excretions, and exhalations, and to the rapid putrescence of the victims to the Irish famine of 1847, in support of his theory; and he attributes all this to the uncleanly condition and habits of the people preventing exhalation from the skin of the waste products in the blood. But there is no meaning in saying that in such cases, as of famine, waste accumulates in the blood. The whole body is a waste product. There is not anywhere in the whole body a healthy part. It dies in the mass. Every tissue and cell is so far famished and diseased. Energy is not, and cohesion is not. The "internal relations" are exhausted; the "external relations," the forces of destruction and putrefaction, operate without any resistance, and because of that there follows all the conditions detailed. Properly considered, a victim of famine is dead before he dies. It is not correct to measure decay from the moment of total extinction, for it commenced when the body first began to suffer the effects of famine, and destruction is far advanced before the last flicker of life. The poor tenement of clay that is for our purpose the instrument of life fails not in any one part or organ, but in its total mass, and it is no wonder that "rapid putrescence" sets in after death. With every respect, I submit that the theory of Dr. Carpenter entirely fails—that it cannot be accepted as a guide or as an aid to the true interpretation of disease.

"It becomes a very interesting question," says Mr. Simon, "by what manner of action different kinds of privations are able to produce inflammatory excitement. Just in the same way as the setting sun produces darkness or the absence of its rays cold, it is not a positive product but a negative." There is an error here, of the *post hoc propter hoc* kind. It is not the privation that produces the inflammation, as shall be shown later on. The question is, however, of great value, and that especially because of his own answer: "In the present state of knowledge the only conceivable explanation is that the excitement is secondary, that a certain amount of textural death is the primary and direct result of the privation, and that the inflammation is a consequence." This doctrine, that textural death is the cause of inflammation, is of the very highest interest. I am disposed to accept it in its broadest and most comprehensive application—to give it, perhaps, more value than Mr. Simon meant it should have. That textural death is followed by inflammation in cases of traumatic injury is evident; we all see that. It is therefore extremely interesting to find Mr. Simon's theory coming into straight line at a long distance with facts so plain as to need no proof. Inflammation follows wounds we all know; it follows on privation, causing textural death, Mr. Simon tells us. In the one case the textural death is substantial and visible, local and sudden; in the other it is general, perhaps, and gradual, and, at any rate in its early stages, quite beyond the powers of our senses to detect. But the one is as real and as much a fact as the other, and they are both identical in purpose and effect. It matters not whether the disease be a simple cut, a broken leg, or a pleurisy—there is textural death, and textural repair follows in direct proportion to the textural vitality, to the physiological capital, to the potential energy of the individual, and destructive processes in the inverse ratio of the same. We die daily in the strictest physiological sense. Every second of our lives is a long history of physiological operations in which death and repair run parallel in our bodies. "We are kept from dissolution by foreign powers, and not by any powers in ourselves." If the natural and necessary textural death of physiological change overcome or exceed the parallel process of repair and restoration or restitution of tissue elements, then that is death actual in that measure. We may call the moral expression of it weakness or even disease; and if it proceed beyond recovery, it is dying, and, finally, total death, when the potential energy is run out. Malaise, weakness, disease, and death are in one and the same straight line. "*Predisposition to disease and disease are the same thing*" is the invaluable expression of John Brown, and therefore all the cause or forces of predisposition—defective food and warmth, overwork or dissipation, unhealthy surroundings, &c.—are also in the same straight line with disease and death. So that even Mr. Simon falls short of stating the whole truth. His "structural death" on which inflammation (disease) follows is itself secondary to a loss of energy that has gone before. The *dis*-ease is the expression of the functional derangement that is the necessary result of the textural death following on the primary loss or defective supply of energy to the organism. Disease in the accepted sense is therefore the fourth remove from the prime cause. All this listlessness and indisposition, flying pains and neuralgia, blood poverty and irritability or sleeplessness, loss of appetite and general weakness—the whole condition thus and otherwise variously described—are so many points in the inclined plane that extends from our remotest adverse environment downwards through all the gradations of disease till it end in death.

Several very interesting lines of thought invite attention at this point, but considerations of space forbid.

Brockley, S E.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

SUCCESSFUL REMOVAL OF AN ABDOMINAL CYST OF EXTRAORDINARY SIZE.

BY A. W. MAYO ROBSON, F.R.C.S. ENG.,
HONORARY SURGEON TO THE LEEDS GENERAL INFIRMARY, AND LECTURER ON PRACTICAL SURGERY AT THE YORKSHIRE COLLEGE.

OVARIOTOMY being such an ordinary operation, it would be quite unjustifiable to report a single case were it not that it presents special points of interest.

In saying that a patient, aged thirty-seven, was admitted to the Leeds General Infirmary on May 10th, 1887, suffering from abdominal tumour, it would be almost more correct to describe it as the admission of a huge tumour with a patient attached, had it not been for the fact that the woman actually walked from the cab to the ward. There was a history of fourteen years' abdominal enlargement, and of rupture of the cyst six years before admission due to a severe shake, the fluid being passed off through the kidneys at the rate of four pints a day for about three weeks. Her general health had been fairly good until the pressure, which had produced great œdema of the lower extremities, had interfered with her nutrition and had impeded locomotion. The appearance of the patient was most remarkable: thin and careworn, she lay on her side, coiled round her immense abdomen, which was nearly six feet in circumference two inches above the umbilicus, the tumour occupying the bed and the patient being pushed to the edge. She could only with difficulty lie on her back or left side on account of dyspnœa, and had to lie on her right side or to be propped upright. The ribs were expanded like alæ, the lungs were pushed upwards, and the apex of the heart was felt in the third left intercostal space, one inch and a half above the nipple and half an inch from the anterior axillary line. Very large veins coursed over the abdomen, which presented the usual signs of an ovarian tumour. From the length of time it had existed, the slight effect, except

Digitized by Google

from pressure, on her general health, the history of rupture without peritonitis six years before, and the presence of a very distinct wave as of thin fluid in one cyst, I diagnosed the cyst as parovarian, and from the fact of rupture I anticipated adhesions. At the operation on May 24th this turned out to be the case; the cyst was growing from the left broad ligament, to which it was attached by a pedicle, thus enabling it to be removed without interfering with the contiguous ovary. It was very extensively adherent over the front and upper part of the abdomen, and had some adhesions to the viscera both in the abdomen and pelvis. The cyst contained no less than eighty-five pints (ten gallons and a half) of fluid, of a dirty grey colour; specific gravity 1026, alkaline, and containing much albumen. A Keith's drainage-tube was used, which was removed on the fourth day, there being no discharge from it after the second day. Recovery was slow but uninterrupted, save for an attack of dyspnœa on the third and fourth days, apparently due to the heart and lungs being displaced and trying to regain their position. Relief was given by ammonia inhalation, and by firmly padding the abdomen, which was collapsed and perfectly flat.

It may be that cysts as large have been removed; but I cannot find the record of such a one, and I can safely say that I personally never previously saw one nearly as large.

Leeds.

BILHARZIA HÆMATOBIA.

By E. B. HARTLEY, V.C.,
SURGEON-MAJOR, CAPE MOUNTED RIFLEMEN.

IN THE LANCET of April 30th, 1887, I notice certain notes on this subject taken by Mr. W. K. Hatch in Bombay. It may not be out of place for me to offer a few remarks on the same disease as it occurs in King Williamstown, Cape Colony. For some years I have encountered occasional cases of hæmaturia among soldiers of the Colonial Forces. The numbers are limited. It is not until recently that I have treated numerous cases among boys and youths of ages varying from ten to eighteen years; the disease being clearly owing to the presence of the parasite bilharzia hæmatobia. The disease appears to be very common in this town among European lads. I have heard of no cases among females. The history is generally similar to that of the following case:—

A. B——, aged fifteen, a pale, anæmic, ill-grown youth, for three years or so has remarked blood in his urine. It generally comes at the termination of micturition, sometimes as pure blood, at other times it is intimately mixed with the urine, or lumps of congealed blood settle at the bottom of the vessel, the urine under the last circumstances being clear. There is sometimes pain, but in the majority of instances it is absent. The blood is worse after playing football or cricket or after taking any violent exercise. Has received no injury to the bladder, and can assign no reason for the advent of the blood in his urine. Does not feel ill, and knows a great many boys who have had the same complaint gradually get over it and appear to be none the worse afterwards. Has been in the habit of bathing a great deal in the river, but has been advised to discontinue doing so, as the doctors say this is the cause of the disease. Is in the habit of drinking rain water which is collected from a corrugated iron roof and stored in a barrel. The urine upon inspection appears either dusky coloured or intimately mixed with blood, and in some cases there are clots of mucus and epithelium at the bottom of the vessel. Under the microscope ova, as pictured by Cobbold and other observers, and described under bilharzia hæmatobia, are readily seen, the numbers varying in proportion to the quantity of blood. In only one case have I been able to detect the parasite itself. No opportunity of making a post-mortem examination has been afforded me. The disease is by no means common in the higher altitudes of this colony. During a residence of three years in Basutoland, some 5000 feet above the sea, I met with only one case, and that was an Indian coolie from Natal. As a general summary I would affirm that the disease is rare amongst grown-up men, but very common among boys; that it lasts from three months to three or four years, and that it does not appear to do any permanent damage to the individual. In two cases I have noted blood as being passed with the motions.

Treatment——tions of medicated lotions into the bladder I regard as perfectly useless, besides being very objectionable to the patient. I have tried quassia, iodine, carbolic acid, iron, nitrate of silver, hamamelis, iodide of potassium, gallic acid, &c. By the mouth I have given endless and varying drugs—ergot, gallic acid, hamamelis, acetate of lead, belladonna, buchu, matico, hyoscyamus, turpentine, carbolic acid, almond mixture, cod-liver oil, mercury, syrup of iodide of iron, santonin, &c. I cannot affirm that any of these have done much good. It is, however, pleasing to record that Blaud's pills (ferri sulph., gr. iiss., potas. carb., gr. iiss.), as described by Ringer in his book of therapeutics, afford very material relief to the symptoms, and in several cases a cure. I commence with three pills a day, and as soon as it is seen that the digestive organs are not upset, I increase the dose to six pills in the day. They must be persevered with for some two or three months. Other preparations of iron appear to be useful, but I cannot speak of them with the same confidence as being likely to reduce the quantity of blood passed. At present I am treating fifteen cases with it.

King William's Town, S. Africa.

SYMPATHETIC AFFECTIONS OF THE EARS.

By F. W. BENNETT, M.D.,
HONORARY ASSISTANT PHYSICIAN TO THE LEICESTER INFIRMARY.

Two cases which have occurred recently in my practice seem to present examples of a sympathetic relation between the ears.

The first was a man, aged about twenty-five, who had suffered from deafness for several months. The hearing distance on either side was about six inches. On examination mucus was diagnosed as being present in the middle ear on both sides. I incised the membrane on the left side, and by syringing through a Eustachian catheter removed a considerable quantity of mucus. The hearing distance increased to more than two feet. To my surprise there was a corresponding improvement on the other side; this latter was, however, only temporary, and had disappeared three days later. The left ear continued much better, but no further improvement occurred on the right side until I removed mucus by incision.

The second case is more interesting. A painter, somewhat anæmic, complained of recent deafness and pain on the left side, with constant humming on the right. On examination I found a recent collection of cerumen on the left side but nothing abnormal on the right. I syringed away a soft ceruminous plug from the left ear, when the patient said that not only had the deafness and pain gone, but the humming on the right side had ceased.

Possibly in the first case excitement, due to the unpleasant operation, so stimulated the auditory nerve as to render its perceptive power temporarily greater. In the second case, however, there was no excitement, no prolonged syringing required, and nothing whatever was done to the right ear. I could not but conclude that the soft plug had sufficed in the patient's anæmic condition to set up irritation, causing pain on the same side and tinnitus on the opposite.

Leicester.

MYELOID SARCOMA OF UPPER JAW; REMOVAL OF SUPERIOR MAXILLA; RECOVERY.

By ALFRED E. HIND, F.R.C.S.

THIS case was treated by me while I had charge of the Jersey General Hospital. It is in no way remarkable except for the very rapid recovery and almost complete absence of deformity.

Mrs. K——, a woman aged forty-two, came to the out-patient room on May 26th, 1886, complaining of a painful growth between the canine and second bicuspid teeth on the upper alveolus on the left side. She stated that about two years previously a decayed tooth (first bicuspid) had been extracted, but that after extraction the wound never healed, and she soon noticed a fleshy nodule projecting in its site. This nodule has been growing slowly since.

On admission into hospital there was found between the canine and second bicuspid teeth a projection from the alveolar margin. It was softer than the normal gum tissue and covered with mucous membrane; its colour was dark

Digitized by Google

red. The nasal fossa on the affected side was not encroached upon. There was a little depression of the palate on that side, but so slight was it that it was scarcely noticeable. The cheek was, on careful comparison, found to be perhaps a little raised. The orbit was not affected. On the day after admission I removed the second bicuspid tooth. With it came away a piece of what was evidently sarcoma tissue. There was a little bleeding. The alveolar walls were found to be separated by a soft new growth which extended upwards into a distended antrum. On May 31st, the patient being under chloroform, I removed the superior maxillary bone, after reflecting a cheek flap. This was done by an incision extending through the upper lip in the middle line passing round the ala of the nose up to within about half an inch of the inner canthus, and thence passing outwards to the malar prominence. There was free bleeding for a moment while the cheek flap was being dissected up, but this was arrested by firm pressure. After separating the attachments of the bone by means of bone forceps, the bone was found to be so much thinned that it was impossible to get firm hold of it with a pair of lion forceps. It was easily removed piecemeal with a pair of parrot-bill forceps. It was found necessary to remove almost the whole of the floor of the orbit, as the new growth was attached to its under surface. The cavity was firmly plugged with dry lint and iodoform, and the edges of the wound brought into apposition by sutures. No dressing was applied except a piece of lint soaked in ice-cold water. The whole external wound healed by first intention. Patient's temperature never rose above 100°. She left the hospital on June 19th with a strip of lint lightly plugged into the cavity. By the middle of August she was able to wear a set of artificial teeth, the plate of which completely covered the deficiency of the palate. The scar was almost imperceptible, and no deformity resulted. On July 12th of the present year there was no sign of any recurrence. As the tumour was a myeloid sarcoma, encapsuled and confined to the superior maxilla, the whole bone having been removed, the chance of its recurrence is not great.

Jersey.

TYPHO-MALARIAL FEVER.

By J. G. LAFFAN,
COLONIAL MEDICAL SERVICE.

THERE prevails in the Mediterranean a fever known variously as "Rock," "Levant," "Mediterranean," or "Cyprus" fever, according to the name of the locality in which it occurs. A disease running a similar course is known on the west coast of Africa as "coast" fever, in Western Australia as "colonial," and soldiers are familiar with "Peshawur" fever on the north-west frontier of India. All cases of this fever resemble one another; but, as a rule, they can be divided into classes.

Class 1—and I have found that the greater number of cases may be placed in this class—contains all those cases in which great fluctuations of temperature, with or without rigors and sweating, are observed, in addition to many of the typical signs of typhoid fever. This class of cases I propose to call "malario-typhoid," as signs of malaria predominate.

In Class 2 I would place all those cases, so common in tropical climates, in which are found nearly all the signs of typhoid (the rash is generally absent), but in which abnormalities occur pointing more or less to the presence of malaria. To such cases the term "typho-malarial" seems peculiarly appropriate.

The differential diagnosis of these two varieties is difficult during the first week of the attack. At the end of that time, in most cases of Class 1, the tongue, which had been, hard and dry, brown-furred and red-edged, becomes moist and clean; if diarrhœa has been present (and it generally is) it ceases, or changes from its typhoid character, the patient's mind becomes clear, and he convalesces; but generally slowly, the temperature remaining high, sometimes for weeks, and most likely one or more relapses will take place. On the other hand, cases of Class 2 run on a course more or less nearly resembling ordinary typhoid fever. Surgeon James, of H.M.S. *Téméraire* (to whom I take the liberty of referring), has, I believe, in his possession notes and temperature charts of several cases of Class 1.

The treatment I have adopted in this fever or these fevers has been, for the first week or so, expectant and sustaining afterwards being guided by the symptoms, adopting a course based upon the diagnosis of the nature of the poison present. I am happy to be able to add that up to the present I have been successful.

Wyndham, Cambridge Gulf, Western Australia.

THE FORCEPS IN MIDWIFERY CASES, WITH COILS OF FUNIS AROUND NECK OF FŒTUS; ALSO IN PUERPERAL CONVULSIONS.

BY T. OSBORNE-WALKER, M.R.C.S.

QUITE recently I have had under my care four cases of lingering labour, presenting a singular coincidence of symptoms and attendant circumstances, as infrequent, irregular, and inefficient pains, with retrocession of fœtal head on subsidence of pain—the presentation being occipito-anterior vertical in all the cases. Three out of the four I delivered with Sir James Simpson's long forceps and one with Dr. Greenhalgh's short forceps, though I experienced difficulty with the short forceps in consequence of the high position of the head, not having any long forceps with me at the time. Of the four cases the last happened to be the most difficult, as the head of the fœtus receded almost beyond touch of the examining finger after cessation of pain, without introduction of the hand into the vagina; and this occurred to a multiparous woman, who had borne twins in her immediately preceding confinement. Two of the cases were primiparous and two were multiparous, and in all the funes were convoluted tightly around the necks of the children; and both mothers and infants—though two of the latter were greatly asphyxiated at birth, requiring vigorous application of resuscitative means to revive them—have since progressed most satisfactorily. In two cases of puerperal convulsions I have also applied the forceps with marked success, the convulsions ceasing and consciousness returning immediately on delivery of the fœtal head, mothers and infants alike surviving and doing well. In my early practice days I had a case under my care with the cord tightly applied in two convolutions around the child's neck, necessitating its division to safely complete the birth; and in a subsequent case there were not only two tight coils encircling the neck of the fœtus, but both clenched fists were compressing the cord externally, partially overlapping the horizontal ramus of the lower jaw, and a foot interposed, also external to the funis. This state of things I rectified, and the infant, born limp, pale, and apparently lifeless, I was enabled to resuscitate.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

WESTMINSTER HOSPITAL.

CASE ILLUSTRATING THE VALUE OF THE INDUCTION BALANCE FOR DETECTING A NEEDLE IN THE THUMB.

(Under the care of Mr. RICHARD DAVY.)

THE use of the induction balance and telephone, as applied in the case recorded, was undoubtedly of the greatest value in proving the presence and localising the position of the foreign body. The publication of this case will again bring before the profession the value of its use in those obscure injuries in which foreign bodies of a metallic character are lodged, when other definite indication of their presence is absent. For proof of the lodgment of bullets, slugs, &c., at the time of their infliction, the military surgeon has to trust to the evidence obtained by examination of the part, &c., and cannot utilise such a delicate instrument as that described by Mr. Hawksley. In cases, however, where the missile has been lodged for some time and search with the ordinary instruments has failed, it will doubtless be more employed

Digitized by Google

in the future, and that with success. The notes of the case were taken by Mr. Gordon Green, dresser.

T. D——, aged thirty-seven, late corporal 40th Foot, was admitted into the Mark ward on March 17th, 1887. Ten weeks previously the man was scrubbing a floor, and felt something sharp enter the ball of his right thumb. He went to a hospital, and a surgeon probed the small wound, ordered the man poultices, and kept him under observation for six weeks. He had obscure pain about the ball of the thumb, for which blisters had been applied. Not feeling satisfied, and believing that a needle was yet in his thumb, he came to Westminster Hospital.

When seen, the man's right thumb was painful, and at a small spot in the palm was an eczematous rash, at which point the needle had entered. Surgical examination proved nothing, for no needle or foreign body could be felt on careful manipulation, nor could the patient feel any foreign body, though he had sat long by night and by day trying to settle all doubt as to whether or not any needle was there. Under these circumstances Mr. Davy and Mr. Lownds paid three visits to Mr. Hawksley, on March 18th, 19th, and 22nd, with the patient. Mr. Hawksley not only showed every attention, but favoured Mr. Davy with a report, which is as follows:—

"The apparatus used was essentially the same in principle as that invented by Professor Hughes, and named an 'induction balance.' Its first application for the purpose of detecting a bullet in the human body was that made by Professor Bell in the case of the late President Garfield. There are three uses of this beautiful electrical arrangement: (1) for the detection of the presence of metal in the human body, (2) as an audiometer, and (3) as a means of detecting most minute differences in the mass or alloy of gold or silver coinage. It consists of the following parts: from two to six Leclanché or bichromate elements; a simple microphone, arranged to indicate the ticking of a clock or other source of constant, regular sound; then two double bobbins or pairs of reels of wire, one reel in each pair being of thick wire and forming a primary coil, which is in circuit with the battery and microphone, the other reel in each pair being of fine wire, in the circuit of which is a telephone; the current passing through these latter reels and the telephone is a secondary or induced current, induced by the proximity of the two primary reels. One of the pairs of reels is attached to a box, and is not used for searching. The two reels comprising this double bobbin are held together by elastic bands, but may be separated at will by means of the fine adjustment of three ivory screws. To this latter bobbin is attached the other double reel, or 'searcher,' by means of long conducting cords. This reel is of a convenient size and shape to move about with facility, is made hollow so that prominent parts may be enclosed by it, and, moreover, it may be made of various sizes. Some art as well as technical skill and experience are required to so adjust the fixed coils that the sound of the microphone is not heard in the telephone; but by careful adjustment, absolute silence may be produced, and the two sets of coils or bobbins are then said to be balanced. When this is done the search for a needle or bullet may be commenced by means of the movable coil.

"This instrument need not be used if the presence of the metallic foreign body is evident by the sense of touch or probe explorations; but where these have failed to detect its presence or localise it sufficiently to warrant the surgeon operating, then it is well to use the balance. The evidence it gives is unmistakable, if it be a witness at all, for it simply says metal is or is not in the region examined. It is sufficient, therefore, to know about the neighbourhood where the metallic mass is suspected to lie, and the balance will localise it, often with great precision. The 'searcher,' which the movable reel may be called, is taken in one hand and applied to the surface of the body, the telephone is carefully placed to the ear, and the balance tested for silence. This being found correct, the searcher is slowly moved in parallel lines over the part supposed to contain the metallic body. On detecting the slightest sound in the telephone the searcher is removed and tested for silence. This being found still correct, the searcher is again applied to the body, and, if the silence is again broken, mark the spot through the aperture in the reel. Then begin the search at right angles to the former lines of examination until the silence is again broken, and at the point of maximum disturbance mark the position. A very little manipulation will now enable the searcher to be placed over the spot on the body where the greatest resonance is obtained, and beneath that the metallic object will be found. To define the depth of the metal beneath the surface or its size need not be entered upon here.

"In the case of the needle in question, no indication whatever of its presence was obtained by searching outside the thumb, but on inserting the thumb inside the hollow reel of the searcher, at one particular angle, the pattering sound of the microphone was faintly but unmistakably heard, and the correctness of the indication of the instrument was demonstrated by the result of the operation.

"In a previous case under the care of the late Francis Mason, the patient, an American, had shot himself by placing the muzzle of his revolver into the external orifice of the auditory meatus. Where the bullet was could not be determined; it was searched for by means of the electrical probe of Trouvé, and also the chemical probes of Hawksley On applying for the first time practically the balance test, and after a little searching, a loud sound was heard in front of the patient's ear, though the area of this sound was rather large for a bullet. Nothing else was suspected until the brother of the patient, who was present, inquired if 'gold filling' would interfere with the indications. An examination of the patient's teeth in the upper jaw showed them to be extensively filled with gold, hence the loud sound and its extensive area. From the elementary description of the apparatus which has been given it will be evident that its indications will be very reliable in the hands of an expert; the presence of any other metal in the neighbourhood of the searcher, whether that of a coat-button, a watch-chain, or the ironwork of an ordinary bedstead, must be borne in mind in the endeavour to discover such an inferior electrical body as a common leaden bullet. 'If,' as Professor Bell remarks, 'people would make their bullets of silver, copper, or iron, there would be no difficulty in finding them in any part of the body.'"

The man's suspicion and the surgical opinion being fortified by Mr. Hawksley's examination, Mr. Davy proposed operation to the patient, but not before he had subjected Mr. Hawksley to a crucial test. He showed Mr. Hawksley one needle and a dead hand, informing him that he would place the needle in the hand while he was absent from the room, and then he, by the aid of the searcher, should tell him where it was. During Mr. Hawksley's absence Mr. Davy cut the needle into two and rammed them deeply by means of a pair of tweezers into two fingers. On re-entering, Mr. Hawksley at once spotted correctly the long and ring fingers, and accused Mr. Davy of having used two needles instead of one.

On March 24th, the man being placed under the influence of chloroform, Mr. Davy made a small puncture in the belly of the man's thumb with a tenotomy knife, about midway over the metacarpal bone; using the tenotome as a probe, the needle was, after some searching, felt distinctly. The puncture was enlarged, and the sides of the wound gently retracted; the end of the needle was lifted upwards by tilting, and extracted by an ordinary pair of small pliers. It was the broken point of an ordinary stocking needle, and measured three-quarters of an inch long.

Remarks by Mr. DAVY.—This bit of needle seems to have been lodged between the flexor brevis pollicis and adductor, in some position parallel to the metacarpal bone, and under cover of the bone. This shelter seems to have prevented the patient from experiencing pricking pain. The plan for getting at the needle reminds me of the bet made by oak-rippers that their axe shall hit the same mark on a tree twenty times running. They make their first cut, and then nineteen strokes follow at right angles to the first. So in this case the needle was discovered by using a tenotome (as a probe) at right angles to the suspected track of the needle. In all these doubtful needle cases any diagnostic help is of value; wavering was steadied, suspicion was confirmed, and all were pleased at the valuable assistance rendered in this instance by the induction balance.

NEWCASTLE-ON-TYNE INFIRMARY.

THREE CASES OF COMPOUND FRACTURE OF THE SKULL; TREPHINING; RECOVERY.

(Under the care of Dr. HUME.)

THE following cases, for the notes of which we are indebted to Herbert Bramwell, M.B., C.M., house surgeon, may be of interest to some at a time like the present, when so much attention is being devoted to the surgery of the cranium and its contents.

Digitized by Google

CASE 1.—W. D——, aged twenty, was admitted on Feb. 24th, 1886, having received a blow over the left eyebrow with a sharp piece of iron, rendering him unconscious for half an hour. Two hours and a half after admission he was conscious, but suffering from shock, with dilated pupils, the left being more so than the right. There was an irregular wound, about an inch in extent, extending from the inner part of the left orbital ridge over the nasal eminence. The orbital margin and adjacent bone were fractured and slightly depressed. On opening the wound free hæmorrhage took place from the divided supra-orbital artery. Considering the small extent to which the bone was depressed, and its relation to the sinuses, it was thought possible that the internal table of the skull might not be injured. Any operation was therefore postponed, and the wound dressed. During the next few hours, after recovering from the shock, the patient vomited several times.

No symptoms developed until Feb. 26th, seven days after the accident, when the following notes were made:—Morning temperature 99·5°; pulse 45, full, with a slow laboured beat. The patient has been very drowsy and lethargic all day, complaining of pain in the head, and is very irritable if disturbed. The pupils are irregular, the left being larger than the right. The wound is suppurating slightly, but is clean and healthy-looking. Evening temperature 100·5°; pulse 40.

March 1st.—The patient has been in much the same condition. The frontal headache still continues.

2nd.—Morning temperature 102°; pulse 48. The lethargy and irritability on being disturbed are more marked. Dr. Hume considered the symptoms indicated inflammatory compression of the brain, and determined to remove the depressed fragment. On exposing the bone, a considerable portion, measuring half an inch in its longest diameter, was found depressed. By removing two small triangular portions of bone from the lower angles, the depressed portion was elevated, when it was found that the inner table had been extensively comminuted. One irregular fragment, the size of a sixpence, was projecting edgeways on to the dura mater. The orbital roof was splintered, several spicules pressing inwards on the membranes. After carefully removing all fragments, the two triangular portions of bone removed by the saw were replaced in position, and the periosteum, which had been carefully preserved, was stitched over them with catgut sutures.

The after-progress of the case was very satisfactory. The general aspect of the patient improved as soon as the effects of the chloroform had passed off; all signs of lethargy and irritable temper soon disappeared. The replanting of the portion of bone was not successful, and delayed the healing of the wound. A small part of one portion formed adhesions, but the other pieces came away as sequestra some weeks afterwards.

CASE 2.—J. S——, aged twelve, was admitted into the infirmary on April 28th, with the following history: About an hour before admission he was hit on the head by the shaft of a cart going at a quick pace, and knocked down insensible. The loss of consciousness lasted only a few minutes.

On arriving at the hospital he walked into the accident room, and seemed little the worse for the injury. On removing the handkerchief which had been applied to the head, a large irregular cut was found on the left side, its centre being situated two inches and a half above the zygoma, and one inch behind the external angular process of the frontal bone. The bone was found extensively comminuted and depressed, and brain substance protruded from between the fragments. The pulse was regular, and beating 72 to the minute. There was no muscular rigidity or paralysis, and he was able to give an accurate account of the accident. After the head had been shaved and thoroughly cleansed, chloroform was administered, and Dr. Hume removed two irregular fragments of bone each about the size of a halfpenny which were depressed on the dura mater and almost completely stripped of periosteum. Several smaller splinters were also removed. During the operation about a drachm of brain substance escaped through a tear in the dura mater, an inch in length, and extending transversely across the wound. This tear in the dura mater corresponded to the position and direction of the transverse frontal fissure. The dura mater was not stitched; a small drainage tube was placed in the lower angle of the wound, and the skin margins drawn together with silkworm gut sutures. The operation was performed under the carbolic spray, and antiseptic treatment pursued throughout the case.

The after-progress of the case was remarkable by the entire absence of symptoms of any kind. The boy recovered rapidly from the effect of the operation, and was quite cheerful next day. There were no signs at any time that the brain had been injured. The wound healed without suppuration, the temperature never reaching 100°. After cicatrisation a space the size of a florin remained, unprotected by bone, through which the cerebral pulsations were communicated to the skin. A flat silver plate has been provided to protect this portion of the brain, and which the patient wears continually without any inconvenience.

CASE 3.—P. M——, aged fifty, a strong, healthy man, was admitted on Jan. 20th, 1887, suffering from a compound comminuted depressed fracture of the frontal bone. The fracture was caused by a blow with the corner of a block of wood, which had been projected with great violence from a circular saw. He was knocked down, but not concussed, and walked the distance of one mile to the infirmary. When admitted he was faint, but had no other symptoms. There was an irregular wound over the right frontal eminence, leading to a large circular depressed fragment of bone, round the margin of which three smaller fragments could be made out.

Two hours after admission, chloroform having been administered, Dr. Hume enlarged the wound by a T-shaped incision, exposing the fractured portion. It was then seen that a portion of the entire thickness of the frontal bone, measuring an inch and a quarter by one inch had been driven inwards and downwards, its lower margin projecting for a quarter of an inch between the dura mater and the bone. Three smaller portions of bone were bent inwards around the lower end of the wound. The whole formed a firmly impacted depressed mass, quite immovable. A small trephine was placed over the upper angle of the wound, and a semicircle of bone removed, exposing the superior angle of the large fragment. By laying hold of this with a pair of sequestrum forceps it was withdrawn in an upward direction. After the removal of this portion the three smaller fragments were elevated with ease, and, being completely detached from the periosteum, were removed. From under the margins of the surrounding bone five small splinters of the inner table were extracted. These were irregular sharp fragments, which would undoubtedly have given rise to meningeal irritation if they had not been discovered and removed. The dura mater was abraded at the upper part of the wound, but not completely torn through. The portions of bone removed, when placed in accurate apposition, measured two inches in their longitudinal, and one inch and a quarter in their transverse, diameter. In stitching up the wound the sutures were made to include the whole thickness of the scalp and whatever portions of periosteum remained. A small drainage tube was inserted at the lower angle of the wound. The carbolic spray was used during the operation, and the wound cleansed with corrosive sublimate lotion.

Recovery took place without a hitch, there being no fever and very little suppuration. The drainage tube was removed on the third day after operation, the stitches on the sixth. The patient was allowed to get up on the tenth day after the operation, the wound being firmly healed; he went home on the thirteenth day after admission. Two months after the operation the cicatrix had contracted to half its former size, and a firm thick covering occupied the site of the fracture.

Remarks by Mr. BRAMWELL.—These cases may be taken as strong recommendations to the immediate removal of depressed bone in compound fractures of the skull. When the operation is performed at once, with complete antiseptic precautions, it will rid the patient of the dangers of septic meningitis, and the surgeon's mind from visions of sharp fragments sticking into the membranes. In any depressed fracture of the cranium one cannot be certain that there are no spicules of the inner table irritating the dura mater; and until this doubt is removed, the surgeon must always be in an anxious state about his patient. Considering, then, the small danger of trephining the skull with antiseptic precautions, the old saying, "When in doubt, operate," would certainly seem the most comfortable to follow.

IT has been decided to establish a Throat and Ear Hospital at Nottingham, and a committee has been appointed to take the necessary steps.

ACADEMY OF MEDICINE IN IRELAND.

Injury to Cranium at Birth.—Extra-uterine Fœtation.—Urine Reactions.—Abscess of the Uterus opening through the Umbilicus.

AT a meeting of the Obstetrical Section held on May 6th,

The PRESIDENT (Dr. MACAN) said he had taken the unusual course of bringing a living child, in care of its mother, for exhibition, the child being a remarkable example of the extent to which an infant's cranium might be injured at its birth without its health being seriously affected. It was a second child. The child was delivered by turning. The woman's pelvis was narrow; and it caused a great depression on the child's head, which had become less since its birth, but was still very marked. The child was slightly asphyxiated after birth, but had been since in perfectly good health, and had given the mother no anxiety. In other cases of narrow pelvis in the hospital the children had been delivered without injury to their crania, but had afterwards died, some of them in an inexplicable manner, within a week.

The PRESIDENT also exhibited a rare case of Extra-uterine Fœtation. The woman had a suspension of the menses for three months, and then was suddenly attacked one day with violent pain in the abdomen, and fell down in a state of collapse. She was put to bed, and remained there for five weeks before she was brought to the Rotunda Hospital. When she arrived there she was in great pain. He found a tumour extending up to the umbilicus. She gave a positive history of pregnancy, and on squeezing her breast a considerable quantity of fluid came out. After she had been for some time in the hospital he thought the posterior cul-de-sac more indicative of fluid than it had been, and determined to aspirate. He did so, and the first syringeful of blood that came away was quite black, but the next was so bright that he withdrew the needle at once. Symptoms of increasing collapse ensued, and after nine days she died. Dr. M'Kee made the post-mortem examination. On cutting through the uterus, a large blood clot was found in the posterior cul-de-sac. The fœtus was found in the abdomen. There was also a fibrous tumour. The sac in which the fœtus must have been was recognisable, but the condition of the clot and tumour was such that the place in which the fœtus had developed could not be determined.

Dr. R. H. FLEMING showed the Decidua removed from the cervix of a patient shortly before death, who was suffering from profuse internal hæmorrhage, the result of a ruptured extra-uterine pregnancy, probably tubal.

Dr. ALFRED SMITH exhibited specimens of Urine Reactions. The urine had been taken from a woman who had suffered from puerperal convulsions. Four days before the attack she had great pain in the abdomen with frontal headache, and the convulsions were started with epigastric pain and great depression about the chest, and small and rapid pulse. The reactions were divided into four groups, representing urine drawn off at different times—viz., the first at 6 P.M. on April 30th, shortly after the woman was admitted into the Rotunda Hospital; the second at 2 P.M. on May 1st; the third at 10.30 P.M. on the same day; and the fourth at 6.30 P.M. on May 6th. Specimen *A* of the first group showed a half bulk of albumen; *B* a heavy peptone reaction; and *C* well-marked acetone. Specimen *A* of the second group showed albumen one-half by bulk; *B* heavy peptone reaction; and *B* acetone. Specimen *A* of the third group showed one-eighth of albumen by bulk; in specimen *B* peptone was absent; and in specimen *C* acetone was absent. In the fourth group Specimen *A* showed a tenth of albumen by bulk; in specimen *B* peptone was absent; and in Specimen *C* acetone was absent. The testing of the urine took place after the convulsions. The quantity of it was perfectly normal before she came in.

Dr. J. R. FITZPATRICK related the case of an Abscess of the Uterus, opening through the Umbilicus, in which an abdominal tumour appeared three weeks after delivery, in shape and size corresponding to the uterus at the seventh month of pregnancy. The tumour reached from the pubes to an inch above the umbilicus, became adherent to the abdominal walls, and after four weeks an abscess discharged through the umbilicus. The matter discharged was thick and putty-like, in large quantities, and very fetid for some days. There was not much pain, but very rapid pulse, and varying temperature, running up at night to 103° and 104°. A drainage tube was passed in at the umbilicus, and for several days the abscess cavity was irrigated with a solution of boracic acid, in hot water (1 in 40). The feverish symptoms subsided after some days, the discharge ceased, the tumour diminished in size, and the patient made a good and perfect recovery. A similar case is described by the late Professor Schroeder, in vol. x., p. 99, of "Ziemssen's Cyclopædia of the Practice of Medicine." — Professor BENNETT said that as it devolved on him to have a large part in the active treatment of this case, he desired to make a few observations. The pelvis was flat at the sides, back, and vagina, and was quite free. The only feature that pointed to the uterine character of the affection was the upward elongation of the uterus. The opening was near the summit of the tumour and was extremely small; and, in the absence of precedent, the question was whether, as the symptoms were urgent, it would be wiser to dilate the opening with a knife, or to adopt the slower method of gradual dilatation, as he was apprehensive that there might be adhesions along the point of exit. A remarkable symptom was that whenever the tumour was compressed, the woman felt a desire to urinate. The path of the opening was along the urachus, and, as he felt some delicacy in using the knife there, he adopted the slower course of dilatation. Spots of pyæmia appeared, and he was inclined to lay the tumour open, but did not do so for fear of infecting the abdominal cavity. The abscess originated subsequently to labour, and had a duration of between three and four months. A remarkable feature in connexion with it, which he never saw in any other abscess, was that the contents were reduced to such a condition of solidity that a great force of irrigation had to be employed in order to dislodge them. The whole tumour was full of material which was firmer a great deal than butter. Such rapid degeneration of pus he had never seen in so short a period as between three and four months. The material consisted of nothing but a mixture of detritus of pus and oil. The question of its size was a difficult one to decide. It was not in the uterine cavity, because there never was any discharge whatever of pus from it; and he believed that it must have been situated in the sub-peritoneal tissue of the upper part of the body of the uterus. It was the only example of the kind he had ever seen. At one period of the case he thought that there was a suppurating ovarian cyst which had become adherent; and he also thought that it might be a case of extra-uterine fœtation, and that they would come on the débris of the fœtus. Whether he was right or wrong in the course he took of slow dilatation, the result of the case had been successful. The rapid restoration to health of the woman, the moment the contents of the abscess were entirely cleared away, showed that the case was neither one of an ovarian tumour which had suppurated nor one of extra-uterine fœtation in which the fœtus had decomposed. The only difficulty was the removal of the putty-like material which the abscess contained. As he had said, he feared to make a free opening in the abdomen, not knowing the limitations of the canal through which the pointing took place, and, as irrigation was adopted, it was necessary to employ a free stream, and the only question was what antiseptic should be used. They could not use three or four pints of mercuric, iodoform, or carbolic solution; the only antiseptic that could be employed in the necessary quantity was boracic acid, and that solution proved most efficient.

Lumbo- and Laparo-colotomy.

At a meeting of the Surgical Section, held on May 20th,

Mr. THOMSON read a record of two cases of Colotomy. In the first, which the patient survived twenty-one months, a tube about the size of small intestine was found in the position of the colon, and between that viscus and the kidney. He was assisted by the late Professor M'Dowel and Professor Thornley Stoker, neither of whom could recognise it. The latter thought it might be an enlarged ureter, but on puncturing it with an angular needle two or three times nothing escaped. The tube was left *in situ* and the colon was opened. The patient made a good recovery. In a drawing of a frozen transverse section he showed how, if the colon had a long mesentery and was distended by flatus, it could extend forwards past the jejunum, lying on

Digitized by Google

its outer side, and, overlapping that portion of the intestine, appear second in order from the quadratus lumborum, and not first. In the second case, fæces did not appear for seventeen days. The patient was aged seventy-one, and, although the wound was entirely healed, he died on the twenty-third day after operation. Both operations were done for cancer of the rectum.

Dr. BALL read a paper on Colotomy, illustrated by five cases, in three of which the lumbar operation was selected, while in two laparo-colotomy was performed. He advocated the adoption of the latter operation in the adult as well as the child.—Mr. TOBIN, while confident of a consensus of opinion in favour of early operation, was equally sure that the cry could be carried too far, and that there were "too soon" operations as well as "too late." When there was malignant stricture of the rectum, inflammation might be remedied by palliative treatment, and when it subsided the bowel would carry on its work. He had had a case in point—one of stricture of the rectum—that almost occluded the bowels. Having tried palliative treatment and given enemata, he found the bowel could carry on its work fairly well. He taught the patient to use Higginson's syringe. Subsequently the patient was admitted into the Hospital for Incurables, yet in a condition to go to a garden party when he had the opportunity. Therefore that a surgeon could not operate too early was not to be taken as a rule.—Dr. CHANCE observed that his colleague, Dr. Coppinger, in order to identify the intestine, passes through the stricture a very small catheter, and then a stilette through it.

Reviews and Notices of Books.

A Practical Treatise on Diseases of the Eye. By Dr. EDOUARD MEYER, Prof. à l'Ecole Pratique de Médecine de Paris, &c. Translated by FREELAND FERGUS, M.B., Ophthalmic Surgeon to the Glasgow Royal Infirmary. London: Charles Griffin and Co. 1887.

CONSIDERABLE courage is now demanded of anyone who will undertake to write single-handed a complete treatise on the diseases of the eye. In Germany, the vast collection of independent treatises which have been collected by v. Graefe and Saemisch in the "Handbuch" supply evidence of the wide extent of the ophthalmological knowledge of the present day, and of the depth to which it has been carried by many earnest workers. In France, both De Wecker and Galezowski, though masters of the craft, have found it expedient to avail themselves, in the compilation of their larger treatises, of the services of younger men; whilst Sichel appears to have been unable to get beyond his first volume. The work before us, which has been excellently translated by Dr. Freeland Fergus of Glasgow, is not quite a new work, but it is greatly enlarged as compared with former editions, and has been almost rewritten. It has certainly been well brought up to the knowledge of the present day, and may be regarded as in all respects a very trustworthy guide for the practitioner, who, whilst possessing a fair knowledge of eye diseases, is yet unable to avail himself of the services of an ophthalmic surgeon. The volume has been very well got up by Messrs. Griffin, and the type, woodcuts, and chromolithographs are alike excellent.

The mode in which Professor Meyer deals with each subject is thoroughly practical; a short anatomical introduction precedes the description of each part of the organ, as of the cornea, iris, and retina, but no attempt is made to treat these subjects exhaustively. They are only described so far as may be requisite to render the nature of the pathological processes intelligible.

We venture to notice a few subjects which have attracted our attention in looking through the work. In speaking of the treatment of purulent conjunctivitis, Professor Meyer recommends cold compresses in the early stages, with scarification of the mucous membrane and division of the external canthus, and thinks that astringents and caustics should be avoided. We do not think that scarification is often practised in England, nor is the external canthus frequently, though it may be occasionally, divided. With us the sac of the conjunctiva is generally sedulously washed out with boracic acid or some other antiseptic; and lead lotion, which is here recommended, is rarely employed, lest a white deposit should occur on the cornea. Professor Meyer is opposed to the abortive method in the earliest stages, but when the purulent nature of this disease is clear, caustics in the form of a strong solution of lapis divinus, acetate of lead, or silver nitrate may be employed, the latter being used preferably in the form of mitigated nitrate. This method has not in our hands proved very satisfactory, and we are inclined to rely a little more on general treatment, such as quinine and iron.

Of Sympathetic Ophthalmia, with the symptoms of which every practitioner should be familiar on account of the serious issues in which it may terminate, Dr. Meyer recognises four forms: sympathetic irido-choroiditis, which very frequently ends in complete blindness; sympathetic serous iritis, which is much less dangerous; sympathetic chorio-retinitis, which has hitherto only been observed by v. Graefe; and sympathetic neurosis, which is characterised by the absence of any material change in the structure of the eye. Dr. Meyer points out that the means of transmission of the irritation may be along the ciliary nerves, along the optic nerve, and along the vessels; whilst the presence of micrococci in the intra-vaginal space after the injection of microbes proves that sympathetic ophthalmia may be of an infectious nature. In regard to treatment, he recommends the removal of the injured eyeball as the only certain means of preventing the development of sympathetic ophthalmia; other proceedings being section of the anterior ciliary nerves behind the point of tenderness, or section of all the ciliary nerves behind the globe, either with or without section of the optic nerve. We think the author might have expanded this chapter with great advantage. Imagine a case occurring to a country practitioner in which a child has received a cut with a knife in the ciliary region. What shall he do? If he refers to the work before us, he obtains little information. The excision of the eye seems to be the only course open to him, if he wishes to place the child in absolute security; but the child may see very well, and parents or friends may object to such extreme measures, and we think with justice. The nature of the wound is of some consequence in determining the question. A stab with a fork, as in attempting to open the knot of a bootlace, is much more dangerous than a cut with a piece of glass. The temperament of the child is an element in the prognosis. Enucleation should be practised on an irritable child, whilst it might safely be postponed in one of placid disposition. Nothing is said of the propriety of pad and bandage applied to *both* eyes, and perfect rest in the dark for a week or ten days, by which means dangerous consequences may often be averted, and so on. The question of the removal of an eye is a very serious one, and the surgeon is not unfrequently placed in a dilemma. If he leaves it alone and sympathetic ophthalmia supervene, he is blamed for the result and for his non-interference; if he removes the eye immediately, he is blamed for acting precipitately, and for being only too anxious to operate.

We have noticed a few slips which, in view of a second edition to which the work will assuredly run, may prove of service to the translator. Page 57, line 15, "chymotic" should be "chemotic"; page 189, "Streatfield" should be "Streatfeild"; page 22, "The disease has till now been rarely observed," should be "The disease up to the present time"; page 237, "Fentana" should be "Fontana"; page 320, line 15, after "sooner" the words "or later" require to be inserted; page 391, line 18, instead of "a lens made of a convex sphere," read "a convex lens made from a sphere"; page 401, line 8 from bottom, for "preserves" read "preservers"; page 402, line 16, "Prismatic glasses are also used in *ophthalmology*," should be "in ophthalmic surgery" or "in ocular therapeutics"; looking to the derivation of the term, they can hardly be said to be used in "ophthalmology." Some proceedings are described rather fully that have fallen into entire disuse and are not likely to be again practised.

Digitized by Google

A very high tribute of praise must be given to Dr. Freeland Fergus for the general character of the translation, which is extremely readable and at the same time very accurate. The work may, as a whole, be regarded as a faithful epitome of the present state of ophthalmological science, and may be fully relied upon as an index of treatment for ordinary affections of the eye.

The Climatic Treatment of Consumption. By JAMES ALEX. LINDSAY, M.A., M.D. London: Macmillan and Co. 1887.

THIS book is one which is not only eminently readable and suggestive, but clear and concise, and is evidently the outcome of an extended personal experience. The writer, who has visited most of the health resorts of the world, is enabled to bring to bear upon his subject information which, coming first hand, is of the highest value, whilst he has evidently studied the question of medical climatology with great care. The chapter devoted to the mountain sanatoria has in great part appeared in our columns, when it attracted attention from the manifest grasp that the writer had of the facts for and against these now highly fashionable resorts. Dr. Lindsay displays the same judgment and discretion in dealing with ocean travel, whilst the chapter on Australia abounds in facts that will be gladly welcomed in this country. He distinguishes between the characters of the littoral region, the highland region, and the region of the inland plains, the last named alone being the most suitable for invalids—to those, at any rate who can adapt themselves to the mode of life; but he proves clearly that in the large towns on the littoral, especially if the patient continue the sedentary vocations of his home life, the benefit he will derive may be *nil*. Very significant are the details of mortality from consumption in Melbourne and rural Victoria in this respect. In the city it amounts to 2·5 per 1000; in the country to only 0·87 per 1000; so that the rate at Melbourne is as high as in rural England, and not much below that of London (3·2 per 1000). The climatological characters of Tasmania (where the Australian invalids resort in summer to escape the hot winds of that season) are next described. This island is "one of the most picturesque little spots in the world," contrasting strikingly with "its great and prosperous, but uncomely neighbour." The northern and eastern coasts seem to be the most equable. The death-rate of the island is about 15 per 1000, whilst the mortality from consumption is but little over one-third of the British rate, and the quietude of the place renders it peculiarly suitable for invalids; but as its climate is more damp than Australia, and changes of temperature are frequent, it is not considered suitable for the permanent residence of the consumptive. In New Zealand, where there is great prevalence of wind, and a very considerable rainfall, the death-rate from consumption is rising steadily, and it is not to be preferred as a residence for the consumptive to the Riverina of New South Wales, or the Darling Downs of Queensland. Dr. Lindsay wisely points out the undesirability of this remarkable country for the invalid, however attractive for the tourist. A short chapter on Southern California serves to indicate the dryness and warmth, with absence of wind, which point to its utilisation as a health resort, although it is not much developed. The Cape, objectionable on the coasts from the prevalence of winds, is barred to the delicate invalid from the discomfort of travel and accommodation in the interior, where the climate is most suitable. Algeria is described as the favourite among the new health resorts for the consumptive, but the author speaks with hesitation, from the existence of such drawbacks as an imperfect water supply and the presence of much dust. He considers, however, that the idea that Hamman R'Ihra is unsuitable for a winter residence is overrated. But little, in fact too little, space is allotted to the description of the health resorts of Southern France and of the home country, and it would be well if in a future edition the author were to expand these subjects. It would add greatly to the utility of the book. Some mention should also be made of Madeira and Oratava, and of Egypt. Of especial value is the chapter upon the choice of a climate for the consumptive; for we may fairly say that no question is more difficult for the physician to decide, or one which entails so much responsibility. As an aid towards enabling him to arrive at a right decision this book is sure to prove of service, and we have little doubt that it will be widely read and appreciated. The subject is one, too, which engages the attention of patients as well as doctors; and it is highly important that it should be discussed without prejudice and in a scientific spirit. Dr. Lindsay has certainly succeeded in fulfilling these requirements, and we may be contented to have drawn attention to a work which will do much towards placing on a sounder basis the appreciation of the relative merits of health resorts.

Scheme of Case Reporting. Arranged by W. H. ALLCHIN, M.B., F.R.C.P. London: H. K. Lewis. 1887.

Notes on the Physical Diagnosis of Lung Diseases. By J. MAGEE FINNY, M.D. London: H. K. Lewis. Dublin: Fannin and Co. 1887.

DR. ALLCHIN'S scheme has at least one distinctive merit. It is by far more detailed than any similar work with which we are acquainted. To some this may seem to be a questionable advantage, as tending to confuse the student in his bedside examination; but Dr. Allchin has anticipated such criticism, and we are inclined to agree with him that nothing ought to stand in the way of obtaining a complete clinical record of a case. A few cases worked out thoroughly upon the lines laid down in the Scheme would be a most useful educational exercise. It is, however, as a complete guide or reference that the Scheme will probably be most utilised by house-physicians and clinical clerks; and it is produced at a price which will bring it within the reach of all. We have carefully gone through its pages, and can safely say that there is not a point in the clinical history and examination of a medical case that has been omitted.

Dr. Magee Finny's little book, based upon the instruction given in his class, simply aims at recording the methods of physical examination of the chest and the nomenclature of physical signs, with their significance. The author's reputation is sufficient proof of its accuracy, and its size is conveniently portable.

Dermatitis Venenata: an Account of the Action of External Irritants upon the Skin. By JAMES C. WHITE, M.D., Professor of Dermatology, Harvard University; Physician to the Out-patient Department for Skin Diseases, Massachusetts General Hospital. Boston: Cupples and Hard. 1887.

THE title "Dermatitis Venenata" is applied to those forms of inflammation of the skin which are produced by the direct action of irritating agencies externally applied, and in this treatise Professor White has collected much reliable information on the subject, which has not been hitherto accessible to the practitioner in a convenient form. The bulk of the work is taken up by a consideration of the action of plants on the skin; then follows an account of other irritants, organic and inorganic; and lastly, the author treats briefly of animal irritants. The nature of these irritating agents, and the conditions under which they come in contact with the skin, are most varied. They excite inflammatory processes of all degrees of intensity, characterised by certain primary efflorescences, such as the hyperæmic macule, a wheal, a papule, vesicle, bulla, or pustule, and by such secondary lesions as scaling, excoriation, scabbing, ulceration, scars, and pigmentation, and these lesions are indistinguishable from such inflammatory lesions as eczema, erythema, and urticaria excited by internal agencies.

The botanical tastes of Professor White have made this work an agreeable labour, and it is throughout written in a scholarly manner. The treatise will be useful, and we cordially recommend it to the profession.

THE LANCET.

LONDON: SATURDAY, JULY 30, 1887.

THE consideration of the Estimates in the House of Commons on the 22nd inst. gave opportunity for objections to be raised to that part of the vote which related to vaccination administration in England and Wales. Usually the opposition is limited to the few anti-vaccinationists who become members of Parliament, but their number was on the present occasion strengthened by the Irish members, who, following Mr. ARTHUR O'CONNOR, objected to this item, on the ground that it was a special and exceptional allowance limited to England and Wales alone. Mr. O'CONNOR was supported by Dr. GAVIN BROWN CLARK, who gave as the ground of his opposition that Scotch medical men did not receive any portion of this grant for vaccination. Mr. RITCHIE, however, explained that the Act of 1867, under which awards to public vaccinators are made, was limited in its application to England, and that if its provisions had extended to Scotland, that part of the kingdom would receive a share of less than £100. In regard to Ireland, he observed that the vaccinating officer was also the dispensary officer, who was partly paid from Imperial funds, and that altogether Ireland was at no disadvantage. The combination of members who for these various reasons opposed the vote numbered only sixty-six.

The arguments raised against the operation of vaccination were of the same sort as those to which the House has each year to listen when the subject comes under discussion, the same stock statements were made as to the injuries which follow from the enforcement of the Vaccination Acts. As an illustration of the reasons given for Parliamentary inquiry into the working of the Acts may be mentioned the statement of Dr. CLARK that he had himself "vaccinated from children suffering from syphilis; he could not help it, because he did not know the antecedents of the child from whom the lymph was taken."

Mr. RITCHIE, in an able reply, expressed his doubt as to whether the opposition to compulsory vaccination was really increasing; but if it were, he said, he should not feel in the least astonished, because the gross misrepresentations by anti-vaccinationists as to the effect of vaccination, which were constantly placed before the people, and especially the working classes, in our large towns, could fully account for any growth of opposition to the law. He pointed out the great saving of life that had been effected by vaccination, and claimed for the Local Government Board that every case of alleged injury was investigated and the facts concerning it fully stated. The Board, indeed, deserve much credit for the full accounts of the working of the Vaccination Acts that are given each year in the reports of their medical officer, and which show that only some 5 per cent. of children in this country escape the operation of the Acts. It is true that in some few localities the proportion of children who are left unprotected against small-pox is much greater than this; but these places are essentially those in which the inhabitants are deceived by the misrepresentations referred to by Mr. RITCHIE, and it may safely be asserted that for the rest of the kingdom no widespread opposition to vaccination exists.

The proposal of Dr. CAMERON, that the use of calf lymph should be more largely extended, is a point upon which we have frequently expressed our views. The work of the Animal Vaccine Establishment has certainly shown that excellent results attend the direct vaccination of children at that institution. If calf lymph, however, were to replace humanised lymph throughout the whole country, it would necessitate the use of stored lymph, and the more certain arm-to-arm vaccination would have to give way to vaccination having a less assured success. No sufficient reason has ever been shown for thus changing a system which has practically banished small-pox from many parts of the country, and has greatly reduced its prevalence in others; nor do we believe that the opposition to vaccination which is now carried on by a few misled enthusiasts would be overcome by any such alteration of method as that which Dr. CAMERON proposes. The silence which the anti-vaccinationists have hitherto observed with regard to the use of animal lymph would at once be broken if the current vaccination of the country required its universal employment.

The supporters of vaccination have no grounds for fearing the result of any inquiry as to the value of the operation which might be instituted, but it has to be remembered that the mere fact of such an inquiry being held would itself be regarded by the ignorant as casting doubt upon the efficacy of this means of preventing small-pox, and would afford direct encouragement to the opponents of vaccination to persevere in efforts which have already in certain places been attended by an unfortunate success. It is possible for the Vaccination Acts to fall into abeyance in Leicester and some other towns without immediate calamity following from this negligence, but as the populations gradually revert to a state of susceptibility to small-pox, it is certain that in the future a terrible mortality will result, and the mouths of anti-vaccinationists will be for a time silenced. It is lamentable that such experience is needed for those communities which persistently refuse to learn the lessons taught by the past.

AT the present time, when corrosive sublimate has established its claim to the title of being the most powerful and the most efficacious of all known antiseptics, and has therefore passed into general use, but has, on the other hand, caused many untoward accidents, the experimental work of DOLÉRIS and BUTTE[1] is opportune and valuable. These observers, desiring to elucidate the causes of mercurialism, especially in obstetric medicine, compared the effects of vaginal and other injections in animals (dogs, rabbits, and guinea-pigs) when the mucous membrane was (*a*) intact, (*b*) wounded. The strength of the sublimate solution was 1 in 1000.

(*a*) Experiments when the mucous membrane was intact gave the following results. In dogs, the first vaginal injection of one litre of the solution was generally followed

[1] Nouvelles Arch. d'Obstétrique et de Gynécologie, No. 12, Dec. 25th, 1886, p. 739.

Digitized by Google

the next night by simple yellowish or by blood-stained diarrhœa, and often by the vomiting of food. This affection was, however, transient, and lasted only a few hours, the animals rapidly recovering on the second day. The temperature was not affected. However long the injections were continued, to the amount of two or three litres daily, no further effect was produced. This acquired immunity seemed to be due to alteration in the vaginal mucous membrane, which was noticed to become dry, hard, and thickened, and presumably non-absorbent.

(*b*) As regards sublimate injections after injuries to the mucous membrane, the results varied with the nature of the wounds. If these were slight, the effects might amount to slight diarrhœa, but generally there were no results at all. To produce fatal results it was necessary to produce extensive and saccular wounds, allowing the fluid to stagnate, or to continue the injection for a long time. These experiments were made on rabbits, guinea-pigs, and dogs.

The rodents seemed very easily poisoned by the sublimate; in some cases death occurred within twenty-four hours, and no marked pathological lesions could be observed. In most cases death occurred at between two and three and a half days (forty-eight to eighty-four hours), and with marked changes in the large intestine and kidneys. The temperature gradually sank and became subnormal (33° C.), and the animals became rapidly weaker and unable to stand. The urine appeared to be diminished; it became slightly albuminous after the second day; it reduced the cupro-potassic test, forming a dark yellow liquid, but not the precipitate characteristic of sugar. This reaction may have given rise to the assertion of diabetes as a result of mercurialism, and a similar reaction is recorded by one of the authors in a patient under mercurial treatment.

The post-mortem appearances are practically as follows. The cæcum and colon show submucous hæmorrhages with sloughs of the mucous membrane in places. The kidneys are somewhat enlarged, and in a condition of acute parenchymatous nephritis; their surface is pale, and shows some white dots. On section the cortex is pale and almost entirely composed of yellowish-white streaks, which are straight tubules full of calcareous deposits, which, when treated with sulphuric acid, show crystals of sulphate of calcium. The medulla is congested, the pyramids are reddened, and contrast markedly with the pale cortex.

Dogs seem less sensitive than rodents to sublimate intoxication. Sometimes they do not die at all, sometimes after four or five days. The temperature does not sink till towards the fatal termination. Diarrhœa, with tenesmus and blood-stained stools and vomiting, always begins the night after the sublimate injection, and continues throughout. The first few days dogs do not seem very ill, but towards the end they lose flesh and strength, remain recumbent, and fall on trying to rise. In one case death was preceded by convulsions, with subnormal temperature. Perhaps the convulsions were uræmic. The urine is always albuminous, and gives a yellow colour with the cupro-potassic test. There is no change in the hæmoglobin of the blood, its power of absorbing oxygen not being diminished. Death follows in from four to twelve days, and, as in rodents, the earlier the more sublimate is used. The causes of death appear to be principally the renal changes; the quantity of urea in the blood increases considerably in the last days of life. As a rule there is no salivation. In cases rapidly fatal the liver and pancreas are sometimes congested; this congestion is not observed when death ensues slowly. The other appearances are the same as in rodents, with the following differences: no ulceration of the bowels is found, and no calcareous deposits in the renal tubules, which are filled with renal epithelium in a state of fatty degeneration.

The practical conclusions point to the caution necessary to be observed in the use of sublimate after delivery, on account of the surgical injuries present. The temperature is oftener raised in women than in animals, probably on account of the greater intensity of intestinal lesions, and the peculiarity of the placental site in women favouring sepsis. Rise of temperature is, therefore, at best, only an indirect sign of mercurialism, while depression of temperature, especially if gradual, points directly to it. The daily examination of the urine will show early albuminuria and the yellow colouration above mentioned; that of the blood will show the accumulation of urea. The presence of mercurialism does not prevent septicæmia. These experiments, which of course require confirmation from clinical observations on women, are meanwhile of great importance.

THE inadequacy of medical incomes is not a pleasant subject, but it is not one which can properly be ignored; on every ground it is one that should be explored and demonstrated. The duties of the medical profession are not such as can be adequately discharged by men whose living is precarious or whose remuneration is mean. This is not an original remark, but was made more than a hundred years ago by so sound a writer as Dr. ADAM SMITH. One or two of his sentences are worth reproducing:—

"We trust our health to the physician; our fortune, and sometimes our life and reputation, to the lawyer and attorney. Such confidence could not safely be reposed in people of a very mean or low condition. Their reward must be such, therefore, as may give them that rank in society which so important a trust requires. The long time and the great expense which must be laid out in their education, when combined with this circumstance, necessarily enhance still further the price of their labour."

It may be said that SMITH had in view exclusively the case of highly cultivated physicians who moved and practised among the rich; but this is not so. He applied the same principle *mutatis mutandis* to the general practitioner, or, to use the language of his day, the apothecary.

"The skill of an apothecary is a much nicer and more delicate matter than that of any artificer whatever, and the trust which is reposed in him is of much greater importance. He is the physician of the poor in all cases, and of the rich when the distress or danger is not very great. His reward, therefore, ought to be suitable to his skill and his trust."

We cannot give space for the whole interesting paragraph, in which this great authority shows that the apparently large profits on mere drugs are really a reasonable reward for labour and skill.

There is too much reason to think that these elementary principles are forgotten by many, not of the poorer classes alone, who would reduce medical remuneration to a degrading pittance, that neither recognises actual outlay nor

Digitized by Google

sustains the dignity of a liberal profession. Let us take the case of an accoucheur. Are we to rate his value at the cost of the timely dose of ergot which he administers? Such a question has only to be stated to carry its own refutation. Clearly the remuneration of his services should be such as to cover the outlay on his past education, and to stimulate him and enable him to regard his life as a continuous piece of high educational work, and his profession as the most responsible which a human being can undertake—more responsible and important in the case of him who practises among the poor than of him who attends the rich, for the simple reason that the rich can multiply their advisers, whereas the poor have to be content with one or with few.

On the delicate question as to whether medical incomes are improving or becoming worse we shall not say much. The letters of Dr. THURSTAN on that subject are not easily to be disproved, in which he reduces the average income of medical men in actual family practice, after deducting working expenses, interest on money spent on education, &c., to little more than £350 a year. The inadequacy of this income is further shown by the scanty savings of medical men, and the slight reserves for a "rainy day" which they are enabled to put by. It is impossible that medical men should not suffer in common with others in a time of general depression, such as we are passing through. But Dr. THURSTAN'S complaint goes much further than this, and implies a want of public recognition of the value of medical services. He blames errors of administration in public medical charities, which tend to break down the sense of honest independence among the farmers, tradesmen, and working people, and which infect these classes with a low sense of the value of medical services. "A Hospital Surgeon" in a very able letter in our columns, in reply to Dr. THURSTAN, vindicated young consultants, and described graphically the anxious years of strained hope and patience which they had to pass through before attaining to assured comfort, to say nothing of independence. "An Old Oxonian" did not seriously question Dr. THURSTAN'S facts. He properly complains that old and eminent men should be tenacious of humble appointments, instancing a hospital surgeon who to near his death held many clubs. He admitted that from his neighbourhood several rich people, *far better off than local doctors*, had gone as in-patients to London hospitals. It is, as he indicated, a grievous evil when eminent hospital surgeons admit patients to be treated by them as gratuitous patients who cannot pay their fees, but who can easily pay the fees of highly capable men who have not yet attained that degree of fame which implies the power to command large fees. If young consultants were thus considered a little more by their seniors, they would find an earlier reward of their ardour and study, and would be less open to the temptation to compete with general practitioners. By this as it may, it is a monstrous thing that well-to-do people should be treated gratuitously in hospitals simply because they cannot pay the very highest fees of operating surgeons. After all, the maintenance of a proper standard of fees and of the dignity of the profession rests chiefly with members of the profession itself, rather than with its corporations or the Medical Council. The power of the latter in this regard, is extremely limited. The Corporations have still ethical powers which they do not sufficiently use, and which they should be pressed to employ more frequently when their members forget the obligations of a learned and liberal profession. But, after all, it is to individual members of the profession that we must look—to the older members for a little more consideration for the younger, and to the younger for more regard to the traditions of professional honour and for maintaining the traditional fees, *plus* something that will represent the larger wealth of the public and the larger wants of medical men. Competition is inevitable. With six or seven hundred more entering the profession yearly than are needed to fill natural vacancies, there must be competition. But let it be the competition of those whose wants are modest, and who see in true professional ways the only sure path to lasting success and credit. Even in competition for appointments in which the poor are concerned, nothing is more important than to hold high the value of medical services. The working classes need instruction on this point. It is of more moment to them than to their richer neighbours to have one good medical man, and to retain him by generous treatment.

THE subject of the holidays occupies the minds of a large portion of the inhabitants of this country at present. Boys and girls are looking forward to a delightful cessation from work; more or less anxious parents are forming plans for the amusement and gratification of their children. The cry of "What shall we do with them in the holidays?" is not heard so constantly in the summer as in the winter, since if the weather is at all propitious amusements are comparatively easily obtained, and the young people return to school looking as well as or better than when they left it. Not so, unhappily, in the Christmas vacation, when parties, sight-seeing, and sometimes want of exercise, send them back to school decidedly the worse for their holiday. Crowds of school-boys and school-girls will be congregating at the sea-side during the ensuing months. The question naturally arises how best to employ this time to the benefit not only of their bodies, but also of their minds. The fashion of mixing up lessons and holidays is an undesirable one. Let our children work while they work and play while they play; only it is sometimes necessary to teach them how to play. Of course allusion is not made here to cricket, tennis boating or fishing; but many a boy even with these amusements will give utterance to the complaint some part of the day, "There's nothing to do." A listless mind is good neither morally nor physically, and a remedy for it might be found to lie in cultivating the habit of observation. The seaside would present a far wider field of amusement if parents would endeavour to interest their children in the natural objects round them. Of course this presupposes a degree of intelligence not always found, and even where it is present the habit of indolence too often intervenes. It is a common belief that the mere fact of holidays ought to be all-sufficing to the rising generation, but the active minds and bodies of our boys and girls require constant occupation, and also a change of occupation. In cultivating the love of natural objects, the knowledge of the habits of birds, fishes, butterflies, either at the seaside or in the country, a great stride is made towards dissipating the ennui which sooner or later may attack the young holiday makers. It seems strange that our seaside towns are not more alive to this fact, and

Digitized by Google

that, except in rare cases, no attempt is made by the local authorities to exhibit the manner of life and the habits of fishes and other occupants of the sea. Why should there not be in every such town an institution with an aquarium and a good collection of butterflies, flowers, and other natural objects to be found in the neighbourhood? Our boys would often enter with pleasure into a search if they only knew what to look for. The very pebbles of the beach might be made to furnish amusement if the different kinds were exhibited and catalogued in their rough and in their polished state, especially if facilities for cheap cutting were afforded. Few things are of greater value in many professions than a keen observant faculty, and in most cases it is the result of careful training on the part of parents and schoolmasters, or at a later period of the individual himself. Take, for instance, the medical profession: how much success many a man owes to his keen powers of observation, which materially aid him in diagnosis and treatment. If our boys were taught to use their eyes in connexion with common natural objects, the probable result would be an extended power in other departments. Even more marked benefit is to be looked for in the summer holidays for our girls than for our boys. Boys have their games all the year round at school, but the less fortunate school-girl is restricted to the holidays for the full and complete enjoyment of the use of her limbs. She may, it is true, be able to play tennis during the warmer months, but even then it is by no means the serious business which cricket and football are to a boy. The holidays are necessary for the physical development of our girls. Let them bathe, swim, row, run, and even play cricket as much as possible, without incurring the odium of being "unladylike" or "hoydenish." Young girls and growing girls would make better and healthier women if the holiday time were to them a season of complete open air life, with a sufficiency of active but not too arduous physical exercise.

Annotations.

"Ne quid nimis."

A NEW TEACHING UNIVERSITY FOR LONDON.

THE terms of the draft Charter for a new University, to be named the Albert University of London, and designed to include a district of fifteen miles' radius from Somerset House, have been agreed upon and adopted by the Councils of University and King's Colleges, and will accordingly be submitted to the Privy Council in a few days. The Charter is in its essential features similar to that of the Victoria University.

THE HOSPITAL SUNDAY FUND.

THE Report of the Distribution Committee, adopted on Monday by the Council of the Hospital Sunday Fund for the current year, shows that the total amount available for distribution, after allowing sufficiently for liabilities and the usual current expenses, is £39,125. It will be remembered that the result of the collection last year was a total of £40,300. Of course we could have wished that this Jubilee year had had, in addition to all its glories, the distinction of a huge hospital collection that would reduce, if not extinguish, all the adverse balances of our hospital finances. And that may still be the case. We may not yet have seen the full development of Jubilee liberality. Meanwhile the Hospital Sunday collection of the present year approaches within a few hundred pounds that of last year—the largest result which had been realised since the establishment of the Fund. As far as the collection is concerned, the Jubilee evidently cut two ways. It multiplied the demands made on public generosity in a great variety of directions, and by so much created schemes which competed with the Hospital Sunday collection. But the Council has no reason to complain; it receives a sum second in amount only to that collected last year; it conciliates and combines all classes and all creeds, and, as was well said, it enjoys the unique distinction among benevolent Societies of being allowed to have its headquarters at the Mansion House, and the hearty and potent assistance of every Lord Mayor in succession. Sir Reginald Hanson has been a most ardent and valuable friend of the Fund, and is evidently ready to serve it further in the future, if elected, as he no doubt will be, to serve on the Council.

THE INTERNATIONAL CONGRESS OF HYGIENE.

EVERY State, European and Transatlantic, will be represented at this great hygienic gathering. The Organising Committee have already enrolled the names of 960 members and the "four figures" will be reached, it is confidently expected, before their books are closed. Local committees have been at work in every province of the Austro-Hungarian Empire, and Prague, Salzburg, Laibach, Czernowitz and Lemberg, with Wiener-Neustadt and Kakonitz, have each contributed to the effective force of the Congress. The Medical Faculty of Vienna, with the various professional societies of the capital, are unwearied in their exertions for the convenience and entertainment of their coming guests, all working together with the determination to make the meeting not only more numerous but also more successful than its predecessors. We announced last week that, to the great regret of the central bureau, the Ministerialrath, Dr. Franz Ritter von Schneider, had resigned his post of president, and that Professor Ludwig, Dean of the Faculty of Medicine, had been unanimously elected in his room. Failing health was Dr. von Schneider's reason for declining the laborious duty; but the committee have succeeded in so far inducing him to accept office that he will take part in the proceedings as honorary president. A highly distinguished name will thus be secured for the official staff, and it is possible that the discussions may not altogether be deprived of the presence and participation of certainly one of the most accomplished of contemporary hygienists. As we write, we learn that subtropical hygiene will be represented at the Congress by Dr. Pedro à Pardo, the delegate of the Argentine Republic. Dr. Pardo, for many years the head of the health department in the Buenos Ayres Government, and dean of the Medical Faculty in its university, brings with him high credentials for the effective discharge of his mission.

TYPHOID INFECTION IN MILK.

IN a paper on Typhoid Infection in Milk, Dr. Ali Cohen gives an account of an epidemic in Groningen from Nov. 1884, to March, 1885. The infection was traced to a dairy in the suburbs where two persons had suffered in October from continued fever followed by hypostatic pneumonia. Two others were attacked by undoubted typhoid fever, and died in consequence. At one corner of the dairy there was a manure heap, at another a pump, and close by a watercloset. This latter was used for the patients' dejects. The milk of course was sold in the town, and the water from the pump was used for cleaning the cans and all necessary uses of the dairy. All the cases of typhoid in the

Digitized by Google

town were those of people who bought milk from the dairy. Inmates of houses in which cases of infection occurred who dealt elsewhere escaped. In two cases the disease was induced by water drunk from the pump. A house close to the dairy possessed a pump which gave foul water. Two of the inhabitants, therefore, drank the clearer water of the dairy pump and were attacked, while two others who drank the foul water escaped infection. Forty-six cases of typhoid in the town could be indistinctly traced to the dairy, since no one who purchased milk elsewhere was attacked. Even boiling the milk appears to have been unavailing, as fourteen people who drank boiled milk suffered, and three who took it only in coffee. That the disease was due to the milk is evidenced by the fact that people in different parts of the town under totally different hygienic and social conditions suffered, the only bond of connexion being the milk purchased from the dairy. Dr. Ali Cohen remarks that this is a very weighty point, since in other epidemics of "typhus" due to drinking water most of the patients lived in the same place and under the same hygienic, or rather unhygienic, conditions.

SCIENCE AND RELIGION.

EVERY candid man, whatever his convictions, must sympathise with the purpose of the Victoria Institute, whose primary aim has been to promote the examination and, if possible, the reconciliation of apparently opposite scientific and religious views on questions of common interest. The address delivered by Professor Stokes last Tuesday week in the institute was distinguished by a fairness of argument which was characteristic of this purpose. As he pertinently observed, it is necessary first of all, in order to arrive at a just conclusion from such discussions, that there should be a disposition to follow the guidance of truth wherever it may lead. The effort to do this does not imply merely that supple versatility of intellect which goes with the habit of lightly turning over prevalent opinions without any serious attempt at mental penetration. What it does imply is a resolute and patient sincerity in dealing with facts and opinions from whichever side of the discussion they may come, while admitting for all concerned the possibility of misunderstanding. If arguments of this kind were more often conducted in a dispassionate spirit, we should hear less of the antagonism between science and religion. We will confess that we have no belief in the reality of this supposed antagonism. The conflict, when it arises, is rather between the votaries of one creed or the other than between the creeds themselves. Nor is it found that the best minds engaged on either side are the most bitter partisans. It is not usually the laborious investigator of scientific problems who concerns himself with the disparaging statements of revelation. It is not the man whose chief desire is to model his belief, his daily thought and action, according to the plan of an inspired Scripture who cavils at the honest doubts of the scientific reasoner. In both of these types there is not wanting the charitable fellow feeling which comes of personal sincerity and seeks to promote agreement wherever that is compatible with a conscientious exercise of judgment. Contentions arise much more commonly from the impatience of half-instructed disputants. The unwise immoderation of persons of this class has done much to obscure the harmony naturally existing between the truths of science and those of revelation, a harmony which has been repeatedly denied but never disproved, and which is to-day more widely admitted than perhaps at any former time in the history of this controversy. The address above mentioned was itself a model of reasonableness, and in this respect may serve as a pattern for any who may hereafter discuss from either standpoint the subjects with which it dealt.

THE SANITARY CONDITION OF MARGATE.

MARGATE and its sanitary condition continue to engage public attention, and the Town Council have published a report by Professor Corfield on the mortality returns of the borough during the six months ended June 30th of the present year. The report shows "that the borough has been during the past half-year remarkably free from zymotic disease of any kind"; but no one is content with this fact, if Margate retains conditions which are liable at any moment to be a source of danger to the inhabitants and visitors. A clergyman who visited the town with his children last year writes to the papers that six of his family were ill with diarrhœa within a week, and one lingered on to die on their return home. This death would not affect the Margate rate of mortality; but who can say how many more cases of this kind there may be? Families visiting the seaside for the benefit of their health do not desire to inhale the exhalations from hundreds of cesspools, however much these may be diluted by the sea breezes. Last year showed Margate to be the seat of a considerable prevalence of typhoid fever, and the town still has about it all the conditions to foster this disease. It would be a misfortune if the public mind were quieted before the Town Council have recognised the necessity of performing the most elementary duties of a sanitary authority—viz., the provision of a safe water supply and of a proper system of excrement disposal. As a mere matter of pecuniary investment, the necessary outlay would have an ample return in the security it would give to the health of the many persons who annually frequent this locality. Until the Town Council have fully complied with the recommendations contained in Dr. Page's report to the Local Government Board, and are able to assert that the conditions which are therein properly condemned no longer exist, it is impossible for intending visitors to think of Margate as a town in which proper precautions are taken to secure them from disease.

PHOSPHORUS AND INTELLECTUAL ACTIVITY.

WHETHER the now famous aphorism, *Ohne Phosphor keine Gedanke* (Without phosphorus no thought), originated with Büchner, or, as a recent writer believes, with Moleschott, the phrase has doubtless been dragged into use in a most unjustifiable manner, especially by the proprietors of drinks and nostrums containing, or said to contain, phosphorus, and which are on the strength of this urged indiscriminately on all who have brain work to do, as well as on all who suffer from any affection which tends to impair the functional activity of the nervous system. This, of course, is about as sensible as the celebrated advice to Verdant Green to lay in a stock of "Reading" biscuits to assist his reading. The writer referred to, Mr. Atwater, is positive that Moleschott, in using the phrase, had no intention of stating that there was a definite connexion between phosphorus and thought, but meant to show that thought is a function of organised matter. Agassiz is credited with the responsibility of the theory that fish is a peculiarly valuable food for persons who have to use their brains to a large extent, because of its richness in phosphorus. As a matter of fact, however, M. Atwater has found, from a long series of researches, that fish meat contains no more phosphorus than ordinary butcher's meat, so that the suitability of fish as a diet for brain workers, which is by no means to be disputed, depends rather, as Sir Henry Thompson puts it, on its greater digestibility in consequence of its deficiency in fat than on its possession of an abundance of phosphorus. Reading men, in consequence of their want of exercise, their stooping posture, and their frequent confinement for long periods in close and ill-ventilated rooms, are less able to digest their food than men whose work is of

Digitized by Google

a manual nature and lies out of doors. They are thus liable to flatulent dyspepsia, associated, as Dr. Ralfe has pointed out, with alkalescent urine due to excess of carbonates of soda and potash. Urine of this kind causes deposition of phosphate of lime, and this has led some observers to conclude that it is the brain work which causes the apparent excess of phosphorus in the urine, and which therefore requires a diet specially rich in this element, whereas the phosphatic urine would appear in reality to be only an indicaition of disordered digestion due especially to a want of proper aeration of the blood. The recent researches of Zuelzer and others seem to point to the fact that the excessive elimination of phosphorus by the urine is associated rather with nervous depression than with nerve activity, the phosphorus being retained in the body in the latter instance to supply the waste caused by the increased metabolism.

THE RAILWAY WHISTLE NUISANCE.

BARON DE WORMS has done as much as can at present reasonably be required of him to alleviate one of the lesser evils of city life, by engaging that the Board of Trade will interest itself to ascertain how far the annoyance caused by the whistle of railway trains can be abated. It is perhaps hardly to be expected that the use of this form of signal, in so far as it is deemed necessary, should be dispensed with. When, on the other hand, it is needlessly employed at the caprice of an engine driver—and such a case is not imaginary,—the ears of the public have surely some right to consideration. Nay, we may fairly be allowed to ask if no alternative plan can be suggested to obviate or to render less frequent the necessity for signalling in this way within the walls of railway stations and in tunnels. A shrill steam whistle is capable of injuring the drum of the ear so as to cause deafness, and the risk of this occurence is increased when the sound is intensified by concentration within a limited space. It must be allowed that this danger, though real, is not one of great urgency, but its diminution would nevertheless be a distinct advantage. Householders in general assuredly do not, on their part, feel indebted to railway companies, for the signal shrieks which now and then disturb their slumbers, and may even prove so great a nuisance as to compel a change of residence. The sick in particular are much to be pitied when the scanty sleep which is to them a necessity of treatment is thus rudely scared away. It is therefore evidently desirable in the public interest that the use of the whistle should in future be limited as far as possible by some regard for amenities which are now too little considered.

HEPATIC CIRRHOSIS IN CHILDREN.

THAT cirrhosis does happen in childhood is now generally admitted; but the occurrence is still rare enough to make all cases worthy of note. The journal of the American Medical Association reports a paper on the subject read at the meeting of the Association of American Physicians at Washington on June 2nd by Dr. R. Palmer Howard, Dr. S. Weir Mitchell presiding. He reported two cases in which cirrhosis of the liver was present in children, brother and sister. Most unfortunately, the reporter gives no particulars further than saying that sections of the organ were exhibited. Dr. Wm. A. Welch described a case in a child of twelve years. The child had suffered from malaria, and had come from the coast of Africa. Dr. Welch said that most cases of malarial origin had been reported from the coast of Africa. Dr. Forsheimer had seen two cases (one eight years old) which he considered due to syphilis. One, with a distinct history of syphilis, is under observation in the last stage of the disease. Dr. Forsheimer thinks it clear that syphilis is the most common cause of cirrhosis of the liver in children. In the other, at the necropsy the hobnail liver was found. Dr. William Pepper of Philadelphia reported a case in which cirrhosis of the liver followed measles in a child eight years old. During the measles catarrhal jaundice occurred; subsequently the symptoms of developing cirrhosis appeared, and death by coma ensued. The whole duration of the case was not less than a year. At the necropsy a typical hobnail liver was found. Here, then, are six cases of hepatic cirrhosis in children. Though alcohol is not mentioned, it might have been more explicitly excluded. The causation is assigned to malaria, inherited syphilis, and measles.

ADVERTISEMENT IN PRACTICE.

IT is much to be regretted that some cause, probably connected with the still prevailing commercial depression, has, particularly of late years, exposed an ancient weakness in the armour of medical ethics. We refer to the system of trade competition and of self-advertisement resorted to by not a few qualified practitioners. It is needless to say that this custom is not in accordance with a true idea of professional duty. The business of a trade is in itself something different from the practice of a profession, and especially of such a one as medicine. The object of the latter is not merely to make money, but to acquire and apply knowledge for the treatment of disease, and to bear responsibility, such as cannot be appraised in coin alone. It should therefore be evident to most unprejudiced minds that its appropriate methods are not those of the ordinary tradesman. The distribution of handbills soliciting a trial of the benefits to be obtained at some private dispensary and offering treatment at a trivial cost are certainly in strict accord with the usages of the retail dealer, but they convey an unfair and misleading impression of what is really implied in medical attendance. Not only do such practices lower to an absurd degree the public estimate of such attendance, but they offer the unseemly spectacle of a mere trading competition between medical men for the money proceeds of professional service. It has been urged by some that this system suits the pockets of the poor working class. In answer to this argument we might quote innumerable instances in which medical men in general practice have given their best services at little cost without any of the blatant pretension of the quasi-charitable establishments. We might also remind our readers that it is by no means the poor only who avail themselves of the sixpenny dole of advice with medicine which is offered by the latter. Let it not be thought that we dispute the right of practitioners to adjust their fees where necessary to the condition of their patients. It is not the feeling or exercise of consideration in this particular, but the ostentatious advertisement of such consideration with a view to profit that we object to. Some are more tried than others by the temptation to self-advertisement. We have considerable sympathy with young practitioners about to enter general practice as regards this question. Slender means and insufficient introduction are often combined in their case to make rapid success very desirable if not necessary, and to weaken the restraints imposed by professional feeling. We should, however, advise any who are tried not to give way. Success, when it comes, will be better worth having. Practice will be of a superior quality, for it commonly happens that the character impressed upon it at the outset continues with it, and of this the public are not ignorant. With a view to avoidlng the risk of long waiting, and the impatience of scruple which it may entail, one hint may be borne in mind. We allude to the advantage of choosing as a nucleus of practice some spot in the zone of increasing population which invests our cities, or even in a rural district, rather than a long established neighbourhood. In the former there is sure to be some demand for the services of an incoming practitioner such as cannot be counted on in older districts, however

Digitized by Google

populous. By the use of some common shrewdness in this and similar matters, it is still quite possible for young practitioners to exercise their calling profitably without resorting to usages alike unworthy of the practitioner and of his art.

THE HEALTH OF THE POPE.

OUR Rome correspondent writes:—"The sun has entered Leo and the thirteenth Pope of that name abides in the Eternal City when all who can have fled—upper ten thousand, senators, deputies, and *corps diplomatique*. It is the policy of the Curia which keeps the Pontiff immured in the Vatican; but his Holiness accepts the 'situation' with alacrity, and, so far as his health goes, seems the reverse of a sufferer. Much nearer eighty years of age than seventy, he displays an elasticity of mind and a vigour of body which are the envy, if not the reproach, of others far his juniors. This mental and corporeal energy, put forth as it is in a temperature wellnigh tropical, is hardly inferior to that of his middle age, when, as Archbishop of Perugia, he would indite a long Latin epistle in the morning, join a shooting party in the forenoon, and return with the best bag at nightfall, to celebrate the achievement in Ovidian distichs or Catullian hendecasyllabics before retiring to rest. His day begins at 6 A.M., when he rises, takes the cold bath, which he finds so invigorating, and, but for the brief interruption of his slight and admirably regulated meals, works steadily on till late into the evening at his multifarious tasks, theological, diplomatic, and administrative. For the present he is relieved of the numerous and fatiguing audiences which came to an end only last week; but just the other day he presided at the closing ceremony of the Leonine Institute of Literature, and as examiner and adjudicator took for more than three hours the chief part in the proceedings, which he wound up with a brilliant address on the moral and intellectual advantages of an oft-renewed familiarity with Homer, and Virgil, and Dante. To these masters, but mainly to the third, and to his favourite 'Angelic Doctor,' he recurs with enhanced delight now that the ordeal of his Thursday audiences is at an end and his cares are chiefly those of administrative routine. Whether Leo XIII. will see 'the years of Peter,' like his predecessor Pio Nono, or whether he will not, his union of venerable old age with energy of mind and body will long be noted in Pontifical annals, and will in high degree redound, let it also be said, to the skill, the care, and the devotedness of the Vatican medical staff."

A STRANGE CASE.

THE *Retford Mercury* of July 16th contains the report of an inquest touching the death of a young lady aged twenty-six years, a private governess. She was out with her pupils, and after crossing the railway she left the children and returned to the line ostensibly to find a watch she said she had lost. The driver and guard of a passenger train deposed that deceased deliberately laid herself down on the rails, and the jury adopted their evidence, and returned a verdict of suicide. Dr. Savile examined the body after death. He stated that he did not make a *sectio cadaveris*—the coroner did not think this necessary; but from an external examination he obtained no evidence that deceased was pregnant. No motive was assigned for her committing suicide; in fact, at breakfast time on the day of her death she appeared quite cheerful. It seems to us that, as the question of pregnancy was suggested as a possible motive for the fatal act, it was highly desirable that this should have been determined beyond doubt, and that for this purpose a complete post-mortem examination should have been made. The mere mention of deceased being *enceinte*, although unsupported by any evidence and contradicted by some, is warranty enough for a coroner's post-mortem order, for surely, in considering a case of supposed suicide, something is due to the memory of the victim and the feelings of her bereaved relatives. We are not by any means convinced that the death was suicidal. The testimony of the guard and engine-driver was truthful, no doubt, as to observation of facts, but the inference they drew from the facts is open to question. A person seeing a train approaching, and finding himself in imminent danger of death, may become either giddy or fixed trance-like, and unable to make a sufficiently directed exertion to escape the threatened catastrophe. Many such cases have been recorded. Medical evidence on this point should have been given at the inquest.

SANITATION AT LEICESTER.

THE annual congress of the Association of Municipal and Sanitary Engineers was held at Leicester on the 15th, 16th, and 17th inst. There was a large attendance of members, most of whom occupy official positions in various municipal corporations. Amongst the papers read and discussed was "Refuse Destructors for Large Towns," by Mr. C. Jones of Ealing. He described the one erected at Ealing, which had given satisfactory results. Mr. Howson of Leeds referred to the destructors in use at that town, which are situate in a densely crowded locality, and do their work without causing a nuisance. Mr. T. Birch read a short paper on "Sewage Treatment," and criticised some experiments undertaken in connexion with the metropolitan sewage, and the different results obtained with different samples of sewage. The general opinion of the members seemed to be that laboratory experiments conducted on a small scale were entirely fallacious as a guide to practice when enormous quantities had to be dealt with. A paper by Mr. W. Eassie on "Cremation" gave rise to an interesting discussion, many of the members citing instances that had come under observation in their official capacity of the harm arising from earth burial in improper places and crowded communities. This paper was somewhat appropriate for Leicester, as the Town Council has recently had under consideration the desirability of erecting a public crematory, and has gone so far as to get complete plans prepared for the same.

BALDNESS.

A LECTURE on the subject of Baldness, its Causation, and the Rules and Methods for its Prevention, delivered by Dr. Jackson, of New York, has lately formed the text for a variety of remarks in the daily press, with special reference to the increasing tendency to premature baldness amongst men, and to the influence of the prevalent custom of the "morning tub" in bringing about the condition. Premature baldness has no doubt existed amongst mankind as long as records go back, but to what extent it prevailed in past ages, and in different countries, races, and conditions of men, is not very clear, nor are any very trustworthy facts forthcoming for comparison in the present age. However, there seems little doubt that premature baldness is on the increase. Putting aside such forms of loss of hair as depend on definite and well-known diseased conditions, it must be confessed that our knowledge is not very precise as to the cause of the form known as alopecia senilis. The reasons why man should be specially selected, and why the distribution of the baldness should be so peculiar and constant, are problems hard to explain. There is no doubt that premature baldness of this kind is very frequently hereditary, and is entirely a local matter; but where such tendency is present the existence of any local or general disorder readily excites its onset. Some cases also we must ascribe to defective nutrition brought about by actual disease of

Digitized by Google

other parts of the body, by the increased wear and tear of life of the present day, and such-like influences. But there exist still other cases for which it is difficult to assign a cause, and here the action of tight hats in interfering with the local circulation, the continuous wearing of injurious head-gear in destroying the texture of the hair, have been invoked with questionable force. The habit of washing the head each morning and the neglect to replace the oily material is no doubt in time injurious.

"RELATIVE RANK."

THE following remarks from the columns of our contemporary, the *Broad Arrow*, appear to confirm the views we have consistently advanced on the question of relative rank in the Army Medical Service:—"Upon relative rank as such we have had our say. It is not substantive rank, and for the purpose for which it was first instituted it still exists. Upon the proposal to substitute honorary rank for it, we will only observe now that, whilst we suspend our final judgment, we have as yet seen no argument that can commend it to our support. It can add nothing whatever to the dignity and status of medical officers, for it would infallibly expose them, as members of a healing profession, to much captious satire, and its adoption would, we fear, prove a veritable disservice. We confidently believe that, were army medical officers polled, a majority of the best men would be found eager to repudiate every claim to honorary rank, and would declare that the idea is repugnant to their instincts and professional susceptibilities; and, though the voice of these men may not be heard in the prevalent clamour, there is no reason why their existence should be systematically ignored."

THE SMOKE NUISANCE.

THE Select Committee which was appointed to consider Lord Stratheden and Campbell's Smoke Nuisance Abatement Bill has made its report, and has confined its amendments within exceedingly narrow limits, making in effect only one alteration in the proposed measure. That alteration has for its object to place clubhouses, hotels, and refreshment rooms under the operation of the Smoke Acts of 1853 and 1856. The form, then, in which this promising piece of legislative work appears likely to pass the House of Lords will apparently involve us in the most hopeless maze of jurisdictions and authorities. The Bill itself will empower the vestries to impose regulations for the consumption of smoke upon the users of existing stoves, and the Metropolitan Board to lay down rules as to the construction of new grates, thus giving rise to a sufficiently perplexing variety of bye-laws and administrations. But, to make a bad thing worse, the extension of the older Acts will enlarge the sphere of police authority in relation to these matters, so that in the same street there will be three different municipal authorities, administering three different systems of bye-laws, and acting through three different inspectors, to repress the nuisance of smoke contamination of the atmosphere. Surely nothing could be more feeble. If any one of the departments which are thus to be yoked together in an ill-assorted team were set to do this work alone, there would be some chance of its being taken up zealously and done effectively. But when success depends upon concerted action, it is ridiculous to suppose that it can be attained by such an awkward squad as the present proposal will collect. The City Police must co-operate with the Metropolitan Police, and these two again with the Board of Works; and when these metropolitan powers have agreed as to a course of action, they must bring all the vestries within their jurisdiction into co-operation. To organise concerted action on such a scale would demand the genius of a Chatham. The concert of Europe is a simple thing and easily manipulated by comparison. Yet without this concerted action the whole scheme is foredoomed to failure. How can the local vestry visit with penalties the private occupier whose window garden is smirched with soot from the neighbouring chop-house? The exemption of hotels and the like from the present Act is particularly unfortunate, for no restrictions can well be less strict than those of the Act of 1853, to which they are remitted. These buildings are confessedly the worst offenders in the matter of smoke, and the statute law has conspicuously failed in operation to grapple with the nuisance. Therefore these buildings are to be removed from the operation of the new bye-laws and left to the control of the ineffective statute. Truly a wonderful scheme! But let us add a word here. For the glaring deficiencies of this Bill we do not blame its promoters. They have undertaken to make bricks without straw; and though it may be open to a critic to cast doubt on their discretion in so doing, it is hardly fair to complain of the brick-making.

THE BERGEON TREATMENT OF PHTHISIS.

DR. FRANCIS KINNICUTT of New York (*Boston Med. and Surg. Jour.*, July 14th) publishes a brief account of the results he has obtained after a three months' trial of Dr. Bergeon's method of treating chronic disease of the lungs and air passages by means of gaseous enemata. "The apparatus employed was Dr. Morel's of Paris; either the Richfeld springs or the Sharon water, preferably the former, were used to charge the carbonic acid gas (which was freshly prepared for each enema) with sulphuretted hydrogen." Nine cases were so treated, with results which corroborate some of the statements made by Dr. Bergeon. Dr. Kinnicutt says that there seems to be no doubt that the method ameliorates many of the distressing symptoms of advanced phthisis, lowering the pulse, reducing temperature, diminishing the severity and frequency of the sweats, markedly diminishing the amount of expectoration, and improving the appetite. But he has no data as to its capability of arresting phthisis in an early stage. In all the cases the disease was advanced, and in two at least the improvement appears to have been striking. The table of cases includes one of paroxysmal asthma, in which the attacks were completely relieved after a treatment of three days. In the remainder—one a case of pulmonary abscess, another of chronic bronchitis, and the others of phthisis—the treatment was pursued for periods of from eighteen to thirty-nine days. As a contribution to the subject, and an encouragement for further trial of the plan, Dr. Kinnicutt's paper is timely.

CAN IT BE TRUE?

THE *Ilkeston Advertiser* records a case of flogging, the facts concerning which, if correctly reported, are an outrage on humanity. It is stated that a child, aged seven, convicted of the theft of a watch, was ordered to receive four strokes with a birch rod. Our contemporary's report includes a copy of a letter from Mr. John J. Tobin, the doctor called to attend the child after its castigation. It is there stated that the boy was suffering from "lacerated wounds on the side and belly inflicted by the policeman's lash." "The wounds, fifty in number, had penetrated deep into the cellular and muscular tissue; the child was feverish and sickly." The doctor's statement contains the following: "I understand also that the child was arrested and taken out of bed at 1 o'clock in the night, and kept in a solitary cell until bail was given next day." If the above description of the punishment and its effects is accurate we have no hesitation in saying that there is someone who deserves similar chastisement with compound interest. Since writing the above we have been informed that Si

Digitized by Google

Walter Foster, M.P., who saw the child subsequently to the punishment, has interrogated the Home Secretary, and that the latter has undertaken to see "that where there is any doubt about the robustness of a boy's health a doctor shall be consulted before he is flogged." This, no doubt, is an important concession, but it does not affect the question as to the injuries the boy Buckbury is said to have received. It is only just to add that Mr. Matthews, in his reply to Sir W. Foster, stated that the flogging took place "in the presence of the police inspector, his wife, and a Mrs. Knight, who attended at the request of the boy's mother"; and, further, that Mrs. Knight did not think the punishment severe. The flogging took place on the 11th inst., and on the 25th inst. the senior surgeon of the county infirmary examined the boy and reported him quite well. Fourteen days had elapsed between the date of the flogging and the examination made by the infirmary surgeon; and Sir W. Foster, in a letter to a contemporary, says that he saw the unhealed wounds five days after their infliction.

THE PREVENTION OF RABIES.

DR. WHITELEGGE, medical officer of health for the borough of Nottingham, has recently given considerable attention to the subject of rabies in dogs, and has pointed out that in the year ending March last 35 cases of this disease occurred in Nottingham, and 64 cases in various animals within a circle of about five miles around the borough. In 5 cases the diagnosis was verified as the result of inoculation by Professor Horsley of the Brown Institution. Of 49 rabid dogs referred to, 18 are known to have been bitten; the history was also clear in the case of 10 sheep and 2 cows. Of the human beings bitten, six went to Paris to undergo the Pasteur treatment, and in two others cauterisation was employed. One man bitten in the hand, in October, 1886, by a strange dog died in January, 1887, of hydrophobia. A marked reduction in the number of cases of rabies followed the imposition of the muzzle; 243 stray dogs were also destroyed in less than four months. Muzzles can now be used which cause no distress to dogs, and with a view of stamping out this essentially preventable disease their general use should be made imperative.

THE PERMANENT BATH.

SINCE the brief note we published last week upon the alleged value of continued immersion in a bath for the relief of dropsy, we have seen a paper by Dr. James Barr, which will appear in the forthcoming issue of the *Liverpool Medico-Chirurgical Journal*. Dr. Barr gives details of the case of a girl, eighteen years of age, who was in a most critical condition from pyæmia, acute periostitis of the left femur, acute arthritis of the left hip and knee joints, and extensive bedsores. It was decided as a last resource to immerse the patient in a boracic bath at a temperature of about 95°F. For seventeen weeks she was thus kept continuously immersed, with the most satisfactory results. Dr. Barr appends a case of pyæmia treated for four months in a bath by Mr. Chauncy Puzey some years ago. It is evident that the practice is one which might well be more widely adopted, and there does not appear to be any serious difficulty in carrying it out. As Dr. Barr points out, it was a plan long since advocated by Hebra in cases of extensive burn and widespread dermatitis, and at Vienna bath-rooms specially adapted for this purpose are fitted up; but in this country it has been but seldom resorted to, one instance which occurs to us being a case of acute pemphigus, which Dr. Southey brought before the Clinical Society five or six years ago. Dr. Barr's paper is additionally interesting from the description he appends of the "hydrostatic bath" introduced by Dr. Neil Arnott, which consists in supporting the patient (without total immersion) in a bath of water of sufficient depth to permit of it. The description is given in the first edition of Dr. Arnott's famous work on the "Elements of Physics," and it is to be regretted that in the later editions this description should have been curtailed by the editors. The ordinary form of water-bed, although involving less management, is certainly not so well designed for the purpose in view as this very ingenious plan of Dr. Arnott's.

THE GENERAL COUNCIL AND IRREGULAR PRACTICE.

WE would direct attention to an "important notice" which appears on the advertisement sheet (p. 39) of our present issue, in respect of a resolution passed by the Medical Council on April 21st, 1883. The resolution runs as follows:—

"(*c*) 'That the Council record on its Minutes, for the information of those whom it may concern, that charges of gross misconduct in the employment of unqualified assistants, and charges of dishonest collusion with unqualified practitioners in respect of the signing of medical certificates required for the purposes of any law or lawful contract, are, if brought before the Council, regarded by the Council as charges of infamous conduct under the Medical Act.'"

The publication of the resolution at the present time would seem to indicate an intention, on the part of the General Council, to act with vigour in the case of persons whose irregular conduct in the manner specified may be brought under its notice.

SUNSTROKE AND ITS PREVENTION.

SEVERAL cases of sunstroke have recently been reported from the west of England, and intelligence from America shows that deaths from this cause have also been remarkably frequent there. A few observations on this subject should therefore be not unseasonable at the present time. To speak of sunstroke as being due to more causes than one may sound at first sight rather like a contradiction in terms, but there can be no doubt that besides the principal influence at work in such cases there are others of real though secondary significance. In seeking to explain the causation of this morbid state we must, indeed, regard at least two different conditions as commonly acting together to produce the result. One of these is external heat, not necessarily that of the direct solar rays; the other is the presence in excess of impurities in the blood circulation, with a want of due nutrition in the tissues which it supplies. The consequence of this abnormal state of body is necessarily to delay the blood current, and the state of congestion thus engendered in the nerve centres of the brain and cord renders the latter unusually irritable to the action of external stimuli, of which external heat is, for the case we are discussing, the most important. It follows accordingly that prevention must include some care as to modes of living, as well as means of regulating or resisting heat from without the body. For example, the free use of alcoholic stimulants, which tends to impair nutrition, is no longer considered to be advisable; while tea and coffee, which check the formation of waste products, are proportionately valuable. Tight clothing about the chest is generally condemned as being likely to impede the aeration of blood in the lungs, and experience has proved that for a similar reason the imperfect ventilation of workrooms in warm summer weather is conducive to heatstroke. As regards protection against the sun's rays, it should be remembered that not only the head but the back of the neck must be suitably guarded in order to ensure the traveller against the risk of injury. The

Digitized by Google

wearing a damp handkerchief, or a leaf, such as that of the cabbage, next the head has also been found very useful. One word as to the immediate treatment of a case of sunstroke. In some instances doubtless not even the readiest assistance will save life, but in case of need it is well that all should bear in mind that the most effectual form in which first aid can be rendered is the application of cold—as cold water, ice, &c.—to the head and neck.

A SCHOOL-CLOSURE INCIDENT.

A CASE of importance in connexion with school closure on account of infectious disease under the Education Code is likely to come before a superior court. The master of an elementary school at Falmouth, who in January last closed his school on account of measles, under an order of the urban sanitary authority, sought to recover £20 from that authority as compensation. It is well known that such closure involves at times a substantial loss to schoolmasters, and the claim was based on Section 308 of the Public Health Act, which is to the effect that when any person sustains any damage by reason of the exercise of any powers of that Act in relation to any matter in which he is not himself in default, full compensation shall be made to such person by the local authority exercising the powers. But the sanitary authority in this and similar cases acts, not under the provisions of the Public Health Act, but under a code issued by the Education Department of the Privy Council. Taking this view, the magistrates decided in favour of the authority; but at the request of the complainant they have granted a case for the superior courts. We would gladly see the schoolmasters compensated for such cases, and this at the cost of the district for the benefit of which the measure is adopted, but it seems to us doubtful whether the sanitary authorities can in the present state of the law undertake that responsibility.

THE CORONERS' CONSOLIDATION BILL.

THIS Bill, which has been introduced by the Government in the House of Lords, is intended to be simply what its title dubs it—a Consolidation Bill. It is not to make any change whatever in the existing law, and one or two alterations in the letter of existing statutes will serve only to bring the authorities into conformity with what is now established practice. Thus, for example, an old statute of the time of Edward I. requires that a county coroner shall be a knight. This law, though unrepealed, has become quite obsolete, and has long been a dead letter; it is accordingly destined to be quietly dropped. Some half-dozen other similar changes will also be made in the statute-book, but the effect of the Bill will be to gather up and focus in a single document the multifarious law relating to coroners which has now to be picked out piecemeal from two-and-thirty different Acts of Parliament, supplemented by the unwritten "common law."

A BONE-SETTER'S CASE.

IN our last issue we noticed the bone-setter's calling and mentioned one or two instances of egregious blunders committed by quack practitioners. As a sequel the following gives point to our previous contentions. An inquest was held on July 20th at Newcastle touching the death of Joseph Davison, aged forty-two years. Deceased met with an accident which caused a compound fracture of the leg. He was attended to by Dr. Allen, who very properly applied antiseptic dressings. For several days the patient progressed favourably. There was no fever, and the wound remained healthy. Unfortunately for the deceased, he and his friends determined to call in a bone-setter. The latter took off the splint and dressings employed by Dr. Allen, and put on two other splints and applied bread poultices to the wound. Putrefaction set in, and ultimately death occurred from blood poisoning. Dr. Short, who saw deceased subsequently to Dr. Allen's withdrawal from the case, deposed that the bandages were too tightly bound, but that deceased refused to allow him to slacken them. Shortly before death, Dr. McIntyre visited Davison, and found the wound in a putrid condition. The coroner, addressing the bone-setter, told him that, although not guilty of criminal culpability, he was nevertheless deserving of censure for interfering with a case which had already been treated properly and scientifically by a duly qualified medical man. We commend the remarks of the coroner to all those who prefer the services of a bone-setter to a regular practitioner.

NEPHRECTOMY IN BELGIUM.

DR. THIRIAR of Brussels recently performed nephrectomy on a lady patient at Antwerp, this being the first occasion of the performance of the operation in that city. Indeed, it does not seem to have been performed more than four or five times in Belgium. The case was diagnosed as sarcoma, but turned out to be a large renal abscess. The pain had been very severe. Notwithstanding what was said at the Medico-Chirurgical Society on the advantages of the abdominal method, Dr. Thiriar prefers to operate through a lumbar incision. He commences at the inferior border of the eleventh rib at the distance of eight centimetres from the spinous processes of the vertebræ, and, keeping parallel to these, he carries the incision to within a centimetre of the iliac crest, and then, changing its direction forwards, brings it almost to the iliac anterior spine. The external border of the quadratus lumborum is then in view; the attachment of this muscle to the iliac crest is then divided for two or three centimetres, a proceeding recommended by M. Ledentu of Paris, which Dr. Thiriar finds of great value in giving plenty of room for the subsequent steps of the operation.

THE HOSPITAL SATURDAY FUND.

THE Hospital Saturday Fund has issued sheets for use in various establishments for the purpose of promoting weekly or monthly contributions to the Fund. The workshop collections are to be taken weekly till the 3rd of September. This is the right method, as we have maintained; and if it be duly organised and carried out in the various districts and establishments of the metropolis, we may hope to see a very much larger result in connexion with the Fund than has as yet been realised. Much will depend on the co-operation of employers, foremen, and others, which is asked for by the Council, and which we trust will be heartily accorded.

SMALL-POX AT ABERDEEN.

THE small-pox epidemic is spreading and giving rise to considerable alarm. The disease has affected families widely apart, and the efforts of the sanitary officials to stamp it out have not proved so successful as was at first expected. Last week nearly a dozen cases were reported and removed to the hospital. Adults are being revaccinated in large numbers.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—M. Théodore Jouret, member of the Belgian Superior Council of Hygiene, at Kissingen, aged sixty-six.—Don Santiago Ruli, of Barcelona.

Digitized by Google

CHOLERA IN TONQUIN.

THE *Revue d'Hygiène et de Police Sanitaire* states that cholera recently appeared in Tonquin in the form of an epidemic which threatened to assume alarming proportions. Thanks, however, to the prompt and energetic measures taken by M. Halais, vice-resident at Hanoi, who called a meeting of the Sanitary Council, under the presidency of M. Nagier, director of the medical service, and saw that the recommendations drawn up by the Council were carried into effect, the epidemic was almost entirely confined to natives, and was soon stamped out. The measures employed comprised the disinfection of all places where there had been any affected persons or any dead bodies, the establishment of an isolated hospital for natives, the increase of the public pail-closets, disinfection of ponds, ditches, cesspits, and recently disturbed burying places, establishment of new burying places outside the town and under the surveillance of the authorities, careful sanitary inspection of the prisons, restriction of the use of the river water to the Public Works Department and to certain specified localities, inspection of the food on sale, provisioning the country with rice for fear of a famine, and the formation of a permanent native hospital. The ambulance hospital established for the natives is said to have been most successful, fully half the cases which were treated there having been cured.

POISONING BY "LORDS AND LADIES."

TWO children were recently poisoned at Dogsthorpe, Peterborough, as is alleged, from eating some leaves of the plant commonly known as cuckoo-pint, or "lords and ladies" (Arum maculatum). One, a boy aged seven, died after much vomiting and purging within twenty-four hours. We have some doubt whether the *leaves* were eaten, for, as a rule, at this season of the year they have died down, or become shrivelled, leaving a peduncle closely set with bright-red berries. Probably the latter were ingested. The acrid principle, which is destroyed by heat, causes a sharp pricking sensation of the tongue, and in a recorded fatal case the tongue was so swollen that deglutition was difficult or impossible. We are not informed whether any portions of the plant were discovered in the vomited matter in this case.

FOREIGN UNIVERSITY INTELLIGENCE.

Berne.—Dr. Brühl has been appointed *Privat Docent* in Gynæcology.

Bonn.—Drs. T. Rumpf and E. Ungar, *privat docenten*, have been made Extraordinary Professors.

Bordeaux.—M. Coyne, Professor of Pathological Anatomy, has been appointed an Officer of Public Instruction. This appointment is hailed with gratification by the French provincial medical press, which, as a rule, has some cause for its complaint that nearly all the Government distinctions and appointments are monopolised by the Parisian members of the profession.

Breslau.—Professor Emil Richter has been appointed Medical Councillor and Member of the Medical Board of the province of Silesia.

Dorpat.—The assertion of a German medical journal that the professors have refused to lecture in Russian is denied by the *Vrach*.

Göttingen.—Professor Graf Hermann Solms-Laubach will probably decline an invitation to assume the post of Director of the Botanic Institute of Berlin.

Innsbrück.—Dr. Rokitansky, Professor of Internal Pathology, has been appointed Dean for the ensuing year.

Königsberg.—Dr. J. Mikulicz, Professor of Surgery, has been appointed Medical Councillor and Member of the Medical Board of the province of East Prussia.

Leipsig.—Professor W. Pfeffer will next session take over charge of the Botanic Institute, in succession to Professor A. Schenk.

Lille.—To the duties of the Chair of Internal Pathology has been added the teaching of Experimental Pathology. The professor appointed is M. le Dr. Leroy, *agrégé*.

Madrid.—Dr. Don Fausto Garagazza has been appointed Professor of Analytical Chemistry.

Marburg.—Professor Gasser of Bern has been appointed Professor of Anatomy.

Marseilles.—The Chairs of Pathology, Clinical Surgery, and Clinical Medicine are to be filled after a concours to be held at Montpellier.

Montpellier.—M. Gilis, *agrégé*, has been appointed for nine years Chief of Anatomical Studies in succession to M. Chalot.

Paris.—The only candidates for the Chair of Physiology in the Faculty of Medicine, vacant by the death of M. Béclard, are MM. Reynier and Ch. Richet.

Vienna.—Professor E. Ludwig has been appointed President of the International Hygienic Congress, in place of Dr. Schneider who has resigned. Professor Bandl (Gynæcology, &c.) has been refused permission to lecture by the Minister of Public Instruction.

DURING the past six months the Metropolitan Public Gardens Association has received £4337 less than it obtained from the public during the corresponding period of last year. During the four years of its existence the Association has laid out or assisted to lay out forty-three metropolitan gardens and playgrounds, and it is to be hoped that increased and prompt donations will enable it to continue its work, the value of which can only be rightly estimated by those who are brought into daily contact with the inhabitants of the crowded alleys and reeking courts of this modern Babylon.

THE recently issued reports of the Inspectors of Mines to Her Majesty's Secretary of State show that during the past year the aggregate number of persons employed in and about the whole of the mines in the United Kingdom of Great Britain and Ireland amounted to 561,092, of whom 5568 were females above ground. The total number of fatal accidents was 869, and the total number of deaths occasioned thereby 1018; being an increase of 3 in the number of fatal accidents, and a diminution of 196 in the number of lives lost, compared with the totals for the preceding year.

ON the 21st inst. Sir Edward Sieveking presided at the annual distribution of prizes to the students at St. Mary's Hospital Medical School, and at the conclusion of the ceremony was presented by Dr. Broadbent, on behalf of 250 present and past students of the school, with a piece of plate, as a token of their appreciation of his services to the profession and the public and of gratitude for his services to them personally and to the hospital, on the termination of his career in connexion with the hospital school.

M. LABORDE has been elected, by forty-four votes, member of the Section of Anatomy and Physiology in the Academy of Medicine of Paris. His competitors were M. Fr. Franck, M. Gréhaut, and M. Regnard, the first named of whom received thirty-two votes, and the other two candidates one vote each.

THE epidemic of small-pox in Sheffield shows no signs of abatement, fresh cases being daily admitted into the Borough Hospital. Arrangements are being made so that in case of need further hospital accommodation can, by means of temporary iron erections, be provided without loss of time.

Digitized by Google

WIESBADEN in September next will be the seat of the sixtieth Congress of German Naturalists, at which one of the most important features will be the exhibition of scientific instruments. The latest improvements in electro-therapeutic appliances will be on view. Microscopy will also be richly represented; while the assortment of surgical instruments will, it is announced, be the completest yet exhibited.

THE Italian Government has contributed six thousand lire (£240) to the relief of the cholera-stricken at Catania, and the Minister of the Interior has just sent thither Professor Cervello, accompanied by four other physicians, to investigate on the spot the best means of combating the malady.

IN view of the tropical heat now prevailing in Italy, the War Minister has issued orders that the troops, whether in garrison or on service, for the approaching manœuvres, shall be spared as much as possible.

IN the issue of the *Illustrated London News* for the 23rd inst. an illustration is given of the inspection of the Volunteer Medical Staff Corps in the grounds of Lambeth Palace on the 16th inst.

DR. OCTAVIUS JEPSON, on his retirement from the office of medical superintendent of the City of London Lunatic Asylum, after a long period of service, has been granted an annuity of £800.

DR. MORELL MACKENZIE'S book on the Hygiene of the Vocal Organs, which has reached a fourth edition, is being translated into Swedish, German, French, and Italian.

REPORT
OF
The Lancet Commission
ON THE
WORK OF THE PIT-BROW WOMEN OF LANCASHIRE.

THOUGH representing but an infinitesimal proportion of the three to four million women who work for their living, the pit-brow women of Lancashire have recently attracted a very large share of public attention. In 1878 Professor Leoni Levi estimated the number of wage-earning women at 3,800,000. Mr. Atherley Jones, in the House of Commons, spoke of only 6000 pit-brow women, yet this small body of female workers have raised the strongest party feelings concerning their right to labour at the pit brow. The problem involves social, economical, and sanitary issues, and consequently we resolved to undertake a special inquiry. It is only in some districts, notably in the neighbourhood of Wigan, that women are employed at the mouth of the pits; and much has been said both for and against the practice. We can only deal with the social and economical aspects of the question in so far as they bear upon the health of the population concerned; and certainly all these phases of the dispute are more or less intimately related to each other. Through the courteous assistance of the managers, the proprietors, and some of the local medical practitioners, we were able to visit several coal pits, and saw a considerable number of women at work. At the Winstanley pit an engine was placed at our disposal, and thus we got over rapidly the numerous fields that separate one coal mine from the other. While speaking of this pit we must also record that the women work under cover; this is a rare and welcome exception to the general rule.

The work of the women consists, for the most part, in screening the coal. As the little truck or "tub" comes up from the mine, it is seized by a man, who drags it upon the scales, and when it has been weighed places it upon a line. A woman then takes the truck and pushes it along the metals to a tilting machine, ingeniously contrived to empty the contents of the truck on a screen below. This can be done with but little effort. The screen consists of iron bars some twelve to sixteen feet in length, that form an inclined plane. As the coal slides down this screen the slack falls between the bars, and on either side stand women, who with rakes push the coal along, examining each portion as it goes by. If they notice any defect, any slate in the coal, they at once seize the piece, and with a small pickaxe chip off and throw away the useless part. The photograph exhibited in the Strand, and that was given to many members of Parliament, representing this work, shows the women under their most favourable aspect. Here the women are fairly clean and sheltered; in the great majority of cases they are covered with coal-dust, are often drenched to the skin with rain, and very rarely enjoy any shelter whatever. At all seasons of the year they have to stand by the screens, waiting for the coal; and periods of inactivity following on excessive physical exertion must, in wet weather, occasion chills which none but the strongest can endure with impunity. Nor is the work always limited to what we have just described. The coal very frequently is not screened, but piled up in the form of a large embankment. On the summit is a truck rail; women push the truck to the end of this line, and there, without the assistance of any tilting machine, lift the truck bodily up and throw it over. At one mine, where this was done in our presence, the trucks weighed 3 cwt., the coal they contained from 6 to 7 cwt. To lift and tilt these trucks over, it is necessary to stoop so as to bring the hand right underneath and within a distance of from eight to ten inches from the ground. Nor is this all: the metals placed on the loose coal that forms the embankment rest on a very insecure foundation, consequently the truck often runs off the line, and its little wheels sink deep into the coal. The effort necessary to lift up the truck steadily so as not to spill the coal it contains, and place it back again on the line, requires very great strength of muscle. Mere brute force with little or no skill is brought to bear. At one pit we saw a truck come off the line twice before it could be wheeled to its destination. Here some five or six women were at work with one man to help them; and we failed to notice any difference between the man's work and that of the women. They all mutually helped each other, and the women seemed quite as strong as the man. One of the women even offered to wager that she would lift as heavy a shovelful of coals as any man in the mine. The work of piling up the coal is also done in the open air away from all shelter, and the same may be said concerning the women who go on the top of railway waggons to smooth out and pack the coal on the summit so that it should not fall on the line when the train is in motion. Altogether, in many hundreds of employments, men do not perform work of so masculine a character as that of the pit-brow women.

It does not, however, follow that the work is unhealthy. The medical men whom we were able to see at Wigan all bore testimony to the remarkable strength and healthfulness of the women employed at the pit-brow. Certainly those who did not possess good constitutions could not stand the exposure; but such exposure, if it can be endured at all, must have a hardening effect. Many women who had been accustomed to the open-air work could not bear the confined atmosphere of a factory; and, after trying to earn their living at a mill, gladly returned to the pit-brow. On all sides, it is energetically denied that the health of the women suffers. When we inquired into the condition of the dust-yards of London we were told the same thing. The poor, half-starved, ragged women who, for the smallest pittance, sift the dust and refuse of this great metropolis, were all stated to be free from disease. Surprise is also often expressed at the healthfulness of the men who clean out the sewers, and of the staff employed to fumigate and wash rooms after cases of infectious disease. Nevertheless, and in spite of immunity from disease, no one would care to maintain that these various employments are healthy in themselves. But with regard to the pit-brow women, there is no doubt that the open air, in spite of the wet and cold, is a compensation for a multitude of hardships. The trucks, tubs, or boxes, as they are called, weigh from

Digitized by Google

2 cwt. to 4 cwt., and contain from 3 cwt. to 6 cwt. of coal. Though the pit-brow women are represented generally as working at the screen, we are assured on good authority that 50 per cent. among them manipulate these heavy trucks. Fresh air and long custom may give them exceptional health and strength; but it cannot be right for women, at least during the period of child-bearing, to even assist in raising such loads from the ground. The working at the screen, on condition that proper cover be provided, is doubtless more healthy than working in a badly ventilated factory. This is a strong argument in favour of the better ventilation of factories, but that does not prove that women can with impunity and all times and seasons do men's work. With still greater force do all these arguments apply to young children. What may be said concerning a fully developed and strong woman cannot be maintained with regard to a young and unprotected child. Yet we have seen children working at the pit brow; one whom we questioned was under fourteen years old; she wore male attire, and was lifting and chipping heavy and very large pieces of coal. Mr. M'Laren declared, in the House of Commons, that there were only some 300 children between thirteen and sixteen working in connexion with the coal mines. If the number is so small, it would inflict no great social hardship to establish by their exclusion the principle that the healthy development of the new generation is the first of all considerations, and that, when such vital interests are at stake, the State has the right to interfere.

Much has been made of the peculiar dress the women wear. The bodice is that of an ordinary working woman's jacket fitted over a common pair of stays; for, in spite of the stooping, most of the women wear stays. The legs are covered with a cast-off pair of trousers, obtained from some male relative or friend. These garments are patched with many colours; and the idea of women wearing men's old trousers certainly does not lend itself to romance. Second-hand clothes, we have always objected, may be the means of conveying infection; but we can scarcely blame poor people for resorting to such economies. Putting this latter question aside, it cannot be said that the women are indecently dressed. They are more securely covered than if they wore skirts, and better able to defy the rude aggression of the wind. With their blackened faces and clothes they are scarcely recognisable, and their appearance is hardly likely to suggest any impropriety. In respect to general decency, the want of proper closet accommodation is of far graver importance. The closets, of the midden type, are out in the open, removed from all dwellings, and clean; but the number was altogether insufficient, and the separation between men and women of a purely fictitious character. The women earn about ten shillings a week; this gives them a certain independence. They have little or no social status to maintain. Among the working classes they are contemptuously called *canacks*, and rarely marry other than collier lads. The working-men miners, with whose representatives we have discussed the question at length, unanimously demand the suppression of the work of women at the pit brow, not because the work effects the health of the women, but because it destroys the homes of the men. The women are not domesticated; they cannot cook a decent dinner; when they are married their husbands do not stay at home, as there are but few comforts to greet them, and this leads to intemperance. The children also are grievously neglected, and the natural result is a deterioration of public health.

Mr. Barnish, the medical officer of health of Wigan, in a lecture delivered a year or two ago, showed that, while the death-rate of England during ten years previous to 1883 amounted to 21·4 per 1000, the death-rate of Wigan during that same period was 27·0 per 1000. At the same time, during these ten years the illegitimate birth-rate for all England amounted to 4·9 per cent, while the illegitimate birth-rate of Wigan reached the high figure of 9·2 per cent. Indeed, the work of women at the pit brow is so far discredited among the working classes themselves, that Mr. Abraham, who in the House of Commons was able to speak in the name of the miners, pointed out that during the last twelve years their number had decreased from 6899 to 4131.

In face of all these circumstances, and if the presence of women at the pit brow is still to be tolerated at all, the State should, at least, exclude all children, and all girls who have not reached the age of puberty. The provision of means of shelter from the rain should also be made compulsory, and certainly an increase in the number of closets is demanded, as well as the placing the women's closets in a totally different part of the premises to those used by the men. Women during the period of utero-gestation and lactation might, with advantage to the future generation, be excluded from the works. With these restrictions, which we bring forward as the minimum justified by the case, the greater evils would be dispelled; and doubtless the moral pressure of the community at large, and of the mining population in particular, will soon still further reduce the number of women working at the pit brow.

KAKKÉ, OR JAPANESE BERI-BERI.

No. II.

How far the teachings of Mr. Takaki's experiment go beyond the settlement of the kakké problem is indicated by one of his tables, which, we hope, will be expanded and analysed at some future time. By this it is shown that the daily average of the men sick from all causes in each 1000 of the force was reduced under the new dietary from 121·15 in 1883 to 84·45 in 1884, and 52·25 in 1885; and that the annual ratio of cases of sickness for each 100 of strength fell from 323·54 in 1883 to 186·37 in 1884, and 99·25 in 1885. The most astonishing improvement is in kakké, which fell from 27·30 per cent. to 0·59 per cent., but it was strongly marked in all other important directions. Thus "constitutional diseases" sank from 16·58 per cent. to 7·89 per cent., diseases of the eye from 29·75 per cent. to 7·57 per cent., diseases of the respiratory system from 75·07 per cent. to 18·05 per cent., diseases of the digestive system from 83·38 per cent. to 17·99 per cent., and diseases of the integumentary system from 28·85 per cent. to 8·22 per cent. Genito-urinary diseases alone maintained the former level, but this exception only emphasises the significance of the other facts.

These statistics, after all allowance has been made for improvements in general hygienic conditions, place it beyond doubt that Mr. Takaki has achieved a success of very large proportions, and one which hereafter will prove to have a far wider range than has yet been demonstrated. It is probable that his theory will require modification; that error of diet will be admitted to occupy the second place instead of the first in the order of causative agents; but the fact will still remain that by a measure initiated by himself, and carried out with all the courage of a strong conviction, he has been able, not only to quell within the sphere of his action a malady which had baffled all the efforts of his predecessors, but he has shown his countrymen how they may fortify themselves against disease in general, and hope for a progressive augmentation of physical development and vigour.

The dietetic theory of the origin of kakké is not a new one, but it has never before been supported by material facts. The majority of observers of the disease have been inclined to attribute its existence to a specific poison which is generated in the soil under certain insanitary conditions of local origin, and finds its way into the human body by means of the atmosphere, and perhaps of the food and drinking water also. There is certainly much in common between kakké and complaints generally recognised as miasmatic, although the former presents no clinical resemblance to ague or its immediate allies. It has been stated without contradiction that kakké is particularly liable to develop in low-lying and ill-drained districts, and under circumstances of overcrowding. It prevails during the hot, rainy season, and is rare in the dry, cold winter months. Its attacks are directed chiefly against male adults in the prime of life, and are very seldom met with before puberty or after the age of forty-five, while the susceptibility appears to be ten times greater in men than in women. New arrivals in a kakké district are especially predisposed, and suffer more severely than the natives and older residents of the place. It is non-contagious; and, lastly, one attack affords no protection against a recurrence. It is, however, distinguished from typical maladies of the malarious group by the absence of febrile disturbance and periodicity, and by the prophylactic and therapeutic inefficacy of arsenic and quinine. Mr. Takaki, indeed, uses the latter fact as a weapon against the miasmatic theory, and says that "if malaria be the cause, quinine

Digitized by Google

should have a specific influence over it, while the peasants who are constantly breathing a malarious atmosphere should be more especially attacked by the disease, but there is no positive evidence to this effect." But this argument contains a double fallacy, since it assumes that there is only one kind of miasmatic poison, and that all the various manifestations of malarious disease are necessarily amenable to the same remedy.

If, on the other hand, we endeavour to look upon kakké as a disease of malnutrition, it is not easy to discover any analogy between it and the conditions known to arise from the privation of essential elements of food. The most fatal attacks may occur in subjects of more than average vigour, and, as pointed out ten years ago,[1] and since repeatedly confirmed, anæmia and physical enfeeblement are far from being necessary concomitants. It may also be remarked that the use of a dietary containing a relatively small proportion of nitrogen is not confined to kakké and beri-beri countries, and that in India Europeans under a European scale of diet may suffer severely from beri-beri when living in a district where that complaint is rife amongst the natives. It is of course possible that some of these facts are open to a different explanation, and that others may be contradicted altogether when new information is forthcoming, but for the present the weight of evidence is still in favour of the miasmatic hypothesis. We may, however, regard it as proved by the extraordinary results of the naval experiment that an imperfectly nitrogenised food exerts an especially powerful influence upon the prevalence and intensity of the disease, and that the system may be strengthened against attacks by a diet scale constructed in accordance with European theories of nutrition.

Since the study of bacteriology has gained ground, many observers have looked for a solution of the mystery in the detection of a specific micro-organism in the blood and tissues of affected subjects, and already a claim to success in the research has been advanced by two physicians, Dr. Wallace Taylor of Osaka, and Dr. M. Ogata, of the Tokio University. Dr. Taylor (Transactions of the *Sei-I-Kwai*, August, 1885) states that he has found in the blood and urine of persons suffering from kakké, and also in the soil and canal water of infected districts, and in the rice used as food, a spirillum by means of which after cultivation and inoculation he has been able to produce the symptoms of kakké in the hare, monkey, and rabbit. He finds, moreover, that the organism is not destroyed either in the process of cooking the rice with which it is associated, or by the digestive secretions after it has entered the alimentary canal. Dr. Ogata, after a similar course of investigation, has described a specific kakké bacterium in the blood, and asserts that he has succeeded in conveying the disease to monkeys, dogs, rabbits, and pigeons by inoculation, and to monkeys and dogs by simple admixture of the virus with the food. He has also extracted from the blood of persons who have died from the complaint an acid substance which, by inoculation, induces in the rat a train of paralytic symptoms like those of kakké.

These observations, supported as they are by similar discoveries at the hands of investigators of beri-beri in other countries, are highly suggestive; but until the experiments are reported in greater detail, it will be impossible to judge as to their freedom from sources of fallacy, or to see how far the differences between the two sets of results are capable of reconciliation. It is especially necessary that we should know upon what evidence the two pathologists have assumed that the symptoms caused by the inoculation of the germ into the lower animals are identical with those of kakké in man, for a mere superficial resemblance would be quite inconclusive. Dr. Taylor's discovery of the beri-beri spirillum in canal water and rice, taken in conjunction with Dr. Ogata's assertion that in dogs the virus is efficient when merely swallowed with the food, would lead us to think that the disease must prevail amongst the canine race independently of the intervention of the bacteriologist but it is not known that this is the case.

In conclusion, we may be allowed to remark that neither the etiology nor the intimate pathology of kakké has been removed from the stage of speculation. The necessary inquiry into the conditions under which the complaint is developed in various parts of Japan have not yet been sufficiently carried out, and the pathological researches are in need of confirmation and extension. The problem, however, has been attacked with good will and intelligence from two sides, and Mr. Takaki may already be congratulated upon the magnificent and unassailable results attained by his dietetic experiments, results which alone are sufficient to entitle him to the gratitude of his countrymen and the esteem of his profession.

For the benefit of those who are interested in the subject, a list, arranged in chronological order, is appended of the literature at present accessible to Europeans with respect to kakké:—1. "Kakké," by Dr. Hoffmann of the Imperial Medical College in Tokio, published in the Transactions of the Deutsche Gesellschaft für Natur und Völkerkunde Ostasiens, July, 1873. 2. "Kakké," by William Anderson, F.R.C.S., St. Thomas's Hospital Reports, vol. vii., New Series, 1876. 3. "Klinische Untersuchungen über die Japanische varitäl der Beri-beri Krankheit," by A. Wernich, M.D., Virchow's *Archives*, 1877. 4. "Lectures on Kakké," by William Anderson, Yokohama, 1879. 5. "Beri-beri, or the Kakké of Japan," by Duane B. Simmonds, M.D., Medical Reports of the Imperial Maritime Customs of China, 1880. 6. "Beri-beri, or the Kakké of Japan," by Stewart Eldridge, M.D., *Pacific Medical and Surgical Journal*, Dec. 1830, and Jan. 1881. 7. "Die Japanische Kakké (Beri-beri)," by B. Scheube, M.D., *Deutsche Archives f. Klin. Med.*, 1882. 8. "Kakké," by Theobald A. Palm, M.D., *Edinburgh Clin. and Path. Journal*, Sept. and Oct. 1884. 9. "On the Cause and Prevention of Kakké," by K. Takaki, F.R.C.S., *Sei-I-Kwai Medical Journal*, April, 1885. 10. "Pathology of Kakké," by Wallace Taylor, M.D., *Sei-I-Kwai Medical Journal*, Aug. 1885. 11. "Kakké amongst the Japanese Maritime Prisoners," by K. Takaki, F.R.C.S., *Sei-I-Kwai Medical Journal*, April, 1886. 12. "The Circulation in Kakké," by Wallace Taylor, M.D., *Sei-I-Kwai Medical Journal*, July, 1886. 14. "First and Second Special Reports upon the Improvement in the Scale of Diet in the Imperial Japanese Navy," 1887. 14. [1] On Kakké, St. Thomas's Hospital Reports, 1876.

ETIOLOGY OF SCARLET FEVER.

AT the meeting of the Edinburgh Medico-Chirurgical Society held on July 20th, for the discussion upon Scarlatina, T. Grainger Stewart, M.D., President, in the chair, an interim report of the committee appointed to inquire into the results obtained by Mr. Edington in his research upon the Etiology of Scarlatina was read as follows:—

"Your committee reports that, in accordance with instructions received, an inquiry and experimental investigation has been commenced with regard to the results obtained by Mr. Edington, M.B., and published in his paper entitled 'An Investigation into the Nature of the Contagium of Scarlet Fever.' It will be evident to the Society that sufficient time has not yet elapsed for your committee to have formed a definite opinion upon the intricate and important issues raised; many of the experiments are still in progress, while the number completed is too limited to warrant a distinct conclusion. Before detailing the lines adopted in the inquiry, the committee has to record its appreciation of the courteous co-operation of Mr. Edington in supplying information and affording facilities for the furtherance of the work. So far as your committee has been able to judge from inquiry and observation, Mr. Edington appears to have followed carefully the recognised methods of bacteriological investigation, and to have observed the precautions necessary to ensure accuracy in his laboratory work. Evidence has, moreover, been afforded of the large amount of laborious and long-continued work which his research has involved. While it is impossible in the meantime to report definite results, it appears desirable that the Society should be made acquainted with the general line adopted in the inquiry. This has included the consideration of the following points among others:—1. A preliminary inquiry with the object of defining accurately the conditions observed by Mr. Edington in his research. 2. An inquiry into the characteristics and the specific value of the several organisms which Mr. Edington has separated and described, with inoculation experiments on healthy animals. 3. The repetition of Mr. Edington's observations, including the microscopical examination of scarlatinal blood and desquamation, cultivation experiments with the same materials, and a collateral series of observations on the healthy subject to

Digitized by Google

control the results obtained. In the further prosecution of the inquiry, the committee will be much helped by the co-operation of the members of the Society, in giving them access to early cases of the disease suitable for experimental investigation; especially to such as are in the earliest stages of the fever, or such as may be deemed to be in the period of incubation.—On behalf of the committee,

"(Signed) T. GRAINGER STEWART, convener."

In the absence of Dr. Brakenridge, who was expected to have opened the discussion, the President called upon Dr. Jamieson to do so.

Dr. Allan Jamieson described the general characters of the recent epidemic in Edinburgh, which, although it has been very extensive, has not been of a very virulent type. Accurate observations have been made at the City Fever Hospital with regard to the incidence and relative intensity of the several symptoms and complications of the disease. It is found that nephritis is commoner in cases of distinct milk infection than in those where infection is derived from other sources. The temperature reaches its maximum on the second or third day of the disease, and desquamation, which is invariably present, commences from the fourth to the sixteenth day, on the tenth in the majority of cases. Desquamation is usually profuse after a well-marked rash, but this association is not invariable. As regards complications of the disease, out of two hundred cases specially recorded, thirteen had rheumatism, thirteen glandular enlargements in the neck, seven nephritis, four diphtheritic sore-throat, and four inflammations of the ear. The primary sore-throat always precedes the occurrence of the rash. In speaking of the etiology of the disease, it must be noted with what great rapidity the contagium can multiply; in this, however, it does not equal the contagium of typhoid fever. The disappearance of the bacillus from the blood at an early stage, as seen by Mr. Edington, is the most natural thing to be expected of it, when it has exhausted the papulum suitable for its maintenance at the crisis of the disease; such behaviour on its part is quite comparable to that of the embryos of filaria. In the treatment, boroglyceride is applied to the throat, and antiseptic mouth washes are used. Warm baths are also employed throughout the treatment, the bath being wheeled to the bedside and the patient placed in it and lifted out again without any change in his posture. Salicin acts efficiently in alleviating the rheumatic complications, and cotton wool, iodine, and iodide of potassium in checking and causing resolution in the cervical glandular enlargements. In the matter of prophylaxis, Dr. Jamieson was not desirous of claiming originality in drawing attention to the treatment by inunction. The method was an old one, but what he did draw attention to as of importance was that the antiseptic should be applied all through the disease, so that the spores of the causative organism, which he believed were deposited in the deep layers of the rete Malpighii, might be destroyed and prevented from ripening in the epidermis, and thus becoming a source of infection. A very important point is the frequent washing of the scalp with carbolic lotion, as the branny scales from this region are specially dangerous as a source of infection. During the recent epidemic there had been 500 cases in the hospital, and they had experienced a mortality of 3·6 per cent. among these patients.

Mr. Edington gave further information than was published in his original paper, as to the size, character, and method of growth of the bacillus separated by him, and described as the cause of scarlatina. Its length, which had been understated, varies from 2·5 to 4·5 μ. In a series of subcultures there is a marked increase in its rate of growth, specially if these subcultures be plate cultivations. In regard to the appearance of the bacillus in the skin not earlier than the twenty-first day, there was no doubt of the fact; and the large number of cases where it had been sought for earlier without result were sufficiently extensive control experiments, the absence of which had furnished ground for some criticism. He showed the appearance of a colony from a plate cultivation by a photographic transparency and the oxy-hydrogen light.

Dr. Foulis traced very carefully the history of the Edinburgh epidemic, and showed that of 597 cases of scarlatina in the month of February 200 cases had received their milk supply from eleven dairies, all of which obtained milk from farms supplying 120 gallons per diem, where there was a distinct source of contamination in the form of severe cases of the disease. A chart thrown upon the screen with the lime-light gave interesting evidence upon this point, showing the localities specially affected in the outbreak. Dr. Foulis urged strongly the necessity of compulsory notification of disease in rural as well as in urban districts, as the only way of preventing such outbreaks.

Mr. Hare spoke of the ways in which a milk supply may become a source of infection. That direct contamination from the human subject was one method was placed beyond reasonable doubt by the Transactions of the International Medical Congress in 1881. These records, however, showed certain cases, no less than five epidemics out of the sixteen described, where the human origin of the infection was not clearly established, and where other factors might be at work. But it was the recent work of Mr. Power and Dr. Klein which had rendered it all but certain that in some cases at least the infection was of bovine origin. The speaker then gave a *résumé* of Mr. Power's paper and of Dr. Klein's experimental results, and demonstrated a series of cultivation and microscopical specimens illustrating Dr. Klein's work, and lent by him for that purpose. He also referred to the question of disinfecting milk by heat, speaking of the difficulties experienced by bacteriologists in rendering it sterile for experimental purposes, and the degree of heat necessary to do so. If the contagium of scarlatina has as low a death temperature as that described by Klein, this difficulty would be obviated; but in any case the only efficient method to employ was to prevent infection at the source of milk supply, and not to attempt its destruction when conveyed to the consumers.

(To be concluded.)

THE HYDROPHOBIA QUESTION.

M. LUTAUD, the editor of the *Paris Journal de Médecine* and author of a severely critical work ("M. Pasteur et la Rage") upon the Pasteurian treatment of hydrophobia, delivered a lecture on this subject on Wednesday last at Prince's Hall, Piccadilly, Lord Henry Bruce, M.P., in the chair. The lecture was delivered in English before an audience of about 200 ladies and gentlemen. M. Lutaud commenced by criticising the report of the English Commission, which he characterised as confused and inconclusive. He pointed out that the comparison made in that report between vaccination and Pasteur's method was incorrect, seeing that the former was prophylactic and the latter alleged to be curative. The Commission had personally inquired into 90 cases treated by M. Pasteur, but only 24 of these were said to have been bitten by undoubtedly rabid dogs, so that the 8 fatal cases in this number were far in excess of the usual proportion of fatalities in cases of bites of rabid dogs—viz., 5 per cent. The report had reckoned that of the 2682 cases treated at the Pasteur Institute the mortality should have been 130 instead of 40, but it ought to have been stated that only 233 of the cases were found to have been bitten by rabid animals, which should have given only a mortality of 15 if untreated. M. Lutaud contended that the Pasteurian method had increased the mortality instead of diminishing it. Before its adoption the annual average mortality in France was 30. In England and Wales the average is 43, in Austria 12, whereas in Germany for the past two years not a single case has occurred. The actual mortality in France during 1886 was 42, of which 25 had been treated by Pasteur. The introduction of the "intensive method" was alleged to have been the cause of 9 of these fatalities from paralytic rabies, and the two English cases mentioned in the Commissioner's report were detailed. M. Lutaud firmly believes that had the man been promptly treated in England before being sent to Paris, he would have been still alive; and the other case—in which the cause of death was said to be pneumonia,—was, he felt convinced, one of paralytic rabies, of which pneumonia is a feature. He concluded that the intensive method was responsible for these fatalities. Professor Horsley's experiments were inconclusive; and, indeed, all experiments where the protective inoculation is practised *before* the introduction of the virus direct, are not comparable in their results with the practice on the human subject, where the inoculation is performed *after* the virus has been introduced. The report of the English Commission had been welcomed by Pasteur's adherents as a favourable support to their views, but yet the Commission did not venture to suggest the free adoption of the method,

Digitized by Google

and to advocate the foundation of a Pasteur Institute in England. Their conclusion in favour of increased police regulation was not based on the results of Professor Horsley's experiments, but on the dictates of common sense. The lecturer solemnly declared that M. Pasteur's method was based on inaccurate experiments and fallacious conclusions, and that the method must be condemned in the interests of humanity and of science. The lecture, which was clear and concise, was frequently applauded, and a vote of thanks was heartily accorded to M. Lutaud and the chairman.

THE HOSPITAL SUNDAY FUND.

ON the 25th inst. a meeting of the Council of the Hospital Sunday Fund was held at the Mansion House to receive the report of the Committee of Distribution. The Lord Mayor presided, and among those present were Sir Sydney Waterlow, Sir J. Risdon Bennett, Dr. Sedgwick Saunders, the Rev. Canon Nisbet, Mr. Joseph Fry, &c. The total amount received this year was only a few hundreds less than that realised in 1886. The report stated that the committee recommended the payment of awards to 158 institutions, being an increase of 4 since last year, and of 53 since the first awards were made in 1873. The total amount available for distribution, after allowing sufficiently for liabilities and the usual current expenses, was £39,125. Of this, the sum of £37,525 was recommended to 108 hospitals and 50 dispensaries. Four per cent. of the total collected—viz., £1600—was set apart to purchase surgical appliances. The following were the principal awards:—Charing-cross Hospital, £939 11*s.* 8*d.*; King's College Hospital, £1354 3*s.* 4*d.*; London Hospital, £3333 6*s.* 8*d.*; Royal Free Hospital, £885 8*s.* 4*d.*; St. George's, £1875; St. Mary's, £1822 18*s.* 4*d.*; Middlesex Hospital, £1979 3*s.* 4*d.*; University College Hospital, £1510 8*s.* 4*d.*; Westminster Hospital, £987 10*s.*; Hospital for Consumption, Brompton, £1675; and Hospital for Sick Children, Great Ormond-street, £729 3*s.* 4*d.*

Sir Sydney Waterlow, in moving the adoption of the report and the payment of the awards, expressed the gratitude of the Council to the public for the increased contributions which had been given to the fund this year, especially considering the very numerous demands which had been made everywhere in this Jubilee Year. He proposed to ask the Council to authorise the distribution of £1100 more than last year. That sum would enable them to distribute on the basis of last year, although they had to include this year four more institutions, making a total of 158, among which the money had to be divided. They had also to set aside a sum of £1600 for surgical appliances, and it was gratifying to know that in this branch 1450 cases were relieved last year, at an average cost of just over £1 a case.

Mr. Joseph Fry seconded the motion, which was carried unanimously.

Resolutions were afterwards adopted conveying the thanks of the meeting to the chairman and other members of the Distribution Committee for the great labour they had undertaken, to the Lord Mayor for presiding over the Council, to the Duke of Cambridge and other noblemen and gentlemen for pleading the cause of hospitals during "Hospital Week," and to the editors of newspapers and other members of the press who had given valuable assistance.

TESTIMONIAL.—An illuminated address, with silver bowl and candlesticks of the value of £70, and a purse of 100 guineas, have recently been presented by Sir Lionel Darell, Bart., to Mr. Thomas Watts, of Frampton-on-Severn, on behalf of his old friends and patients, "as a testimony of their high regard and esteem for him personally, and in recognition of his kind and skilful attention to all who have been the subjects of his professional care during his practice amongst them for upwards of forty years." It is interesting, in relation to this, to recall the fact that nearly fifty years ago Mr. Watts's father, who then held the same practice, had given to him a complete silver tea service, and that on his death, a few years later, a sum of £300 was subscribed to found a "Watts" prize at the Medical Benevolent College. It would be pleasant indeed to believe that characteristics so helpful and so honourable to patients and doctors alike might be considered as capable of hereditary transmission and contagious extension.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF THE INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

The Sanitary Condition of Cranbrook, by Dr. AIRY.—Cranbrook, in Kent, is the centre of a rural sanitary district which is essentially uninteresting from a sanitary point of view, except in so far as it has long been in a neglected state. Dr. Airy's report tells of watercourses polluted with accumulations of offensive filth, sewers broken and riddled with rat-holes, wells of doubtful purity, and such-like matters. Some of the sewage arrangements that have been contrived often cause nuisance at the outfalls; and at Frittenden a prevalence of enteric fever in 1886 was associated with excremental nuisances and polluted drinking water. But the worst of all is the fact that, notwithstanding these circumstances, Dr. Airy gathers, as the result of his conferences with the local people, that, so far as Cranbrook itself is concerned, there is very little hope of any thorough remedy being applied. Unfortunately there is throughout the district a great unwillingness to incur any expense which will show itself in the form of a sanitary rate, and so far such work as scavenging, &c., is alone to be hoped for. There are many people who, seeking rest and health, turn to Kent as the "garden of England." They had better direct their steps to such parts of the county where obvious conditions of ill-health do not prevail.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5980 births and 3937 deaths were registered during the week ending July 23rd. The annual rate of mortality in these towns, which had increased in the preceding four weeks from 17·6 to 20·7, further rose last week to 22·2. During the first three weeks of the current quarter the death-rate in these towns averaged 20·8 per 1000, and was 0·4 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 11·7 in Derby, 13·2 in Portsmouth, 14·3 in Blackburn, and 15·0 in Brighton. The rates in the other towns ranged upwards to 24·9 in Newcastle-upon-Tyne, 27·2 in Birkenhead, 32·4 in Leicester, and 36·7 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 486, 673, and 880 in the preceding three weeks, further rose last week to 1173, owing to the increased mortality from diarrhœa; they included 800 from diarrhœa, 162 from whooping-cough, 100 from measles, 54 from scarlet fever, 29 from diphtheria, 27 from "fever" (principally enteric), and only one from small-pox. These zymotic diseases caused the lowest death-rates last week in Halifax, Derby, and Brighton, and the highest rates in Leeds, Preston, and Leicester. The highest death-rates from diarrhœa occurred in Nottingham, Liverpool, London, Leeds, Preston, and Leicester; from whooping-cough in Bradford, Bolton, and Birkenhead; from measles in Manchester and Birkenhead; from scarlet fever in Blackburn; and from "fever" in Preston. Of the 29 deaths from diphtheria in the twenty-eight towns, 24 occurred in London. Small-pox caused 1 death in Sheffield, but not one in Greater London, or in any of the twenty-six other large provincial towns. No case of small-pox was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The mortality from diarrhœa did not considerably exceed the average for the season. The deaths referred to diseases of the respiratory organs in London, which had been 199, 189, and 188 in the preceding three weeks, further declined last week to 174, and were 19 below the corrected average. The causes of 80, or 2·0 per cent., of the deaths in the twenty-eight towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Salford, Brighton, Bolton, Blackburn, and in six other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Sheffield, and Bradford.

Digitized by Google

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·8 and 19·5 per 1000 in the preceding two weeks, further rose to 20·9 in the week ending July 23rd; this rate, however, was 1·3 below the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 18·7 and 19·1 in Edinburgh and Aberdeen, to 23·1 in Paisley and 23·7 in Dundee. The 523 deaths in the eight towns last week showed a further increase of 36 upon the numbers in the preceding two weeks, and included 39 which were referred to diarrhœa, 37 to whooping-cough, 9 to "fever" (typhus, enteric, or simple), 8 to diphtheria, 5 to scarlet fever, 5 to measles, and not one to small-pox; in all, 103 deaths resulted from these principal zymotic diseases, against 84 and 93 in the preceding two weeks. These 103 deaths were equal to an annual rate of 4·1 per 1000, which was 2·6 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of diarrhœa, which had increased in the previous four weeks from 10 to 30, further rose last week to 39, of which 16 occurred in Glasgow, 6 in Dundee, and 6 in Paisley. The deaths from whooping-cough, which had been 46 and 43 in the preceding two weeks, further declined last week to 37, and included 14 in Edinburgh, 10 in Glasgow, and 5 in Dundee. The 9 deaths referred to "fever" showed an increase upon the low numbers returned in recent weeks; 5 occurred in Glasgow, 2 in Edinburgh, 1 in Aberdeen, and 1 in Leith. The fatal cases of diphtheria were also more numerous, and included 2 in Edinburgh and 2 in Leith. The 5 deaths from scarlet fever were fewer than in any recent week; 4 were returned in Dundee. Three of the 5 deaths from measles occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 80, 76, and 65 in the previous three weeks, rose again last week to 77, and were 10 above the number returned in the corresponding week of last year. The causes of 74, or more than 14 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 26·6 and 27·9 per 1000 in the preceding two weeks, further rose to 29·9 in the week ending July 23rd. During the first three weeks of the current quarter the death-rate in the city averaged 28·1 per 1000, the mean rate during the same period being but 22·1 in London and 19·1 in Edinburgh. The 202 deaths in Dublin last week showed a further increase of 13 upon the numbers returned in the previous two weeks; they included 21 which were referred to measles, 21 to diarrhœa, 3 to whooping-cough, 2 to "fever" (typhus, enteric, or simple), 1 to scarlet fever, and not one either to small-pox or diphtheria. Thus the deaths resulting from these principal zymotic diseases, which had been 47 and 45 in the preceding two weeks, rose last week to 48, and exceeded the number returned in any previous week of this year; they were equal to an annual rate of 7·1 per 1000, the rates from the same diseases being 8·5 in London, and 4·2 in Edinburgh. The fatal cases of measles, which had been 36 and 28 in the previous two weeks, further declined last week to 21. The deaths attributed to diarrhœa, on the other hand, rose to 21, from 8 and 12 in the preceding two weeks. The deaths from the other zymotic diseases did not materially differ from the numbers in recent weeks. The deaths of infants exceeded the number returned in any previous week of this year, and the deaths of elderly persons also showed a marked increase. Two inquest cases and 2 deaths from violence were registered; and 49, or nearly a quarter, of the deaths occurred in public institutions. The causes of 27, or nearly that 13 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Army.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Staff Surgeon [illegible] has been placed on the retired list of his rank (dated July 19th, 1887).

The following appointment has been made:—Surgeon [illegible] Veasey, to the *President*, for temporary service (dated August 2nd, 1887).

Correspondence.

"Audi alteram partem."

DISEASE AND MEDICAL ATTENDANCE IN WORKHOUSES.

To the Editors of THE LANCET.

SIRS,—A leader in last week's LANCET refers to an inquest held on the body of a patient, who died in the infirmary, St. George's-in-the-East, and, as one or two points in the account of the inquest require further elucidation, I trust you will grant me space for that purpose, and also to comment briefly on the article.

After the patient was admitted to the workhouse, she was warded amongst the aged and infirm, and the ward she occupied was under the supervision of a paid nurse both by day and night. During the night she got out of bed and fell near the fireplace, with her left arm on the fender. Of course there was no fire in the grate. The patient did not appear to be injured by the fall, and after being put back in bed another inmate sat by her side, and the nurse visited the ward from time to time as usual. In the morning when I saw her, she was quite able to walk about, and did not think anything of the injury, which was simply a bruise of the left arm, and not one private patient in a thousand would have called a medical man in the night to see it. As her mind was becoming affected she was removed to the infirmary, when an attack of acute senile mania supervened, and she died. During her residence in the infirmary she was seen at least twice daily by the medical officer or myself, and the former left the infirmary only two days before she died. The relative who called to inquire after her on the Monday was not allowed to see her, as I did not think it desirable for him to do so in the state of mind she was then in, and she had been visited by friends on the previous day. He, however, put too hopeful a construction on my words when he stated that I said she would be all right in a few days.

I do not see that this case affords an illustration of any want of care or attention. Had she been injured by the fall a message would have been sent immediately to the medical officer.

I will now turn to the question of additional medical advice for the inmates of Poor-law institutions, and, at the very outset, beg to express my opinion that the inmates of these institutions receive far more medical aid than most people do at their own homes, and who pay for it. You allow that we are capable men and incapable of any unkindness, but at the same time you think that another opinion might be provided by some means or another. Respecting our capabilities, I think I may say, and without fear of being considered guilty of boasting, that we are quite equal to the average medical man. For Poor-law appointments there is no lack of good candidates, and usually, though perhaps not always, the best are elected. As regards the advisability of providing further medical advice for the recipients of parochial relief, I must say that I think it a question open for discussion. I should be very sorry to stand in the way of anyone from receiving the best medical or surgical advice in a serious illness. It might be argued, and argued with very great force, that medical officers of Poor-law institutions are men of very considerable professional attainments, and fully capable of treating all cases that come under their charge. Again, in London many of the patients in workhouse infirmaries have previously derived all the benefit they can from treatment at hospitals; and should any patient require operative treatment the medical officer does not care to undertake, he can transfer the case to a hospital. Of course, consultants might be appointed, whose advice and assistance should be available when required, and for which they should receive appropriate remuneration. It would never do to allow inmates and their friends to call in medical men when they wished; such a system would upset the working of any institution, and assuredly a medical officer's berth is not such a bed of roses that anyone would wish to make it more unpleasant. We certainly might have some additional help, and I believe it would be found to answer best if given by the appointment of more junior officers. Such assistance would be an advantage to both medical officers and patients, and would

Digitized by Google

be a means of gaining experience in fields of practice particularly useful to recently qualified medical men.

During the past fifteen years or so great strides have been made in medicine and surgery, but I believe in no departments have there been more improvements than in the medical administration of our Poor-law institutions.

I am, Sirs, yours faithfully,

July 26th, 1887. ARTHUR FFLINTOFF MICKLE, M.B.

"SUBSTANTIVE *VERSUS* HONORARY RANK."

To the Editors of THE LANCET.

SIRS,—So many sensible letters, supported by your favourable comments, have appeared in THE LANCET against honorary rank for medical officers in the army, that nothing more seemed necessary to be said. Having, however, just heard from a friend that a medical contemporary supports the idea of honorary rank, and teems with letters in favour of it, I venture to suggest that the wishes of the majority of medical officers are not represented by these letters. Naturally, those wanting honorary rank write; while the contented ones remain, as a rule, quiet. But there is, I believe, no doubt that, if there were any danger of honorary rank being given to us, a large majority of the medical staff and of the Indian Medical Service would support Mr. Stanhope's statement in the House of Commons, that they had no wish for "titles so dissociated from the duties of their honourable profession," and would protest in the words of your correspondent, "Army Surgeon," against becoming "the laughing stock of the army."

I am, Sirs, yours faithfully,

S. L. DOBIE,
Surgeon-Major, 4th Madras Cavalry.

Kamptee, India, July 3rd, 1887.

VAGINAL HYSTERECTOMY.

To the Editors of THE LANCET.

SIRS,—Dr. Braithwaite's interesting paper in your issue of July 23rd contains much controversial matter. I would first congratulate him on his success, and then, briefly as possible, touch on certain of his statements as regards the best method of operating. Not having a copy of THE LANCET before me at the time of writing, I must rely on my memory, which I trust will be found accurate.

Dr. Braithwaite disapproves of the use of instruments for checking hæmorrhage from the vessels in the broad ligament, and deprecates any attempt to secure them without retroverting the uterus. My experience is quite opposed to this, and having operated on two cases, and seen a few others done, I have no hesitation in saying that with the use of properly-shaped strong forcipressure forceps with a firm catch the operation is materially shortened and bleeding quite safely controlled. In my cases the body and fundus were large, hence the broad ligaments were of a greater vertical depth, and my forceps would only clamp their lower two-thirds; but when the body is of the normal size the forceps act admirably, and the operation is less difficult. With these instruments there is no fear of any slipping of ligatures or risk of secondary hæmorrhage from their ulcerating through the coats of the vessels. Dr. Braithwaite disapproves of the use of sponges. I can only say that in my last case, which made an admirable recovery, and which was a case of cervical cancer complicated with pregnancy, I found that a soft flat sponge, folded, with a strong carbolised silk ligature tied round its middle and introduced into Douglas's cavity, was an excellent means of absorbing the blood which came from the uterine side after separating the uterus. When removed at the end of the operation, it brings the peritoneal and mucous surfaces outwards and into contact, and they soon unite; hence, in my view, as in that of many others, there is no need for suturing these surfaces. A large drainage tube with capacious holes should be inserted for a couple of days, and syringing commenced at the end of twenty-four hours, and done at least three times daily or oftener according to the amount and condition of discharge. This is very important. Dr. Braithwaite seems to contradict himself with reference to the propriety of first removing the diseased cervix. Unless the mass be large there is no need for this, as the peritoneum need not be infected in the operation with forceps, but in retro- or ante-version with ligature it may be. There are other points in the operation which I must leave to another occasion, but I feel sure Dr. Braithwaite will agree with me when I say that in the interest of patients I wish he had insisted that no one should attempt the operation without having practised it on the cadaver a few times, and without having seen it done on the living.

With regard to the indications for the operation, its mortality, and its comparison with supra-vaginal excision of the cervix, I am compelled by the most recent information to differ from him and other writers on the subject. On the matter of so-called recurrence, which really means an incomplete operation, we must all wait for time to decide as regards total extirpation; but as Schroeder's cervical excision is at best but a partial operation, and has a mortality of at the best 7 per cent., and an all-round mortality several points higher, and as recurrences have been too frequent, I think every careful surgeon would agree that the mortality is far too high for any partial proceeding, and the recurrence is what he would expect. Now, the most recent mortality results of the complete operation are *nil*—i.e., that two operators have had a series of fifteen or twenty cases without a death,—and I see no reason why experienced operators should not obtain similar results in this country; but even if the expert and all-round mortality were, with recent improved modes of operating, equal to the best results of Schroeder's operation, I should elect the complete operation, as in properly previously examined cases and those proper for the method there is far greater prospect of a permanent cure by the radical plan. To take the pathology of Ruge and Veit (which is some years old, and needs confirmation) as a basis on which to select an operation can only lead to disappointment, for we hardly ever see cases early enough to feel at all sure that we can get well above the disease; and even if it were proved to demonstration that cancer of the vaginal portion always spreads outwards to the lymphatics in the broad ligament, and rarely, or never, upwards along the canal, I hold that the complete operation would enable us to well remove the diseased parts of the broad ligaments in cases which are not too far advanced for any operation. In those extremely rare cases which are seen early enough for Schroeder's operation, there can be no comparison between it and the complete one, for these rare cases are suitable for the former and not for the latter; but in the majority of cases, as we first see them, Schroeder's operation, with its high mortality and frequent recurrence (through incompleteness) is, in my opinion, out of court. The ordinary amputation of the cervix by the écraseur and other means is only admissible in cases of papilloma, and even these have been known to return. So that in dealing with ordinary cases of cancer as we see them, whether of the vaginal portion, cervical canal, or body, it seems to me that elytro-hysterectomy is the best proceeding.—I am, Sirs, yours truly,

Grosvenor-street, W., July, 1887. H. A. REEVES.

THE THERAPEUTICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—At a meeting held last Friday by the kind permission of Dr. Milner Fothergill at his house, the following gentlemen were elected as Executive Council of the above Society, with power to add to their number:—Dr. Milner Fothergill, M.R.C.P.L.; Mr. Haward, F.R.C.S. Eng.; Dr. Stretch Dowse, F.R.C.P.E.; Dr. Prosser James, M.R.C.P.L.; Dr. Saundby, F.R.C.P.L.; Dr. Campbell; and Dr. Illingworth.

A discussion arose, after the reading of a paper on the advantages of this Society, as to the admission as members of *all* registered general practitioners; and it was finally decided that, as the basis of the Society was to be distinctly "unsectarianism," the following should be the rule for eligibility for admission: "That all qualified medical practitioners shall be eligible for membership provided that they have not already avowedly pledged themselves to any exclusive line of therapeutics." If all gentlemen, therefore, who have already sent in their names for membership, who cannot agree to this rule, will kindly write me a card withdrawing from the Society, I shall be much obliged; at the same time I trust that they will be "few and far between." It was felt by the Council that as an "unsectarian" Society it would be destructive to admit as members any holding strongly biased views with regard to therapeutics. This Society is founded for "investigation of all methods of medical treatment now existing, or which may afterwards be introduced," and therefore it stands as a reasonable pro-

Digitized by Google

position that its members should be "from bias free of every kind." It was also unanimously decided that, subject to this rule, ladies who are upon our Medical Register should be enrolled as members, and it was with much pleasure that I handed in the names of Mrs. Garrett Anderson, M.D., and Mrs. Marshall, M.D. There can be no possible objection to the presence of ladies at a Therapeutical Society, and it is a step in the right direction to admit them as a privilege due to their degrees.

Now that the Society is launched, it only remains for medical men, by joining as members, to make it a success. The subscription is placed at 10*s.* 6*d.* at present, but it was decided to raise this after the first 300 names have been sent in. The journal, of course, will not be included in the subscription, a special charge being made for it. The first meeting will take place in October, and the Council trusts that this Society will not be looked upon as a mere metropolitan one, but literally the Therapeutical Society of Great Britain. It will then take its place amongst the older societies as one of the most useful, because of its essentially practical nature.

Thanking you again for the use of your valuable columns,
I remain, Sirs, yours faithfully,

July, 1887. A. GEORGE BATEMAN, M.B., Hon. Sec.

ON THE USE OF THE THERMOPILE AND SECONDARY BATTERIES.

To the Editors of THE LANCET.

SIRS,—Messrs. Coxeter have, at my suggestion, obtained from Prague the thermopile mentioned by Professor Ogston in an article published in THE LANCET on April 30th, p. 867. The thermopile itself has, when acting properly, an electro-motive force of from four to eight volts. The secondary batteries mentioned by Professor Ogston, when charged, have each an electro-motive force of two volts, and the two boxes contain four cells; therefore the whole secondary battery has also an electro-motive force of eight volts. They answer very well for the electric light and for galvano-cautery, and one box (two cells) is quite sufficient to work an induction coil, but they do not possess sufficient power to overcome a high resistance such as is experienced in performing electrolysis. When needles attached to both poles are inserted, for example, into a nævus, no doubt the current strength would be sufficient, for the resistance then experienced is very low; but if only one pole is used for the needle—say, the positive pole,—when every endeavour is made to prevent a slough, and an electrode is attached to the negative pole and placed on some indifferent part of the body, then the electro-motive force is not sufficient to effectually overcome the resistance. If we take the resistance of the body with a needle attached to one pole beneath the skin at 500 ohms, we should only have a current strength of 16 milliampères. In the electrolysis of nævi with the needles attached to one pole we have generally found that we have been obliged to use a current strength of 40 milliampères to produce any destruction of the growth; and, of course, with the electrolysis of uterine fibroids, in which M. Apostoli is said to use a current strength of from 100 to 300 milliampères, the secondary battery, as described by Professor Ogston, would be of very little use. Again, with the employment of the constant current in the treatment of such an affection as sciatica, when both poles are applied to the skin the secondary batteries would give a current strength of about 8 milliampères, and we have found that the best effects are derived from a current of from 10 to 15. It will therefore be seen that for electrolysis and ordinary galvanising it will be more efficacious to still employ primary batteries containing a large number of cells; but for [illegible] lighting, heating small cauteries, and for working [illegible] coils, the secondary batteries, as charged by the thermopile, are, no doubt, "a convenient means of producing electricity for medical and surgical purposes."

I am, Sirs, yours obediently,

W. E. STEAVENSON, M.D. Cantab., M.R.C.P.,
In charge of the Electrical Department at
July, 1887. St. Bartholomew's Hospital.

[illegible] are said to be giving trouble to some [illegible] of Camberwell and its vicinity. A man who [illegible] by these pests thought it necessary to [illegible] at St. Thomas's Hospital.

LIVERPOOL.

(*From our own Correspondent.*)

THE REBUILDING OF THE ROYAL INFIRMARY.

THE removal of the present buildings of the Royal Infirmary and the erection of a new structure on its site are matters of more than local interest. The institution has existed since 1749. The first infirmary, which was erected in that year, was removed in 1836, and replaced by the present structure, which was commenced in 1821 and completed in 1824. The institution, therefore, possesses some antiquarian interest. The present infirmary has afforded clinical instruction to thousands of medical practitioners, past and present, in all parts of the world; while the re-erection of this most important provincial hospital is a matter of interest to all readers of THE LANCET.

THE OLD INFIRMARY.

Proceedings were taken in 1745 to found "an infirmary for the sick and hurt," but a threatened invasion prevented the completion of this, the first medical charity in Liverpool, until four years later. Excellent views are preserved of this building, which was, and must ever remain, memorable as being the scene of Henry Park's first most successful excision of the knee joint. A less creditable circumstance in connexion with this infirmary is that its medical staff constituted an examining board for African surgeons, the name given to the surgeons on board slave ships, for which Liverpool had at that time a most unenviable reputation.

THE PRESENT INFIRMARY.

Partly owing to town improvements, partly to the fact of the old infirmary being inadequate for its purpose, the present one was erected on a site which was then in the eastern suburbs of the town. From the very first its internal arrangements were faulty. As an illustration of this, it may be mentioned that the original plan contained no stairs at all, and these had to be introduced as an after-thought. Since it was first erected the building has been altered, patched up, and added to repeatedly, the result being to create a huge rambling edifice, most inconvenient to everybody connected with it. Still its complete removal will cause a shade of regret to many an old student who may have pleasant recollections of former days spent within its walls.

THE PROPOSED NEW INFIRMARY.

After due deliberation it was decided that the present site should be retained, some additional adjoining ground having been also acquired and added to it. This latter is being rapidly cleared of the old houses which covered it, and the infirmary itself is in process of demolition. Temporary wards have been erected, and additional accommodation provided in the immediate neighbourhood. Mr. Alfred Waterhouse, R.A., the architect, has produced a general design, which will be at once useful and effective, without being unnecessarily ornate. He has selected the dark Liverpool brick for his material, with terra-cotta facings and ornaments, the effect of which, as seen in the recently erected chemical laboratories, is very rich. The executive department will face Pembroke-place (a leading thoroughfare), and contain all the offices, living rooms, and commissariat department. The general plan is that of a long ridge or backbone, this being a general means of access. From one side of this run off three long pavilions; from the other, two towers and a short central pavilion, by means of which last communication is effected with the executive department. The chief features of the interior will be the use of coloured glazed bricks for the walls, of fireproof cement covered with oak parquet for the floors, and of cement ceilings. By this means every portion of each ward will present an impenetrable surface, always capable of easy cleaning. The ventilation will be of the simplest description, reliance being almost entirely placed upon the windows. The wards will be heated partly by steam coils and partly by central open fireplaces, so as to combine the advantages of both systems. The supervision of the drainage has been handed over to the special care of Mr. Rogers Field, a guarantee in itself that this important department will be of the most perfect character. The members of the Building Committee have spared no pains to ensure the success of the new building. They have visited the more recent hospitals to obtain all possible information on the

Digitized by Google

most modern questions, and have had the active and hearty co-operation of the medical staff in their labours. Mr. Mitchell Banks has from the very first devoted himself almost unremittingly to the plans and organisation generally, in which Dr. Alexander Davidson has also lent great help. A description of the proposed new building, with a bird's-eye view engraving, are given in the *Building News* of July 1st.

HOSPITAL SUNDAY AND SATURDAY FUND.

The following sums have been awarded by the Hospital Sunday Committee to the various medical charities:—Royal Infirmary, £2187 10*s.*; Royal Southern Hospital, £1312 10*s.*; Northern Hospital, £1137 10*s.*; Dispensaries, £612 10*s.*; District Nursing Society, £612 10*s.*; Ladies' Charity—Lying-in Hospital, £350; Children's Infirmary, £525; Eye and Ear Infirmary, £437 10*s.*; Homœopathic Dispensaries, £175; Hospital for Cancer, £87 10*s.*; Hospital for Consumption and Diseases of the Chest, £262 10*s.*; Stanley Hospital, £437 10*s.*; Dental Hospital, £21 17*s.* 6*d.*; St. George's Hospital, £21 17*s.* 6*d.*; St. Paul's Eye and Ear Infirmary, £131 5*s.*; Convalescent Hospital, Woolton, £175; Hospital for Women, Shaw-street, £175; Home for Incurables, £87 10*s.*: total, £8750. Amongst the list of the institutions that used to be included in the amount voted was the Netherfield-road Hospital. That institution, however, is now under the management of the Corporation, and the Home for Incurables has taken its place in the list. In addition to the amounts mentioned above the committee resolved to pay over to the treasurer of the Hospital for Women, Shaw-street, the amount of £185. That institution shared the Fund for 1886, but which had been held over.

THE BRITISH ASSOCIATION.

THE final arrangements in connexion with the approaching meeting of the British Association, to be held here next month, are fast being completed, and it is hoped that it will prove to be one of the most successful gatherings the Association has ever had. The support both of private individuals and of public bodies which is being accorded it bids fair to make this hope fully realised. A guarantee fund of upwards of £10,000 has been raised, conversaziones will be held at the Town Hall and at the Jubilee Exhibitions, and more than a dozen excursions have been arranged for, amongst those who have invited the Association to their seats being the Duke of Devonshire and the Duke of Westminster. The sections, eight in number, into which the work is divided all promise plenty of material for consideration, and the biological section will be of special interest. More than a hundred acceptances have been received from distinguished men from all parts of Europe and America, and it is thought not impossible that the meeting may be graced by the presence of a distinguished member, the Emperor of Brazil, who is at present on a visit to Europe. It is twenty-six years since the last meeting of the Association was held in Manchester.

VOLUNTEER MEDICAL STAFF CORPS.

The first annual inspection of the Manchester division of the Volunteer Medical Staff Corps was held on the 16th inst., when Deputy Surgeon-General A. Bradshaw (the principal medical officer of the northern district) was the inspecting officer, and expressed himself well pleased with the manner in which the men went through the various drills and treated the supposed "cases" on which they had to practise. The enrolled strength of the corps is fifty-eight, and much credit is due to Surgeon Crookwell (who is in command) for the satisfactory manner in which the men acquitted themselves. On the same day the Artillery Volunteers were inspected by Colonel Maclaverty, and two "stretcher detachments" marched past at the rear of the brigade, the latter having recently been through the prescribed ambulance course under the instruction of Drs. Tomkins and Daly, surgeons to the regiment.

OPEN SPACES, ETC.

Mr. Herbert Philips, whose zeal in the matter of open spaces is beyond all praise, is making earnest appeal for more assistance from the well-to-do in furtherance of these objects. The Society of which he is chairman has spent £2000 during the past year in laying out and providing the necessary appliances for gymnasia and recreation grounds in various parts of the city, but, like many other institutions, it is cramped for want of funds. It is gratifying to see that the Corporation are also alive to the importance of this matter, and it is hoped that ere long the large space around St. Michael's church may be utilised much more fully than at present as a playground, &c. The "children's holiday" fund committee have issued their annual appeal for help in sending children out from the slums into the country for a few weeks each. Already this summer some 500 have been thus sent into the surrounding country, and this good work is only limited by the amount of money at disposal.

SCARCITY OF WATER.

The long-continued drought is beginning to assume somewhat serious aspects. Upwards of twenty million gallons of water are required daily for the needs of this great population, and the present quantity in store is running dangerously low. The supply is now cut off between the hours of 8 P.M. and 5 A.M., and economy of consumption is earnestly urged upon everyone. The state of the river Irwell this dry season is giving rise to loud and bitter complaint. The fact is, the stream is little better than an open sewer, and gives off, in places, the most vile smells. Mr. Alderman Walmsley, one of the medical representatives on the Salford Corporation, has addressed some very strong letters to the papers, in which he says the stench in the neighbourhood of the Broughton Cricket-ground is positively dangerous. This is particularly hard on the Salford residents, seeing how much Salford herself has done to prevent the fouling of the river. A boy who recently fell in was rescued from drowning, but died within two days, and a verdict was returned that he died from poisoning, "the effects of the filthy water of the Irwell." *Verb. sap.*

ROYAL INFIRMARY.

The annual meeting of the Royal Infirmary is to be held on the 28th, and in the abstract of the report now issued it is stated that ten years ago each occupied bed cost £74 per annum, whilst in the past year it was only £42. But it is somewhat fallacious to pick out any two years for the purposes of comparison; it would be much better to take, say, the average of the past ten years, since the new management came into operation, and compare it with the average of the preceding ten years. The in-patients under treatment during the past year have been 5308 at the infirmary, 1279 at the convalescent hospital, and 1755 in the fever hospital, the cost per bed at this latter institution still appears to be high even for an infectious hospital.

NEW FEVER HOSPITAL.

The proposal of the Salford Corporation to acquire land at Hope for the erection of a new Fever Hospital in place of the one soon to be removed at Cross-lane, is giving rise to much opposition; and an organised movement to prevent if possible its erection on this site is in progress.

July 28th.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

ACCIDENTS IN NORTHERN MINES.

THE annual reports of the inspectors of mines to the Home Secretary were issued yesterday morning. Mr. James Willis, reporting on the Newcastle-on-Tyne district, which embraces the north part of the county of Durham, the counties of Northumberland and Cumberland, and detached parts of Lancashire, shows that the number of persons employed was 52,643, as against 53,011 in 1885. There had been thirty-six fatal accidents in the course of the year, each occasioning the loss of one life. This is a larger number of fatal accidents than the preceding years, but the loss of life is very much less. Mr. Willis shows that the accident figures compare favourably with those of the United Kingdom. Mr. Thomas Bell, inspector of the Durham district, which embraces South Durham, Westmoreland, and the North Riding of Yorkshire, reports that
